Welcome

We are thrilled and honoured to host this important event from 2-5 July 2024 – the first time the congress has come to Scotland.

Glasgow is the largest city in Scotland and is renowned for its rich cultural heritage, including its contributions to art and architecture, vibrant music and nightlife scenes and its role in the Industrial Revolution. It boasts the largest academic community outside London and world-leading research in life sciences, engineering, science and technology. Cultural attractions include the works of Charles Rennie Mackintosh and many museums and art galleries offering free entry.

Glasgow is internationally recognised as a 'city of sport', having hosted numerous international sporting events, including the Commonwealth Games 2014 and European Championships 2018. In 2023, the city hosted the first-ever unified UCI World Cycling Championships – the largest ever cycling event. Glasgow is also home to two of Scotland's most successful and well-known football teams, Celtic and Rangers. These two clubs have a fierce and longstanding rivalry, known as the 'Old Firm', which has become one of the most iconic rivalries in sport.

The congress will take place in the Scottish Event Campus (SEC) featuring a mix of three different buildings – the SEC Centre, the Armadillo and the OVO Hydro. This multi-award-winning campus has played host to a variety of prestigious global conferences, including the UN Climate Change Conference COP26. Our ECSS Congress will be held within the SEC Centre and the iconic Armadillo building. The venue is surrounded by hotel accommodation and is a short distance from Glasgow's City Centre. The food and drink scene offers something for everyone, from traditional whisky pubs to fine dining, in a variety of lively neighbourhoods including Finnieston (SEC), the City Centre, the West End and Merchant City.

Enhancing Health, Performance and Community Sport is the theme for the ECSS Congress in Glasgow and reflects a broad programme of scientific presentations across all sport and exercise disciplines. We also welcome the opportunity to support innovative pre-congress symposia which bring together sport industry, business and the scientific community.

With such a rich cultural heritage we aim to create a diverse and vibrant social experience at the congress and guide you to the wider cultural opportunities while you visit Glasgow and Scotland. We would also encourage you to extend your stay and sample the great hospitality both in Glasgow and the many great tourist destinations across Scotland.

We invite you to ECSS 2024 in Glasgow and look forward to providing a great event and an unforgettable cultural experience.

Yours in Sport Science,

The ECSS Glasgow 2024 Organising Team

Prof R.C. Richard Davison (Congress President)

Invited Symposium

IS-MH09 Improving health and wellbeing with a minimal dose of high-intensity exercise; can we make it work?

VERY LOW VOLUME SPRINT INTERVAL EXERCISE FOR IMPROVING HEALTH AND FITNESS: WHAT IS THE EVIDENCE?

METCALFE, R.
SWANSEA UNIVERSITY

Over the last ~15 years there has been considerable interest in the effects of high-intensity interval training (HIIT) upon health. Much of this research has focused on sub(maximal) HIIT protocols (e.g., 10 x 1-min efforts with 1 min recovery), as these are perceived to be more applicable for unfit and inactive individuals and/or patient populations. However, the need for multiple high-intensity efforts still makes these protocols demanding to perform, while also reducing the overall time-efficiency that is one of the key proposed benefits of HIIT. At the same time, sprint interval training (SIT) – a specific form of HIIT involving repeated 'all-out' sprint efforts – has been largely dismissed as a viable form of exercise for improving health. Yet, a growing body of evidence demonstrates the efficacy of SIT protocols with fewer (as little as two repetitions) and shorter (10-20 s) sprints for improving important risk factors for chronic disease. These SIT protocols involve extremely low doses of exercise (40 s per session) and a minimal total time commitment (20-30 min per week), making them shorter and easier and removing many common barriers to HIIT and to exercise in general. Nevertheless, there are many common misconceptions about very low volume SIT protocols amongst both academic researchers and practitioners. A common one is that "this cannot possibly be enough exercise to actually be effective!". At face value this is reasonable – that as little as 40 s of exercise could elicit beneficial adaptations is an extraordinary claim. However, when viewed through the critical lens of the physiological and molecular responses to acute sprint exercise, it is a much less surprising, and even expected, finding. The purpose of this talk is to critically discuss the mechanistic basis for physiological and health-related adaptations to occur with minimal doses of sprint interval exercise. The current evidence for the effects of very low volume SIT on health and fitness parameters (e.g., cardiorespiratory fitness, insulin sensitivity, etc) will then be discussed, with avenues for future research highlighted.

EXERCISE AT HIGHER INTENSITIES MAKES PEOPLE FEEL WORSE, BUT DID WE OVERLOOK THE INFLUENCE OF SHORTER EXERCISE DURATION?

VOLLAARD, N.
UNIVERSITY OF STIRLING

An increasing body of evidence supports the lab-based efficacy of interval protocols involving brief repeated bouts of (sub)maximal exercise (high-intensity interval training [HIIT]) or supramaximal exercise (sprint interval training [SIT]) to improve general health and reduce risk of a range of noncommunicable diseases. However, whether HIIT and/or SIT can be used as effective real-world interventions remains a topic of debate. Concerns have been voiced that the high exercise intensities involved with HIIT and SIT will substantially decrease participants' affective valence, reducing exercise enjoyment and self-efficacy, and ultimately leading to poor uptake and adherence. Research solely based on continuous exercise confirms links between exercise intensity and changes in affective valence, as well as between changes in affective valence and future physical activity behaviour. However, HIIT and SIT are not continuous exercise, and HIIT is not SIT: these are distinct exercise interventions encompassing widely divergent protocol parameters (e.g., sprint intensity and duration, number of repetitions, recovery interval duration, training frequency, mode of exercise). Recent evidence supports that modulating sprint duration and number of sprint repetitions can substantially alter in-task affective responses to HIIT and SIT. Moreover, emerging evidence refutes the proposed links between changes in affective valence and exercise enjoyment, as well as between changes in affective valence and future physical activity behaviour. Dr Vollaard will argue that very low volume SIT protocols may represent acceptable interventions for improving health markers in the general public and specific patient populations. This talk is intended to be of relevance to researchers with a general interest in the area of physical activity and health.

IMPROVEMENTS IN GLUCOSE METABOLISM AND INSULIN SENSITIVITY WITH INTERVAL EXERCISE: IS IT A HIIT IN FEMALES?

GILLEN, J.
UNIVERSITY OF TORONTO

High-intensity interval exercise (HIIE) is touted as a time-efficient strategy to improve indices of cardiometabolic health including glycemic control and insulin sensitivity. The benefits of HIIE on glycemic control and insulin sensitivity include improvements observed during and up to 24 hr following a single session of exercise, and those which accrue from repeated sessions of exercise over weeks or months (i.e., following chronic exercise training). While a number of studies have now documented the glycemic benefits of HIIE, there is evidence that females do not achieve the same improvements in this important health outcome as males. It has been suggested that sex differences in skeletal muscle metabolism, including cellular stress and fuel metabolism, may explain the difference in the insulin-sensitizing effects of HIIE in males and females. In this session, an overview of the effects of HIIE on glycemic control and insulin sensitivity will be provided. Dr Gillen will then highlight the evidence demonstrating sex differences in the response, providing both possible mechanisms and confounding factors in study designs that could explain these findings. Dr Gillen will also highlight recent data from her lab demonstrating that manipulating the timing and macronutrient composition of meals around exercise may be a strategy to optimize the glycemic benefits of HIIE in females. Finally, Dr Gillen will identify gaps in knowledge for future research and provide recommendations for best practices in research designs investigating both sex-based differences and women's health in response to exercise. This talk will be of interest to researchers and practitioners with interests in exercise physiology, muscle metabolism, women's health, nutrition, and diabetes.

Invited Symposium

IS-BM01 Energetics and mechanics of human locomotion: insights from a muscle and tendon perspective in determining the mechanical and energetic responses

THE INFLUENCE OF MUSCLE AND TENDON BEHAVIOR IN DETERMINING THE MECHANICAL AND METABOLIC RESPONSES DURING WALKING IN HEALTHY AND PATHOLOGICAL POPULATIONS

MONTE, A.
UNIVERSITY OF VERONA

Over the last decades, human walking has been considered an inverted pendulum where the potential and kinetic energies of the body center of mass are out of phase and continuously exchange, reducing the total mechanical energy oscillations over a stride. On the other side, from an energetic point of view, the metabolic energy expended to cover one-unit distance as a function of speed was empirically described by a quadratic (U-shape) function that shows a minimum at a speed of about 4-5 km.h-1, often called the "optimal walking speed". Thanks to this whole-body approach, it was possible to describe the salient characteristics of human walking in healthy and pathological situations. Therefore, the first aim of this study is to provide a comprehensive description of human walking at the whole-body level. Along this line of reasoning, within the last years, several researchers have tried to explain the changes in metabolic and mechanical demands of walking from muscle and tendon perspectives in order to discover new training strategies and therapies to counteract the loss of function imposed by several conditions. In this regard, using a combination of ultrasound, EMG, kinematic and dynamometric measurements, we observed that changes in muscle fascicle behaviour imposed by an increase in walking speed could partially explain the changes in the metabolic cost as well as the transition between walking and running; while this was not the case for the behaviour of the elastic tissues. Hence, the second aim of this presentation is to report the influences of muscle and tendon behaviour in determining the energetics and mechanics of walking as a function of speed, in order to understand how their modification could affect the biomechanics of walking in pathological situations. Finally, I will report new data from experimental studies, in which the behaviour of plantar flexor muscle fascicles and the Achilles tendon have been investigated during walking at different speeds in people with type 2 diabetes, pre and post ten weeks of stretching training program. Our preliminary data showed that the increases in energy cost of walking, typically observed in people with type 2 diabetes, could be partially counteracted by using a simple stretching training protocol. In this regard, stretching was able to modify the stiffness of the Achilles tendon, leading the muscle fascicles to operate in a more favourable portion of the F-L and F-V curves, finally reducing the energy cost of walking. In the last part of this talk, final remarks and future directions will be provided and discussed.

THE DYNAMIC INTERPLAY OF TRICEPS SURAE MUSCLE AND TENDONS IN OPTIMIZING THE METABOLIC COST OF RUNNING

VANWANSEELE, B.
KU LEUVEN

Over the last decades it has become more and more recognized that running has played a major role in human evolution. Compared to other (quadrupedal) animals, humans are very average sprinters, but we perform surprisingly well at endurance running. Nowadays running is among the most popular physical activities worldwide, primarily because its accessibility and association with health benefits. Watching runners passing by, there are substantial differences in how

individuals run. Despite the large body of running research, research into the underlying mechanisms explaining the variability in running patterns is very limited. A commonly used and widely accepted hypothesis to explain why humans move the way they do is that we optimize performance (e.g. minimize certain neuromuscular cost function while performing the movement). There is scientific evidence that humans seem to be able to self-optimize their running pattern, as they adopt a specific running gait, e.g. stride frequency, stride width, foot strike pattern, associated with minimal energy consumption. Hence, energy minimization is often assumed to be one of the major neuromuscular mechanisms underlying the preferred running pattern. However, why a certain running pattern requires less energy, and is thus more optimal, than another for a specific runner is still an open question. Skeletal muscles are the tissues consuming the majority of energy during running. Hence, explaining the metabolic cost of running from a muscular perspective is an important next step to enhance our insights on the metabolic cost of running. However, the metabolic cost of the muscles during running cannot be measured directly. We therefore need to use a combination of experimental and simulation approaches combining motion capture, EMG, ultrasound with musculoskeletal modelling and muscle metabolic cost models. I will first explain how we modified existing musculoskeletal models to represent better experimental measures. Then, I will present the results from several studies using this approach to investigate how triceps surae muscle-tendon interactions affect whole-body and muscle metabolic rate during preferred and adjusted running patterns. I will present data on the effect of changes of speed, stride frequency and foot strike pattern on triceps surae fascicle length, length changes and simulated metabolic energy. Increasing the running speed increased triceps surae metabolic cost through an increase in muscle forces and changes in muscle-tendon interaction. While changing foot strike pattern had the opposite effect on the muscle forces and muscle fascicle length changes, resulting in no differences in muscle metabolic energy and whole-body metabolic energy. Lastly, I will present the results on how stride frequency influences muscle fascicle behavior and how changes in whole-body metabolic energy consumption can be explained by a combination of muscle fascicle behavior and muscle activation.

SPECIFIC MUSCLE CONTRACTILE CONDITIONS PROMOTE LOCOMOTOR ECONOMY, SPRINT PERFORMANCE AND PERTURBATION-RECOVERY

BOHM, S.
HUMBOLDT-UNIVERSITÄT ZU BERLIN

Human locomotion covers a broad range of speeds and is driven by the generated forces of the lower limb muscles. To sustain submaximal running for a longer period of time, economical muscle force generation and efficient muscle work production may optimize the metabolic cost. However, when increasing speed to the maximum, high mechanical power production is needed at the expense of metabolic energy cost. Moreover, real-world environments rarely allow for stable and constant locomotion. Most often, the locomotor behavior faces unsteadiness and external environmental perturbations that challenge the neuromuscular system to generate compensatory muscle forces for the maintenance of the stability of the body. A muscle's mechanical output is dictated by its operating contractile conditions, particularly the fascicle length and velocity during the movement with respect to the intrinsic force-length, force-velocity, power-velocity and efficiency-velocity relationships. The decoupling of the muscle fascicle length changes from the muscle-tendon unit due to the compliance of the attached tendon and the fascicle rotation (changes in pennation angle) provides regulatory mechanisms of the operating muscle length and velocity. Furthermore, previous in vitro and in situ evidence suggest that the force-length relationship depends on the activation level, i.e. optimal length for force generation shifts towards longer length at decreasing activation levels. This activation dependence reasonably influences the force generation during movements with variable activation pattern. The talk will present current experimental findings on the contractile conditions and activation of the soleus, as the main muscle for propulsion, during steady and perturbed locomotion. We found that during submaximal running, the soleus fascicles shorten close to optimal length and at a velocity close to the efficiency-maximum, two contractile conditions for economical work production. At high and maximum running speeds, the fascicles still operate near optimum length, yet the fascicle shortening velocity increase and shift towards the optimum for mechanical power production with a simultaneous increase in muscle activation, indicating three cumulative mechanisms to enhance mechanical power production. Furthermore, our preliminary results show how the contractile conditions and activation of the soleus muscle contribute to compensatory muscle force generation in response to a walking perturbation induced by an unpredictable drop in surface height. Particular attention will be given to the regulatory effect of the fascicle decoupling by tendon compliance and fascicle rotation as well as to the influence of the activation dependence of optimal length on the soleus muscle contractile conditions during the different running speeds and stability recovery response.

Oral Presentations

OP-AP07 Training and Testing/Power and Strength I

THE EFFECTS OF THREE CONTRAST TRAINING SESSIONS IN A WEEK ON POST-ACTIVATION PERFORMANCE ENHANCEMENT IN HIGH STRENGTH MALE

CHEN, C.M.1, CHENG, K.2, LI, T.1

1NATIONAL TAIWAN SPORT UNIVERSITY; 2NATIONAL TAIWAN NORMAL UNIVERSITY

INTRODUCTION: Previous studies indicated that the primary contributor of contrast training improving explosive performance might be the post-activation performance enhancement (PAPE) and further emphasizing to conduct plyometric training at the optimal PAPE time. However, its applicability in practical training is not yet clarified since the PAPE appeared to be influenced susceptibly by relative strength level, training protocol, fatigue, and etc. Thus, the purposes of this study were to: 1) examine the effects of three contrast training sessions in a week on individual and group's PAPE and the optimal PAPE timepoint. 2) assess the intrasession reliability of the optimal PAPE timepoints.

METHODS: Eighteen trained male (age, 23.2 ± 3.3 years; body mass, 73.5 ± 8.9 kg; parallel back squat 1-repetition maximum [1-RM], 154.7 ± 22.9 kg and relative parallel squat 1-RM, 2.11 ± 0.21 kg·kg-1) performed three contrast training sessions, which consists of three sets of three repetitions of parallel squats at 90% 1-RM in a week. Alongside this, countermovement jump (CMJ) tests were conducted before the first set of squats and at 1, 3, 5, 7, 9, and 11 minutes after each squat set, with the kinematic parameters of the parallel squats also being collected. Data analyzed using Cochrans Q test, repeated measures one-way ANOVA with post hoc Bonferroni, and coefficient of variation (CV). Statistical significance was set at $\alpha = .05$.

RESULTS: Sixteen participants experienced individual PAPE whose data was adopted in statistics. The occurrence percentage of individual PAPE at nine sets of contrast training was significant difference (12/16, 5/16, 1/16, 10/16, 9/16, 8/16, 7/16, 2/16 and 4/16; Cochrans Q test, $p < .001$). The intrasession CVs of the optimal PAPE timepoints in three contrast training sessions were 60.9%, 59.4% and 39.6%, respectively. No group' PAPE was found at any sets of the three contrast training sessions. Concentric mean velocity of squat decreased at the second and third set compared with the first set in every contrast training session ($P < .05$), whereas the velocity loss of squat decreased at the second and third set compared to the first set only in the first and second training session ($P < .05$).

CONCLUSION: The findings of this study indicated that the reliability of the optimal PAPE timepoints was inconsistent and varied with the numbers of set and training session, even absent. It was also suggested that the arrangement of plyometric training based on the PAPE during contrast training might not be practicality.

THE INFLUENCE OF BACK SQUATS IN COMBINATION WITH REACTIVE STRENGTH TRAINING OR STRENGTH TRAINING OF THE PLANTAR FLEXORS ON SPEED AND JUMP PERFORMANCE IN YOUTH ELITE SOCCER PLAYERS

KADLUBOWSKI, B., KEINER, M., WIRTH, K., CSAPO, R.

UNIVERSITY VIENNA

INTRODUCTION: Soccer, characterized by dynamic movements like sprinting, jumping, and directional changes, heavily relies on explosive actions for scoring goals [1]. One crucial factor in facilitating rapid force development during these actions is the stretch-shortening cycle [2]. Despite numerous studies investigating training interventions to enhance speed and jumping ability in soccer players, there is still a gap in our under-standing regarding the effectiveness of isolated plantarflexor muscle strength training [3]. This study aimed to compare the effects of combined training interventions incorporating back squats with either calf raises or plyometric training, on the linear sprint and jump performance of youth soccer players.

METHODS: A longitudinal six-month training study was conducted with male youth soccer players (n = 89) from two elite youth training centers in Germany. Participants were divided into two intervention groups (PLY-BS, plyometric exercises + back squat; CR-BS, back squat + calf raises), and a control group (CG), which per-formed the conventional soccer-specific training only. Outcome measures included back squat and calf raise one-repetition maxima (1-RM), linear sprint times (5m, 10m, 30m) as well as the performance in countermovement jumps (CMJ) and drop jumps (DJ) from heights of 15cm, 30cm, 45cm, and 60cm.

RESULTS: A mixed factorial ANOVA showed that 5m LS times were affected by time ($p<0.001$), with 1.8% reduction post-training. Group and time × group interaction effects were non-significant. For 10mLS, the effect of time ($p=0.01$) was significant. A statistical time × group interaction effect ($F(2,78)=8.599, p<0.001, \eta p2=0.181$) showed that training-induced improvements were larger in CR-BS and PLY-BS than in CG Similarly, CMJ performance improved over time ($p<0.005$) and differed between groups ($p<0.05$). The significant time × group interaction ($p<0.005$) demonstrated that the improvements over time were greater in CR-BS and PLY-BS than in CG.

CONCLUSION: Our findings indicate that implementing combined training interventions, which involve combining back squats with either calf raises or plyometric exercises, can significantly enhance sprint and jump perfor-mance among youth soccer players. This underscores the pivotal role of targeted strength and condition-ing measures in soccer training

programs. Notably, for improving drop-jump performance, it appears that calf raises yield superior outcomes compared to plyometric training.

DIFFERENCES IN MUSCLE STRENGTH AND JUMPING PERFORMANCE ADAPTATIONS BETWEEN HIGH-LOAD AND LOW-LOAD FLYWHEEL SQUAT RESISTANCE TRAINING INTERVENTIONS

SPUDIC, D., PRIMOŽ, P., VOJKO, S., NEJC, Š., IGOR, Š.

UNIVERSITY OF LJUBLJANA

INTRODUCTION: Quantification of load magnitude is a limitation in flywheel (FW) resistance training protocols. Adaptation mechanisms for muscle strength and jumping performance improvement are velocity-specific [1]. However, it is unknown whether this specificity extends to the FW modality. Force-velocity-power (FvP) profiling has been proposed to assess neuromuscular characteristics of lower extremities in FW squats [2,3]. This method could also be utilized to individually allocate the magnitude of FW load [4]. This study aimed to evaluate the differences in adaptations of leg strength and jumping performance after FW squat resistance training performed under low and high loading conditions.

METHODS: Physical education students were randomly assigned to two training groups and a control group. The training groups engaged in eight weeks of FW squat resistance training, 2-3 times per week, with low and high inertial loads. Individual load determination was based on FvP profile characteristics obtained during FW squats. The low-load group (n = 16) performed squats with the FW load that maximized power output, and the high-load group (n = 18) used a load corresponding to 70% of maximal theoretical power. The control group (n = 13) received no intervention. Various tests were conducted, including isometric knee extension strength and rate of force development (RFD), squat jump (SJ), countermovement jump (CMJ), FvP profiling in FW squats and CMJs. Mechanical and electromyography (EMG) variables were measured, along with an ultrasound assessment of vastus lateralis (vl) muscle thickness, pennation angle, and fascicle length. A mixed model analysis of variance with factors time (pre, post) and group (C, low-load, high-load) was performed to reveal differences in adaptations between groups over time.

RESULTS: FW squat training induced improvements (all $p < 0.05$) in: knee extension strength; SJ RFD, force and power; CMJ height, force and power in concentric and eccentric phases; FW FvP profile outcomes in the concentric phase and the maximal theoretical force in the eccentric phase; CMJ FvP profile maximal theoretical velocity and power; vl muscle thickness and pennation angle. No significant differences were found in the adaptations between the two training groups ($p > 0.05$).

CONCLUSION: FW squat resistance training emerged as an effective modality for enhancing the strength, power, and jumping abilities of athlete students. Interestingly, the magnitude of the FW load did not show a statistically significant influence on the observed adaptations. There was a trend toward higher changes in mechanical variables and muscle architecture in the high-load group. The improvements in mechanical variables were more strongly associated with the adjustment in vl muscle thickness than with neural activation enhancement, irrespective of the motor test performed.

HIGH COGNITIVE EFFORT PRIOR TO VELOCITY-BASED TRAINING SESSIONS INHIBITS RATE OF FORCE DEVELOPMENT, BUT NOT MAXIMUM STRENGTH GAINS IN UNTRAINED ADULTS

ALVES ARAUJO DE LIMA JUNIOR, D.R., BOULLOSA, D., ROELANDS, B., FERREIRA, M., FORTES, L.

UNIVERSITY OF BOLOGNA

INTRODUCTION: The objective of this study was to analize the repeated effect of high cognitive effort immediately prior resistance training sessions on neuromuscular performance in untrained adults.

METHODS: We therefore employed a mixed experimental design, with the group as the between-participant factor and time as the within-participant factor. The thirty- four participants were randomly assigned to two parallel groups: high cognitive effort (n = 17) and control (n = 17). The control group maintained seated during 30 min before resistance exercise sessions while the high cognitive effort group made incongruent trials of the Stroop task until subjective mental fatigue was present immediately prior start resistace exercise sessions. Participants attended 45 sessions over fifteen weeks, consisting of three familiarizations, three baseline evaluations, 36 resistance training sessions, and three post-experiment evaluation sessions. Rate of force development (RFD) for isometric mid-thigh pull, half-back squart 1-RM, and countermovement jump (CMJ) was measured before and after the 12-week intervention.

RESULTS: A significant group x time interaction effect was found for the average RFD 0-250 ms ($p<0.05$), with greater improvements for the control group than for the high cognitive effort group. There was no effect of group x time interaction for half-back squat 1-RM ($p>0.05$). Also, there was no effect of group x time interaction for CMJ ($p>0.05$).

CONCLUSION: In conclusion, repeated high cognitive effort immediately prior to resistance training sessions impaired the improvements in RFD, although this did not inhibit the increased performance for half- back squat 1-RM and CMJ in male untrained adults.

OP-AP05 Football Statistics

SUPER SIZE SOCCER – ALTERATIONS OF PITCH DIMENSIONS REVEAL HYSTERESIS IN TEAMS' COLLECTIVE BEHAVIOR

DEUKER, A., BASSEK, M., WITTKUGEL, J., BRAUNSTEIN, B., REIN, R., RAABE, D., VOGT, T.
GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: Sports teams are frequently interpreted as (dynamical) systems to examine their collective behaviors, (CB; i.e., states) under stable environmental conditions (1). However, it is unknown whether the states of such a system are time-dependent, i.e., sensitive to previous environmental conditions (2). One particularly suitable system to study this dependency is soccer teams, where variations in pitch dimensions across contexts, e.g., from training to competition, are pervasive. The present study examines time-dependency by investigating hysteresis effects in the spatial organization of soccer teams responding to systematic changes in pitch dimensions.

METHODS: Twenty-two male soccer players (6th division or higher) participated in a 11-vs-11 crossover, controlled, trial-based approach (3). They were instructed to perform an organized attack in 4-4-2 formation. Following six warm-up trials on an official-sized pitch (105x68 m; 7,140 m²), twelve experimental trials were conducted across four pitch size conditions (50%, 100%, 150%, 200%). To observe time-dependent adaptations in CB, each team performed three experimental trials per condition, scaling UP from 50% pitch size to 100%, 150%, and 200%. After a short break, this procedure was reversed, scaling DOWN from 200% back to 50%, totaling 54 trials. Player positions were tracked using GPS (10Hz) and verified with video footage. For each trial, effective playing space (EPS), team spread, stretch index, and relative field usage were calculated as parameters of CB. Multiple linear regression was employed to assess the influence of pitch size (50%, 100%, 150%, 200%), scaling direction (UP, DOWN), and their interaction on the CB.

RESULTS: Linear regression analysis resulted in significant main effects for pitch size across all calculated CB parameters (EPS, team spread, stretch index, relative field usage; $p<.0001$). Interaction effects between pitch size and scaling direction were significant for EPS ($p=.04$), team spread ($p=.05$), relative field usage ($p=.03$), and a trend towards significance in the stretch index ($p=.06$). Hysteresis was particularly present at 50% pitch size, with average differences between UP- and DOWN-scaling as follows: Stretch index delta of 1.07 m, relative field usage of 3.5%, EPS of 127 m², and team spread of 14.5 m. These findings indicate time-dependency of changes in CB.

CONCLUSION: The discovered hysteresis effects provide empirical evidence for a time-dependency of soccer teams states on historical environmental conditions. This result demonstrates how a (dynamical) systems perspective on soccer teams may lead to important insights, showing that soccer teams CB is highly sensitive and adaptable to previous stimuli. Better understanding the dynamics of team system configuration in sports contexts is a fertile ground for future research.

GAZE STRATEGY AND ANTICIPATION OF DEFENSIVE SITUATIONS IN YOUTH PERFORMANCE SOCCER – AN EYE-TRACKING PILOT STUDY

HERDEN, M., ADAMI, T., EHSANI, B., SCHUMACHER, N.
UNIVERSITY OF HAMBURG

INTRODUCTION: In fast-paced team sports like soccer, defenders anticipation skills are crucial in decisions-making, often determining success or failure [1]. Studies show that expert athletes use more effective visual search strategies and focus on more relevant areas than less experienced athletes, implying that gaze behaviour such as saccades and fixations may be relevant for anticipation and successful decisions in soccer [2]. The aim of this pilot study was thus to investigate differences in gaze behaviour with correct or incorrect decisions in young elite soccer players.

METHODS: The study enrolled 10 young elite soccer players, including six defenders and four offensive players aged 16-18 years, (16.7 ± 0.68) with an average of 11.2 years of soccer experience. Participants viewed standardized videos of 48 defensive 1:1 game situations which were occluded at -150, -300, and -450ms before the critical last ball contact. Study participants were instructed to decide within 10 seconds after occlusion whether the opponent player depicted in the video was about to run to the left or right. Gaze behaviour was registered with an Eye Tracking System (Tobii Pro Glasses 3) measuring total saccades and fixations. Fixations were analysed with respect to regions of interest defined by Krzepota et

al [3]. Differences between correct and incorrect decisions with regard to total saccades and fixations were calculated using the Mann-Whitney-U Test. The alpha-level was set at 0.05.

RESULTS: Significant differences were observed for total saccades (p = 0.026), fixations at the "zone-in front of-of the-ball/ foot" (p = 0.008), and the "zone beyond the player and ball" (p = 0.020) at -300ms while correct decisions showed more total saccades, shorter fixation duration at the "zone in front of the ball" and longer fixation duration at the "zone beyond the player and ball". Video sequences at occlusion timestamps of -150ms and -450ms revealed no significant differences between correct or incorrect decisions.

CONCLUSION: The differences in gaze behaviour (saccades and fixations) underline their importance in correct decision-making. Young soccer players may make better decisions with respect to anticipated opponents' movement when they exhibit more saccades and shorter fixation duration at the "zone in front of the ball". Future research should explore integrating gaze strategies into training and further investigate the relationship between saccades, player position, and decision accuracy.

MATCH DIFFERENCES BETWEEN DIFFERENT THRESHOLDS OF ACCELERATIONS AND DECELERATIONS IN ACADEMY SOCCER PLAYERS

VAMPOLA, J., ŠTASTNÝ, P., VARJAN, M., MALÝ, T., MUSÁLEK, M., CASTELLANO, J., KOKŠTEJN, J.

CHARLES UNIVERSITY

INTRODUCTION: According to previous studies on the neuromuscular demands (Harper et al., 2019), professional football is more decelerative than accelerative. However, it is not known whether this is respected in terms of intensity ranges. The aim of the study is to compare whether this trend in favor of deceleration is maintained in the different intensity ranges.

METHODS: External load from official competitions in three age categories (2nd team, 20.8 ± 4.4 yrs; U19, 17.0 ± 0.7 yrs; and U17, 15.8 ± 0.6 yrs) of elite football academy were measured by 10 Hz GPS technology during two consecutive seasons, 2021/22 and 2022/23. 2nd team played in third and second professional Czech leagues, both youth teams played the highest youth competitions. Various thresholds were used for examining the number of accelerations (ACC) and decelerations (DEC): ACC12 (from 1 to 2 ms-2), ACC23 (2-3 ms-2), ACC34 (3-4 ms-2), ACC45 (4-5 ms-2), ACC5 (>5 ms-2), with negative sign for decelerations (from DEC12 to DEC5), respectively. From official matches with 4-3-3 formation in which the players participated for the entire duration (>90 minutes), were calculated averages for every player/season. Repeated measures ANOVA with Bonferroni's post-hoc test, Student t pair test and Wilcoxon signed-rank test were used (JASP, Version 0.18.3). Cohen´s d values were employed to assess effect sizes. Effect magnitude was interpreted according to power analysis (G*power, version 31.9.7).

RESULTS: ANOVA revealed a significant influence of category on the results. Significant differences were found in all parameters only between the 2nd team and U17, although with small effect sizes according to power analysis ($p<0.05$, d= 0.47-0.60). There were found, in all categories, greater number of ACC than DEC in thresholds of 2-3 ms-2 (ACC23>DEC23) and 3-4 ms-2 (ACC34>DEC34). In all other thresholds more decelerations were found (ACC12 < DEC12, ACC45 < DEC45, and ACC5 < DEC5). In the lowest level ACC12 and DEC12, there were found statistically significant differences only in U17 ($p< 0.01$, d= 0.38) and U19 ($p< 0.01$, d= 0.53) categories with low and high effect size, respectively. For all other thresholds statistically very significant differences were found for all the categories ($p<0.01$). Magnitude of effect size exceed the counted thresholds by power analysis in all other thresholds except for U17 ACC34 versus DCC34 (d= 0.49) and ACC45 versus DCC45 (d=0.51).

CONCLUSION: The results confirm that more DEC than ACC occur in football matches when higher thresholds are considered. On the contrary, the opposite is true in lower speed changes. Additionally, the team category significantly impacts the results, with U17 showing significantly lower number of ACC and DEC compared to the 2nd team in all thresholds. In addition, one of the main findings for practice is, that integrating accelerations and decelerations into one variable (i.e. mean value) is not recommended for greater thresholds (>4 ms-2), where the difference between ACC a DEC is greater.

MULTIVARIATE ANALYSIS OF SET PIECES AT WOMEN AND MEN 2021-22 UEFA CHAMPIONS LEAGUE

TREJO, A., CORREA, R., TRUJILLO-BAAMEIRO, D.

UDELAR-ISEF; IUACJ

INTRODUCTION: Set pieces (SP) are widely regarded as significant technical-tactical indicators of sport performance in football (Ugalde and Rodríguez, 2021), with studies indicating they contribute significantly, up to 40%, to the overall tally of goals scored (Mitrotasios et al., 2021). While there has been a rise in research focusing on these critical moments in women´s football matches, there remains a noticeable gender disparity in the analysis of performance indicators in team sports (Adán et al., 2020). Therefore, the aim of the present study was to analyze and compare women´s and men´s offensive performance during direct and indirect free kicks (DFK; IFK) and corner kicks (CK) in the 2021-22 UEFA Champions League

METHODS: The sample was composed of 1945 CK and free kick (FK) sanctioned at female and male 2021-22 UEFA Champions League (n=61 female matches and n=61 male matches). Observational methodology procedures were followed for

collecting data. the binary regression and classification tree (Exhaustive CHAID) multivariate models were used to identify the best predictor variables for women and men.

RESULTS: Results showed that 15,8 ± 3,9 SP were registered at the women´s tournament (6,0 ± 2,8 FK; 9,8 ± 3,1 CK) and 16,1 ± 4,8 SP at the men´s tournament (7,0 ± 3,2 FK; 9,2 ± 3,3 CK) having CK a significant relationship ($p < 0.05$) with women and FK ($p<0.05$) with men. Women teams presented a significant tendency to end CK with shots on goal ($p<0.05$) reaching a 4.2% efficacy, while men saw more incomplete plays and ball possession losses ($p<0.05$) presenting an efficacy of 3.0%. Similarly, in FK situations, women tended to aim for goal and take shots outside the goal ($p<0.05$), whereas men tended to initiate organized attacks ($p<0.01$). The CHAID results identified women teams taking CK when match status is winning, and executing them with opposite foot (having an in swing trajectory). Moreover, not winning male teams registered SP while winning and executed CK with natural kick or short corner. Male teams tended to continue playing an organized attack when having a CK and match status was draw or losing.

CONCLUSION: While presenting similar frequencies of SP sanctioned women teams seemed to be more efficient than men. Men showed a tendency to use short corner and out swinger trajectory in CK.

HOW IS THE TEAMS RUNNING PERFORMANCE WHILE SCORING AND CONCEDING GOALS IN UEFA CHAMPIONS LEAGUE: ANALYSIS OF 5 MINUTES TIME-INTERVALS

CHMURA, P., MODRIC, T., DROZDZOWSKI, A.

WROCLAW UNIVERSITY OF HEALTH AND SPORT SCIENCES

INTRODUCTION: Performance analysis can provide the coach with a range of relevant information and support more informed decision-making [1]. The objective of the research was to determine the running performance (RP) according to scored and conceded goals in the UEFA Champions League (UCL) within each 5-minute time interval.

METHODS: The matches from the 2020/2021 season in the UEFA Champions League were analyzed, and relevant data were retrieved using the semi-automatic video system InStat Fitness. One-way analysis of variance (ANOVA) was used in the statistical analysis, and the effect size was determined by calculating the partial eta square ($\eta 2$). The teams performance was determined by obtaining a significant difference in total distance covered (TD) and high intensity running (HIR) under the following conditions: the team scored a goal, the team conceded a goal, and the score did not change.

RESULTS: Our main results indicate that, when teams scoring goals, the significant differenced occurred in 3 out of the 20 five-minute time intervals for the TD parameter and in 4 out of the 20 or the HIR. In the other hand, when teams conceded goals, showed significant differences 8 out of 20 tested intervals for TD and 3 out of 20 for HIR, respectively.

CONCLUSION: Currently, it is observed that the level of running performance is steadily increasing, the physical demands for teams are getting higher and higher, hence a need has arisen to update this information in different context of analysis, like changing the score line [2]. In conclusion, teams that significantly reduced their running performance in consequence conceded goals in all 5-minutes indicated intervals. A detailed match analysis in a 5-minute time interval with running performance is a valid indicator in relation to scored and conceded goals. From a practical point of view, coaches should be aware, especially in the context of the pace strategy used, that the teams running performance directly affects the score line and consequently also indirectly on the match outcome.

THE EFFECT OF 24 H ENERGY AVAILABILITY MANIPULATIONS BY DIET OR EXERCISE ON SUBSTRATE UTILISATION, METABOLISM, AND PERFORMANCE IN CYCLISTS

SMITH, E., KUIKMAN, M., WEAKLEY, J., TEE, N., MCCORMICK, R., ACKERMAN, K., ELLIOTT-SALE, K., STELLINGWERFF, T., HARRIS, R., MCKAY, A., BURKE, L.

AUSTRALIAN CATHOLIC UNIVERSITY

INTRODUCTION: Athletes often implement acute, adaptable, periods of low energy availability (EA) to facilitate performance goals, such as reducing body mass to meet weigh-in targets, altering body composition for competition, or intensified training blocks with increased exercise energy expenditure (EEE). Prolonged low EA is problematic, as it is associated with negative health and performance outcomes. Yet the time course for maladaptations to occur once adequate EA "thresholds" are consistently unmet remains unclear. The method of reducing EA (i.e., dietary restriction or increased EEE) may also influence physiological outcomes. This is relevant in tailoring athlete training/nutritional protocols to alter body composition whilst minimising negative consequences. Additionally, there is some evidence that women may be more sensitive to the physiological effects of acute low EA than men. However, studies examining sex differences are scarce, particularly among trained athletes. We therefore examined how 24 h EA manipulations, induced by diet or exercise, influenced next day substrate oxidation, postprandial metabolism, and performance among trained women and men.

METHODS: In a Latin Square design, 20 endurance athletes (10 females using monophasic oral contraceptives and 10 males) undertook five trials, each comprising three consecutive days. Day one was a standardised period of high EA; EA was manipulated on day two; and post-intervention testing occurred on day three. EA on day two was low/high/higher EA (LEA/HEA/GEA) at 15/45/75 kcal·kg·FFM·day-1, respectively. Participants received prescribed food and drink prepackaged and weighed before each trial. Conditions of LEA/HEA were separately achieved by manipulations of EEE/energy intake (LEA/HEA[REST/EX]). On day three, fasted peak fat oxidation during cycling and two-hour postprandial metabolism (high carbohydrate/energy meal) were assessed, alongside performance tests: Wingate, countermovement jump (CMJ), squat jump (SJ), isometric mid-thigh pull (IMTP), and the Stroop Colour and Word Test.

RESULTS: Highest peak fat oxidation occurred under LEA induced by exercise ($p<0.01$), with no difference between sexes. Postprandial glucose ($p<0.01$) and insulin ($p<0.05$) responses were highest across both sexes when LEA was induced by diet. Relative peak/mean power throughout the Wingate and CMJ/SJ jump height was greater in males than females ($p<0.01$), but there was no difference between EA conditions for the Wingate/CMJ ($p>0.05$). During the SJ, jump height was lower under GEA than LEAREST ($p=0.045$) and HEAEX ($p=0.023$) across both sexes. IMTP peak force and the Stroop effect did not change with altered EA.

CONCLUSION: Acute (24 h) exercise-induced manipulations in EA influence fasted substrate oxidation more than LEA induced by diet alone, while 24 hours of LEA appeared not to impair strength/power, sprint capacity, or cognitive performance, at least when measured post-prandially. Finally, the responses to EA manipulations did not differ between sexes.

POST-EXERCISE MYOFIBRILLAR PROTEIN SYNTHESIS RATES ARE EQUIVALENT FOLLOWING INGESTION OF GRADED DOSES OF LEUCINE AND ACROSS DIFFERENT MENSTRUAL CYCLE PHASES IN YOUNG FEMALES

APICELLA, M., JAMESON, T., ABDELRAHMAN, D., MURTON, A., ALAMDARI, N., DIRKS, M., WALL, B., STEPHENS, F.

UNIVERSITY OF EXETER

INTRODUCTION: Optimal adaptation to resistance exercise likely requires a maximal rate of myofibrillar protein synthesis (MyoPS), which is thought to be achieved by the post exercise consumption of >20g of protein or ~2g of the essential amino acid (EAA) leucine. Recent work has challenged this centrality of leucine and suggested that such responses may also vary in females due to typically lower body mass and differing hormonal profiles. However, limited data is available on the role of naturally fluctuating oestrogen (O) concentrations during the menstrual cycle (MC) in regulating postprandial post-exercise MyoPS. This study aims to investigate the effect of post-exercise ingestion of low and moderate compared to an optimal dose of leucine on MyoPS, and determine if post-exercise MyoPS and expression of 46 genes involved in the regulation of muscle mass are different during the early follicular (EF, low O) and late follicular (LF, high O) phases of the MC, when progesterone (Pg) is low.

METHODS: Twenty-eight healthy, eumenorrheic females (age: 27±8 y; BMI: 24±3 kg/m2) completed one of three parallel experimental trials in a randomised double-blind manner during EF (4±1d following menses; O 183±78 pmol/l, Pg 1.1±0.7 nmol/l). A subset of 17 participants completed a second trial during LF (2±2 d before luteinising hormone surge; O 855±571 pmol/l, Pg 4.0±5.1 nmol/l), in a randomised order. On each visit, participants received a primed continuous infusion of L-[ring-2H5]phenylalanine for 7.5h. Following a bout of resistance exercise, participants ingested one of three drinks containing 1.5g EAA (n=10) or 15g (n=10) and 20g (n=8) whey protein, equating to 0.6, 1.5, and 2.0g leucine, respectively. Muscle biopsies were collected before and during the 4h post-exercise postprandial period to assess MyoPS and

gene expression. Two-way ANOVAs were performed to detect changes across drinks and MC phases. Data are expressed as means±SD.

RESULTS: Post-exercise drink ingestion increased MyoPS above postabsorptive values after 2h by 0.058±0.038, 0.035±0.050 and 0.064±0.036%·h-1 (P<0.0001) and after 2-4h by 0.050±0.035, 0.011±0.040, and 0.031±0.063%·h-1 (P=0.009) for 0.6g, 1.5g, and 2.0g drinks, respectively, with no interactions observed. MyoPS increased by 0.050±0.056 and 0.048±0.081%·h-1 after 2h (P<0.001), but not 2-4h (P=0.522) for EF and LF, respectively, with no differences between MC phase at either timepoint. Muscle mRNA expression of several genes involved in oestrogen signalling, protein synthesis, and inflammation were increased in LF vs EF, and to a greater extent 4h post-exercise, whereas protein breakdown genes were decreased.

CONCLUSION: Ingestion of 0.6g (1.5g EAA) or 1.5g leucine (15g protein) increases post-exercise MyoPS to a comparable extent as 2g leucine (20g protein) in females. This increase in MyoPS does not appear to be affected by increased O during the LF phase of the MC, despite a gene expression profile in LF consistent with muscle growth.

EFFECT OF PRE-SLEEP ALPHA-LACTALBUMIN SUPPLEMENTATION IN AN ATHLETICALLY TRAINED POPULATION WITH SLEEP DIFFICULTIES

BARNARD, J., ROBERTS, S., LASTELLA, M., CALLAHAN, D., AISBETT, B., CONDO, D.

DEAKIN UNIVERSITY

INTRODUCTION: Sleep is vital for optimal recovery and sporting performance (1). Recently, protein has been identified as a dietary factor influencing the sleep of athletically trained populations (2), whereby the type and timing of protein appears crucial in the protein-sleep relationship (3). Evening consumption of a whey protein rich in the amino acid tryptophan (TRP), alpha-lactalbumin (ALAC), has previously shown to benefit sleep - particularly among poor sleepers (4). Given trained populations often experience sleep difficulty (5), this study sought to investigate whether acute evening supplementation of ALAC would influence sleep outcomes, and next-day cognitive performance within a trained population with sleep difficulties.

METHODS: Nineteen trained males (n=8) and females (n=11) with sleep difficulties aged 18-40 completed this double-blinded, counterbalanced, randomised, cross-over trial. 40 g ALAC (1.9 g TRP) or an isocaloric placebo (collagen) were supplemented two hours prior to individualised bedtime for three consecutive nights in a controlled environment, with sleep measured using portable electroencephalography (DREEM 3). Diet was standardised to 1.2 g/kg body weight protein throughout the day, with a low-protein dinner provided two hours prior to the supplement to limit confounding effects on TRP levels. On the first night of each intervention period, blood samples were taken across five evening timepoints (0, 30, 60, 90, 120 min post-supplement) prior to bedtime. A tablet-based testing battery (Joggle Research) assessing multiple cognitive domains was completed next day, thirty minutes after waking. Mixed models were used to assess the effect of treatment on sleep variables and cognition, with time added as a fixed effect to determine the treatment and time interaction for plasma TRP concentrations.

RESULTS: During the ALAC condition, participants had an increased NREM stage 2 sleep duration (PLA 205.9 ± 33.3, ALAC 216.5 ± 33.1 min); improved reaction time in cognitive tests involving sensory motor speed, spatial orientation, and vigilant attention ($p<0.05$); and raised plasma TRP across all timepoints compared to 0 min ($p<0.01$). No other sleep or cognitive outcomes were affected by ALAC supplementation.

CONCLUSION: Pre-sleep ALAC supplementation increased NREM stage 2 sleep, improved morning cognition, and augmented plasma TRP levels compared to placebo. With NREM stage 2 sleep being important for brain plasticity and motor learning (6, 7), acute supplementation of ALAC may prove beneficial to trained individuals with sleep difficulties looking to assist next-day performance. Future research should investigate the impact of chronic ALAC supplementation on sleep and next-day sporting performance within a trained population with sleep difficulties.

EXERCISE-INDUCED HYPOHYDRATION IMPAIRS ENDURANCE RUNNING PERFORMANCE IN THE HEAT IN FEMALE, BUT NOT MALE, RUNNERS: EVIDENCE OF A SEX-HYDRATION INTERACTION

CABLE, T., FUNNELL, M., PEDEN, D., REYNOLDS, K., TAYLOR, L., MEARS, S., JAMES, L.

LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Exercise-induced hypohydration impairs endurance performance in the heat, but most data is in cycling, with less known about running. Furthermore, the impact of biological sex on physiological and performance responses to hypohydration is unclear. Females have a smaller relative total body water (TBW) compared to males, and thus symptoms of hypohydration may be exacerbated in females. Therefore, this study assessed the impact of exercise-induced hypohydration on running performance in the heat in male and female runners.

METHODS: 11 male (M; age 37 ± 3 y; VO2peak 61 ± 3 mL/kg/min) and 8 female (F; age 34 ± 4 y; VO2peak 54 ± 4 mL/kg/min) trained runners completed a familiarisation (ad-libitum water intake) and two experimental trials, involving a preload (PL; 7 x 10 min at 60% VO2peak, 1 min rest) and a 3 km time-trial (TT) on a treadmill in the heat (32°C, 50% RH). Water to replace sweat loss (EU) or a total of 80 mL water (HH) was provided during the PL to manipulate hydration, aim-

ing for ~3% reduction in TBW in HH. TBW was estimated by bioelectrical impedance and used to compare relative TBW loss between sexes. Venous blood was collected, and nude body mass measured at baseline, post-PL and post-TT, with gastrointestinal (GI)/skin temperature, heart rate, perceptual responses and oxygen uptake measured throughout trials. 3 km TT performance was the primary outcome.

RESULTS: Post-PL relative TBW loss in EU (M -0.6 ± 0.2%; F -0.7 ± 0.3%) and HH (M -3.5 ± 0.6%; F -3.1 ± 0.4%) was not different between sexes (P≥0.109). Hypohydration increased heart rate, GI temperature and thirst, and decreased body mass and plasma volume (P≤0.041), but did not alter skin temperature, oxygen uptake, RPE, GI comfort or thermal sensation (P≥0.380). However, there were no trial*time*sex interactions for any physiological or perceptual variable (P≥0.108). There was a trial*sex interaction for 3 km TT performance (P=0.034), with females 5% slower in HH (EU 970 ± 286 s; HH 1020 ± 316 s; P=0.037), with no significant difference between trials in males (EU 715 ± 52 s; HH 722 ± 55 s; P=0.405). During familiarisation, ad-libitum water intake in PL replaced more of the sweat loss in females (M 47 ± 26%; F 67 ± 28%; P<0.001), meaning relative TBW loss was less in females (M 3.3 ± 1.3%; F 2.4 ± 1.4%; P<0.001).

CONCLUSION: These data demonstrate that hypohydration impairs endurance performance in female, but not male, runners, but sex did not significantly alter any physiological or perceptual variables. Interestingly, during familiarisation, ad-libitum water intake replaced a greater proportion of sweat losses in females, producing a lower relative TBW deficit. This indicates some sex-based differences in hydration behaviour that might explain some of the observed performance effects of hypohydration. These results suggest that where high sweat rates are likely during running, females might need to pay more attention to hydration strategies than males.

GLYCEROL-AND SODIUM-INDUCED HYPERHYDRATION DOES NOT IMPROVE HALF-MARATHON TIME-TRIAL PERFORMANCE IN TRAINED RUNNERS IN WARM CONDITIONS.

JARDINE, W., CONDO, D.1, AISBETT, B.1, ROSS, M.L.2, BURKE, L.M.2, DURKALEC-MICHALSKI, K.3, PÉRIARD, J.D.4, CARR, A.J.1

1 DEAKIN UNIVERSITY, AUSTRALIA; 2 AUSTRALIAN CATHOLIC UNIVERSITY, AUSTRALIA; 3 POZNAN UNIVERSITY OF PHYSICAL EDUCATION, POLAND; 4 UNIVERSITY OF CANBERRA, AUSTRALIA

INTRODUCTION: Hyperhydration aims to offset fluid loss during endurance exercise in hot conditions and is achieved by ingesting large volumes of fluid with an osmolyte (i.e., glycerol or sodium) to enhance fluid retention. The aim of this study was to investigate the effect of combined glycerol- and sodium-induced hyperhydration (HYP), compared to a control (CON), on 1) half-marathon time-trial performance and 2) hydration measures (fluid retention, plasma volume; PV), core temperature (Tcore) and heart rate (HR) in the field.

METHODS: Endurance-trained athletes (n = 13, 1 F, age: 33 ± 7 yr, height: 1.78 ± 0.07 m, weight: 72 ± 10 kg, VO2max: 60.07 ± 8.39 mL/kg/min) completed two half-marathon time-trials in outdoor conditions (wet-bulb globe temperature: HYP: 23.5 ± 1.8°C, CON: 23.7 ± 2.7°C). Before each time-trial, participants completed either a 180-min HYP (25 mL/kg BM of fluid with 1.2 g/kg BM of glycerol and 7.5 g/L of sodium chloride in four equal aliquots, finishing 120 min pre-exercise) or CON (volume-matched beverage ingested at the same time points). Urine volume (UVol) was recorded every 20 min pre-exercise and fluid retention was calculated as fluid ingested minus UVol. Capillary blood samples were taken at baseline and every 60 min pre-exercise for haematocrit and haemoglobin to assess for changes in PV. During each time-trial, Tcore and HR were recorded. Linear mixed modelling was used to determine interaction effects between conditions for fluid retention, changes in PV, Tcore, HR and exercise performance. Results are reported as mean differences and 95% confidence intervals (lower bound, upper bound).

RESULTS: There were no differences between conditions for exercise performance (HYP: 101.51 ± 18.45 min, CON: 101.74 ± 16.97 min; p = 0.960). There was greater fluid retention in HYP compared to CON at 80 min (234 mL (32, 436); p = 0.024), 100 min (470 mL (268, 672); p < 0.001), 120 min (769 mL (567, 971); p < 0.001), 140 min (870 mL (668, 1072); p < 0.001), 160 min (996 mL (794, 1198); p < 0.001) and 180 min (1189 mL (987, 1391); p < 0.001). Changes in PV were greater in HYP, than CON, at 60 min (9.1% (4.8, 13.4); p = 0.014), 120 min (11.6% (7.3, 15.9); p = <0.001) and 180 min post-ingestion (11.7%, (7.4, 15.9); p = 0.001) and post-exercise (6.9% (2.6, 11.1); p < 0.001). There were no differences in mean Tcore (p = 0.44), peak Tcore (p = 0.88) or mean HR (p = 0.55).

CONCLUSION: The findings from this study indicate that the combined ingestion of glycerol and sodium significantly enhanced fluid retention and PV compared to a matched fluid volume. However, these differences in hydration status did not provide a thermal-, cardiovascular- or performance-benefit to trained runners during a simulated half-marathon time-trial in the field, potentially due to the relatively low environmental stimulus used in this study. Future work may consider a stronger environmental stimulus when assessing differences in exercise performance.

OP-MH06 Exercise and cancer I

THE INCLUSION OF CHILDREN WITH CANCER IN AN ADAPTED FOOTBALL TRAINING PROGRAMME IN HOSPITAL

GUARESCHI, S., REDAELLI, R., CALDARA, E., MORIGGI, T., VILLA, E., ZARDO, W., CORTI, E., PELI, L., CORTI, M., JANKOVICH, M., BALDUZZI, A., MORATTI, C., LANFRANCONI, F.
INTER CAMPUS MILANO

INTRODUCTION: Cancer is the leading cause of death among children over the age of one in Europe, and more than 15,000 children and adolescents are diagnosed with cancer each year in Europe. Up to 80% of them can be cured with standard multidisciplinary care. Children, adolescents and young adults with cancer (CAYA-c) suffer from acute and chronic disabilities. Precision-based exercise programmes and sports are a new therapeutic option to counteract the side effects of cancer treatment in hospital. Inter Campus uses the values of football as an educational tool and contributes to the development of local communities by supporting educational, social and health programmes and promotes social integration between different ethnic groups and cultures. The aim of this study was to test the effectiveness of implementing the Inter Campus method in a complex clinical setting.

METHODS: CAYA-c participating in a precision training research programme from 1 September to 31 December 2023 were enrolled. They were referred to the programme by their oncologists. Both sexes, aged between 3 and 21 years, with a diagnosis of blood cancer in the previous 8 weeks were eligible. Between the 3 weekly sessions of combined training (cardiorespiratory, resistance, flexibility and balance), 1 session of football was provided by Inter Campus. The methodology is based on a global approach to football training that includes performance, but also cognitive, emotional-affective and social areas of the childrens and adolescents personalities. Each child received exercises tailored to their own resources and vulnerabilities. Football sessions have been offered on the wards, including the bone marrow transplant center. When followed up in the outpatient clinic, they were trained in small groups (3 to 9 CAYA-c) in the gym, including an outdoor area, in the hospital. The frailest were trained with other CAYA-c to emphasize the inclusion part of the project.

RESULTS: A total of 31 consecutive CAYA-c were enrolled and 29 were trained. The average age was 11.3 ± 5.9 years (range 4-20), 44.8% were female. The diagnoses were acute lymphoblastic and myeloid leukemias (60% and 16%), lymphoma (24%). Adherence to training (number of sessions/expected sessions) was 33% (range 7-80%). CAYA-c satisfaction with the intervention was 9.2 out of 10 in general and 8.8 for Inter Campus activities; parents reported 9.8 and 9.1, respectively. There were no major events related to football activities.

CONCLUSION: Close consultation between pediatricians and exercise professionals, including football coaches with a pedagogical profile, is essential when introducing sport in hospitals. The use of football could be safe even in complex clinical settings. Adherence to training can be low for the most medically fragile children, although their willingness to participate in sports activities remains throughout their care. The satisfaction of the families and of CAYA-c is high and the resulting impact on their inclusion could be enormous.

NEAR INFRARED SPECTROSCOPY IN SKELETAL MUSCLE OXIDATIVE EVALUATION IN CHILDREN WITH BLOOD CANCER IN HOSPITAL.

ZARDO, W., MORIGGI, T., VILLA, E., CORTI, E., PELI, L., BALDUZZI, A., LANFRANCONI, F.
FONDAZIONE MONZA E BRIANZA PER IL BAMBINO E LA SUA MAMMA

INTRODUCTION: Cancer is the leading cause of death from non-communicable diseases in children, adolescents and young adults with cancer (CAYA-C) in Europe. Reduced exercise capacity in CAYA-C may reflect both bed rest and drug-induced side effects such as cardiopulmonary dysfunction and/or reduced skeletal muscle oxidative metabolism due to myopathy and peripheral nervous system impairment. The individuals reduced exercise capacity in complex clinical situations, i.e. during the intensive phases of CAYA-C treatment, can be assessed by cardiopulmonary exercise testing (CPET). During CPET, near-infrared spectroscopy (NIRS) measures muscle oxidative capacity in vivo at the vastus lateralis and physiological calibration using an ischaemic leg cuff manoeuvre is required to compare different individuals. The leg cuff maneuver is not an option in CAYA-C with cancer due to severe thrombocythemia. The aim of this pilot study was to test whether adapted NIRS physiological calibrations obtained by quadriceps isometric and isotonic exercise manoeuvres can be performed in CAYA-C instead of the classical leg-cuff ischaemia.

METHODS: After CPET on a cyclergometer, ischaemia of the quadriceps was performed on 3 CAYA-C with blood cancer (age 16.0±3.0 years) by means of isometric and isotonic exercises on a leg extension machine (80% of 1 maximum repetition). Each manoeuvre was separated by 2 minutes of rest and the difference between the values at rest and at the end of the manoeuvres was calculated, until a plateau of deoxygenated hemoglobin values was reached (D[HHb], A.U.). In 3 healthy young adults (HEAL) the 2 methods were compared with a 300 mmHg leg cuff tourniquet and the D[HHb] kinetic time (τ, sec) was measured. The D[HHb] values obtained during CPET were expressed as a percentage of the different ischaemias (D[HHb]/D[HHb]isch).

RESULTS: None of the CAYA-C patients complained of pain during the manoeuvres, although the HEAL patients experienced discomfort during the leg-cuff. The 3 CAYA-C showed D[HHb] 19.1±2.8 and 16.8±2.7 in relation to isometric and isotonic conditions respectively, without any statistical difference. The D[HHb]/D[HHb]isch were 0.38±0.08 and 0.34±0.07 in relation to isometric and isotonic conditions, respectively. The 3 HEAL showed D[HHb] 10,1±6,5, 9,3±9,8 and 11,7±9,0 in relation to isometric, isotonic and leg cuff conditions respectively without any statistical difference. The τ of the 3 procedures were 36,8±21,0, 23,1±22,9 and 249,8±133,7 respectively with a significant statistical difference (p<0,006)

CONCLUSION: The adapted physiological NIRS calibrations were well tolerated in both CAYA-C and HEAL. Reduced oxidative metabolism was observed in CAYA-C and comparable D[HHb] values were found between isometric and isotonic manoeuvres. HEAL showed that the kinetics of the leg cuff is slower than other manoeuvres and give reasons for the pain experienced during the manoeuvres, adding concern in performing the manoeuvre in CAYA-C.

CHANGES IN PEAK OXYGEN CONSUMPTION ELICITED BY PREHABILITATION PRIOR TO ONCOLOGIC RESECTION

LAZA CAGIGAS, R., RAMPAL, T., LARUMBE-ZABALA, E., SEIJO, M., NACLERIO, F.
UNIVERSITY OF GREENWICH

INTRODUCTION: Cardiopulmonary exercise testing is frequently utilised in the United Kingdom to assess patients' functional capacity prior to elective surgery. Both peak oxygen (VO2Peak) and the amount of oxygen consumed at the 1st ventilatory threshold have been used as markers of functional capacity with low values linked to morbidity and mortality in the postoperative period. Surgical prehabilitation (PREHAB) is an intervention including one or more lifestyle components (e.g., exercise) implemented to enhance functional capacity in patients awaiting surgery.

We aimed to systematically summarize the effects of PREHAB on VO2Peak in patients awaiting oncologic resection.

METHODS: This systematic review was conducted in accordance with the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISMA) checklist and registered with the International Prospective Register of Systematic Reviews, PROSPERO (CRD42023428676). The search of the literature was conducted using Cochrane Library, EBSCOhost, Google Scholar, MEDLINE PubMed, and Web of Science from March 2023 to October 2023. Inclusion criteria were randomized controlled trials (RCT), including adult patients (≥18 years old), diagnosed with any type of cancer, who could be undergoing or not neo-adjuvant chemotherapy, implementing any type of PREHAB modality (i.e., unimodal or multimodal), delivered at any venue (i.e., home, hospital or in the community), by any means (i.e., telehealth or face-to-face) and including at least an intervention group (PREHAB) and one control group (standard care). Continuous data on VO2Peak as a marker of functional capacity were pooled using a random-effects model. The Comprehensive Meta-Analysis Software, v. 4.0.000 (Biostat Inc., Englewood, New York, USA) was used for the analysis.

RESULTS: Seven RCTs reporting VO2Peak met the inclusion criteria. The overall quality of the included studies was high, with a low risk of bias, scoring from 2 to 5 points in the Cochrane collaboration tool. All the studies included an exercise component. Two studies implemented multimodal prehabilitation and five implemented unimodal exercise-based prehabilitation. The mean effect size (Hedges' g) of PREHAB vs. standard care on VO2Peak was medium (n = 7, g= 0.615, 95% CI 0.243 to 0.987), and statistically significant (Z = 3.240, p = 0.001). The prediction interval was calculated from -0.562 to 1.793 (95% CI). The sensitivity analysis showed that none of the studies contributed disproportionately to the results of the meta-analysis and no outliers were identified amongst the analysed studies.

CONCLUSION: Considering the overall findings and the estimated prediction interval from the seven meta-analysed RCTs, we are unable to support the claim that PREHAB improves VO2Peak.

THE PECTORALIS MAJOR STRETCH RESPONSE IN WOMEN AFTER RADIOTHERAPY FOR BREAST CANCER

WOLFRAM, S., LIPPS, D.B.
UNIVERSITY OF MICHIGAN

INTRODUCTION: Radiotherapy (RT) for breast cancer has been associated with shoulder co-morbidities like reduced strength and range of motion (ROM) (1). These impairments may be related to stiffening of shoulder muscles, like the pectoralis major, after RT (2). Increased pectoralis major muscle stiffness likely causes difficulties with shoulder abduction. However, it is unknown how this muscle responds to stretch during this movement. The purpose of this study was to examine the passive stretch response of the pectoralis major during shoulder abduction after RT for breast cancer.

METHODS: The sternocostal region of the pectoralis major was examined in 18 breast cancer survivors 12-60 months after completing RT (mean ± SD age 57.4 years, height 163.6 ± 7.1 cm, 77.3 ± 10.2 kg) and 18 age-matched cancer-free controls (age 59.3 ± 9.1, height 163.4 ± 6.0 cm, 60.7 ± 10.4 kg). Ultrasound shear wave elastography images were obtained in increments of 5° shoulder abduction as participants remained relaxed. Shear wave velocities (SWV) were extracted from these images as a measure of muscle stiffness. Slack angle, SWV at slack (SWV0) and elasticity coefficient were determined from a piece-wise exponential model fitted to the SWV-joint angle curve (3). Differences between the groups for these parameters were examined with an independent two-sided t-test. Joint angles were normalised to 100%ROM, starting at the slack angle. SWVs were extracted for joint angles at intervals of 10%ROM using non-linear interpolation. A repeated-measures ANOVA tested if SWVs differed between the two groups (between-subjects factor) and joint angles (within-subjects factor).

RESULTS: Slack angle was similar (p = 0.84) between groups (breast cancer group: 49.4 ± 16.0°; control group: 50.7± 20.5°). SWV0 was significantly greater (p = 0.016) for the breast cancer group (2.41 ± 0.46 m/s) than the control group (2.1 ± 0.26 m/s). There was no difference (p = 0.36) in the elasticity coefficient between the breast cancer (0.0073 ± 0.0026)

and the control group (0.0065 ± 0.002). SWVs increased significantly with an increase in joint angle from slack angle onwards for both groups ($p < 0.001$), with greater SWVs for the breast cancer group than the control group ($p = 0.02$).

CONCLUSION: Higher SWVs in the breast cancer group throughout the examined abduction ROM indicate increased stiffness of the pectoralis major after RT for breast cancer, which is likely due to radiation-induced muscle fibrosis. However, slack angle and elasticity coefficient did not differ between groups suggesting that the stretch response of the pectoralis major is not altered. Therefore, higher pectoralis major muscle stiffness after RT may not contribute to limitations in abduction ROM commonly observed in breast cancer survivors.

NEAR-INFRARED SPECTROSCOPY MUSCLE REOXYGENATION KINETICS ARE SLOWED WITH INCREASING EXERCISE INTENSITY IN AN INCREMENTAL CYCLING TEST: COMPARISON BETWEEN MUSCLE SITES

JEM, A., YOGEV, A., NELSON, H., KOEHLE, M.S.

UNIVERSITY OF BRITISH COLUMBIA

INTRODUCTION: Near-infrared spectroscopy (NIRS) is used to indicate the balance of local oxygen (O2) delivery and O2 uptake in exercising muscle. Muscle oxygen saturation (SmO2) generally decreases proportionally to exercise intensity and duration, and increases during recovery. Reoxygenation represents a relative excess in O2 delivery during recovery while O2 uptake declines as the local metabolic milieu is restored. Reoxygenation is typically evaluated in a single working muscle, where SmO2 will reach peak values above resting baseline (hyperaemia) within 1-3 minutes after maximal exercise. We sought to compare reoxygenation kinetics between working and accessory muscles during an incremental cycling exercise step test (IET) as a function of increasing intensity. We hypothesised that reoxygenation would be faster in working muscle, slower in accessory muscle, and slower overall with increasing intensity.

METHODS: Twenty-one trained cyclists (10 F, 11 M) performed two IET trials at 1.0+0.5 W·kg-1 per 5-min stage, with 1 min rest between stages, to maximal tolerance. Moxy NIRS sensors (Fortiori Design LLC, Hutchinson, MN, USA) were placed on vastus lateralis (VL), rectus femoris (RF), erector spinae (ES), and deltoid (DL) muscles. Reoxygenation kinetics were evaluated during rest intervals as the time to recover half the SmO2 amplitude from the end of work to the peak SmO2 value (half recovery time, HRT in seconds). A linear mixed effects model was used to analyse HRT with fixed effects for trial, relative intensity (% peak workload), and muscle site, with random effects of slope and intercept by participant. Post hoc estimated marginal means were contrasted across intensity at 50%, 75%, and 100%, and between muscle sites.

RESULTS: Reoxygenation kinetics were generally slower (HRT was greater) with increasing exercise intensity beyond 50% in the VL, RF, and ES muscles (each $p<0.01$), but not DL ($p>0.05$). VL had the lowest between- and within-participant variation and recovered faster than other sites (HRT model estimates [95% CI]: VL=9 [6, 11], 12 [9, 14], 17 [13, 21] sec at 50, 75, 100% intensity, respectively). RF, ES, and DL were progressively slower at all intensities ($p<0.001$), except for ES and DL at 100% (ES=38 [34, 42] vs DL=40 [36, 45] sec; contrast=3 [-3, 9] sec, $p=0.68$).

CONCLUSION: In a cycling IET, reoxygenation kinetics are faster in working muscle than accessory muscle, and generally slower overall as systemic metabolic demands increase with intensity. The VL is the primary working muscle in cycling and is consistently prioritised for recovery, as might be expected where motor recruitment and metabolic demand are highest. Slower recovery and higher variability in other muscle sites hint at heterogeneities in accessory muscle recruitment strategies and systemic competition for cardiac output. Integrating NIRS responses across working and accessory muscles may help to reveal more about local contributions and limitations to performance.

MAXIMUM END-EXPIRATORY BREATH-HOLDS DURING REPEATED SPRINT TRAINING: IS IT EFFECTIVE?

RABERIN, A., CARLETTA, M., FRANCHI, N., CITHERLET, T., MANFERDELLI, G., MILLET, G.P.

UNIVERSITÉ DE LAUSANNE: UNIVERSITE DE LAUSANNE

INTRODUCTION: Repeated sprint training in hypoxia (RSH) was shown as an effective method for enhancing repeated sprint ability. Since the required hypoxic device is not always available throughout a season or for each athlete, an alternative method called repeated sprint training with hypoventilation at low lung volume (RSH-VHL) was developed to induce a hypoxic stress. However, it also generates acidosis and hypercapnia. Recently, the concept of exercising with bouts of end-expiratory breath-hold until the voluntary breaking point (UBP) has been proposed, offering an even more hypoxemic and hypercapnic stimulus during high-intensity interval training, although this has not been applied specifically to repeated-sprints training.

Therefore, the objective of this study was to compare the physiological responses of repeated sprint training in normoxia (RSN), RSH-VHL, and repeated sprint training during end-expiratory breath-hold until the breaking point (RSH-UBP). Due to putative higher hypoxic and hypercapnic stress, we hypothesized a greater amplitude in stroke volume changes and muscle deoxygenation/reoxygenation (i.e., Tissue Saturation Index, TSI) during RSH-UBP compared to RSH.

METHODS: Ten healthy active men performed 3 sessions of sprint training (2 sets of 8 sprints with 5 min of rest between sets; exercise:rest ratio of 1:2) in a randomized order. Sprint duration was 10 s for RSN and RSH-VHL conditions, while it depended on the apnea duration for RSH-UBP. Pulse oxygen saturation (SpO2), gas exchange, cardiac hemodynamics, muscle oxygenation, and total work were continuously recorded during the sessions.

RESULTS: The time spent <96% of SpO2 (all $p<0.010$) and mean end tidal carbon dioxide pressure (all $p<0.001$) during the exercise bouts were higher in both RSH-VHL (81±65 s and 33.6±4.2 mmHg) and RSH-UBP (74±57 s and 32.9±3.5 mmHg) than in RSN (11±14 s and 27.8±4.2 mmHg). The pH similarly decreased from pre- to post-session between sprint modalities ($p=0.137$). Total work was lower ($p<0.001$) during RSH-UBP (33.1±5.8 kJ) compared to RSH-VHL (46.5±5.7 kJ) or RSN (47.4±6.0 kJ). Stroke volume and cardiac output did not differ between sprint modalities (all $p>0.4$). Amplitude in TSI changes was smaller ($p<0.050$) during RSH-UBP (7.0±4.3%) compared to RSH-VHL (10.3±6.0%) but not compared to RSN (10.3±7.1%).

CONCLUSION: While RSH-UBP induced a greater hypoxic and hypercapnic stress than RSN, no difference was observed when compared to RSH-VHL. The reduction in total work during RSH-UBP was attributed to participants inability to maintain long-enough apnea, leading to a decrease in sprint duration. Consequently, the muscle deoxygenation level during RSH-UBP appeared blunted.

In conclusion, acutely, RSH-VHL appeared as a more effective condition than RSH-UBP. Further interventional training studies comparing the two strategies are required to assess if RSH-VLH can better preserve training load and elicit consistent physiological adaptations.

ACUTE MOUNTAIN SICKNESS PREDICTION USING NOCTURNAL OXYGEN SATURATION-RELATED METRICS IN PREMATURELY-BORN HEALTHY ADULTS

NARANG, B., MANFERDELLI, G., MILLET, G., DEBEVEC, T.

JOŽEF STEFAN INSTITUTE

INTRODUCTION: Specific responses to hypoxia at rest and during exercise have been observed in healthy adults born preterm [1]. Nocturnal pulse oxygen saturation (SpO2) recordings, together with acute mountain sickness (AMS) assessment, could offer insights into the aetiology of prematurity-related altitude (in)tolerance.

METHODS: In this study, 12 pre-term (Mean±SD; age: 21±3 yr, BMI: 23±3 kg/m^2, gestational age: 29±2 wk) and 12 term-born (22±3 yr, 23±2 kg/m^2, 40±1 wk) male adults underwent an overnight normobaric hypoxic exposure equivalent to 4200 m. AMS was assessed using the Lake Louise scale 6 h after hypoxic room entry (9pm), and the following morning 1 h after waking (7am). Participants were classified as AMS+ if their total symptom score was ≥3, with a headache score ≥1 [2]. SpO2 was recorded continuously at 3 Hz at the fingertip. Data from 11pm to 5am were extracted, and mean SpO2 and proportion of the 6 h with SpO2<80% (TST80) were calculated. Desaturations were defined by rate (>0.1%/s), magnitude (≥2%), and total duration until re-saturation (≥10 s & ≤60 s) [2]. The cumulative desaturation areas above the curve, relative to each respective onset value, indicated the hypoxic burden (%min/h). Groups were compared using independent t-tests and Mann-Whitney U tests, and are reported as Mean±SD and Median[IQR], respectively. Receiver operating characteristic (ROC) analysis was used to indicate the predictive potential of SpO2 metrics for morning AMS incidence. The area under the ROC curve (AUC) is reported, representing the balance between true- and false-positive AMS classifications.

RESULTS: Before sleep, 9 term-born and 7 pre-term participants were AMS+. Upon waking, 5 term-born and 6 pre-term participants were AMS+. Nocturnal mean SpO2 was similar between the pre-term and term-born groups (77±3 vs 77±4%; $p=0.661$), as was TST80 (72±29 vs 70±27%; $p=0.879$). However, mean SpO2 and TST80 predicted morning AMS considerably better in the pre-term (AUC=0.889 and 0.944, respectively) than in term-born (AUC=0.457 and 0.571, respectively) participants. Pre-term adults experienced more desaturations (413[291] vs 122[209]; $p=0.008$), albeit shorter in average duration (17±2 vs 21±2 s; $p<0.001$). Pre-term participants also experienced a significantly greater hypoxic burden (32[26] vs. 7[25] %min/h; $p=0.039$). However, desaturation-related metrics did not predict morning AMS incidence accurately in the two groups separately or combined (all AUC<0.743).

CONCLUSION: These data indicate high predictive potential of composite nocturnal SpO2 metrics for AMS incidence in healthy adults born pre-term. However, while desaturations were more frequent in pre-term adults, inducing a greater hypoxic burden, they were neither predictive of AMS-related outcomes in pre-term participants, nor in their term-born counterparts.

CONTROLLED MODERATE HYPOXIA ACUTELY PREVENTS PHYSICAL INACTIVITY-INDUCED PERIPHERAL BDNF DECLINE

DUDERSTADT, Y., SCHREIBER, S., BURTSCHER, J., SCHEGA, L., MUELLER, N.G., BRIGADSKI, T., BRAUN-DULLAEUS, R., LESSMAN, V., MUELLER, P.
UNIVERSITY HOSPITAL MAGDEBURG

INTRODUCTION: Brain-derived neurotrophic factor [BDNF] is a crucial mediator of cognitive abilities, like long-term memory. Previous investigations indicate that different factors (e.g., physical activity, nutrition, psychosocial stress, hypoxia) can influence blood BDNF levels in humans. Currently, there is inconsistency in the reported results concerning the effects of controlled and moderate normobaric hypoxia [NH] on BDNF. Therefore, we investigated the impact of passive exposure to NH on BDNF levels in blood serum and plasma, alongside its effects on cognitive functions.

METHODS: In a controlled crossover study 25 healthy adults (25.8±3.3yrs., 15 female) were randomly exposed to normoxia [NOR] and NH (80-85 % peripheral oxygen saturation [SpO2]). The experiment started with a passive 30-min supine rest under normoxic conditions followed by a 90 min continuation of passive NOR or NH. Serum and plasma blood samples were collected every 15 min for the entire exposure length of 120 min via peripheral venous catheter except for the final sample, which was taken simultaneously from the contralateral arm via butterfly needle. Heart rate and SpO2 were continuously measured. Before and after each exposure, cognitive tests of short-term memory, working memory and attention were performed.

RESULTS: The 30 min of passive rest under NOR reduced the blood serum ($p<.001$) and plasma ($p<.001$) BDNF levels significantly. An extension of passive NOR have resulted in a continued decline in blood serum BDNF levels after an additional 45 min ($p=0.18$). Likewise, plasma BDNF levels exhibited further reductions after 30 min ($p=.040$) and 90 min ($p=.005$). Under NH BDNF levels remained stable. The two methods of blood collection (peripheral venous catheter vs. butterfly needle) did not differ. Furthermore, no effects on short-term memory or working memory functions were observed following NOR or NH. However, significant improvements in attention were observed after both conditions.

CONCLUSION: As expected, exposure to a passive NOR leads to a reduction in BDNF levels in serum and plasma. However, 90 minutes of NH exposure has no such negative effect. There is also no acute negative effect on short-term memory, working memory or attention. These results can therefore serve as an initial basis for counteracting the decline in BDNF caused by physical inactivity with the help of controlled hypoxia. This study also shows the need for a standardized protocol for future studies determining BDNF levels determinations in blood.

METHYLATION STATUS OF ACTN3 GENE: THE IMPACT ON INJURY RISK AND TIME-LOSS IN YOUNG BASKETBALL PLAYERS

JÒDAR-PORTAS, A., FORT-VANMEERHAEGHE, A.2, SACOT, A.1, FONT-LLADÓ, R.3, LÓPEZ-ROS, V.3, BARRETINA, J.4, ESTELLER, M.5, PRATS-PUIG, A.1, PLANS-SALAS, E.1
1.UNIVERSITY SCHOOL OF HEALTH AND SPORT , 2.RAMÓN LLULL UNIVERSITY; 3.UNIVERSITY OF GIRONA; 4.INSTITUTE FOR HEALTH SCIENCE RESEARCH GERMANS TRIAS I PUJOL; 5.JOSEP CARRERAS LEUKAEMIA RESEARCH

INTRODUCTION: The higher demands of the basketball game expose the athletes to some high injury risk situations. Gene variation is known to predispose athletes to injury, but also the epigenetic role has only recently been discovered. ACTN3 gene alteration has been related with deficiency in functional α-actinin-3, a key component of the skeletal muscle fast-twitch fibers. Although no single study has investigated the relationship between DNA methylation on ACTN3 gene with injury risk in basketball. The aims of the present study were (1) to compare the percentage of methylation of each ACTN3 CpG site between injured and non-injured players and (2) to investigate the relationship between the ACTN3 methylation and time-loss due to sport injuries.

METHODS: The sample included 57 young basketball players from 12 to 18 years old. The players were recruited from the youth teams of Bàsquet Girona club and performed three ninety-minute training sessions and a game per week. The experimental design of the DNA methylation study included a pre-test and a post-test assessment of salivary samples. The Illumina Methylation Epic Array v2.0 (Illumina) was used to analyse methylation status of 25 CpG sites within the ACTN3 gene. Injuries occurring throughout this period were recorded following the protocol outlined in the International Olympic Committee consensus and the OSICS classification system.

An independent sample t-test was used to compare the percentage of methylation of each ACTN3 CpG site between the injured and non-injured players. In the case of a not normal distribution, a Mann-Whitney test was used. The significance level was set at $p < 0.05$ and Cohens d was used to evaluate the effect size (values for d of ≤0.2, ≤0.5, and ≥0.8 are considered as small, medium, and large, respectively). Finally, Spearman's Rho correlation analysis was used to assess the relationship between methylation levels and time-loss. The protocol was approved by the ethics committee.

RESULTS: Significant differences in the percentage of DNA methylation levels between non-injured and injured basketball players were found at three CpG probes within the ACTN3 gene. Before the injury, the injured group showed hypomethylation on the cg20608119 probe ($p = 0.004$, $d = -0.912$, large differences) while after the injury, hypomethylation on the

cg10523820 (p = 0.004, d = -0.923, large differences) and hypermethylation on the cg18257026 (p = 0.042, d = 0.362, medium differences) probes were seen.

No significant relationship between pre-test methylation levels and time-loss were found. In contrast, at the post-test assessment a significant negative relationship between methylation levels and time-loss was found in cg10523820 (r = -0.416, p = 0.001).

CONCLUSION: Our preliminary data suggests that DNA methylation levels in ACTN3 differs between injured and non-injured young basketball players. Those epigenetic alterations seem to indicate that hypomethylation in ACTN3 could be related with more time-loss.

THE INFLUENCE OF SEX ON EXERCISE-INDUCED NUCLEAR FACTOR ERYTHROID 2-RELATED FACTOR 2 AND DOWNSTREAM TARGETS

THORLEY, J., ALHEBSHI, A., MARTIN, N.R.W., BISHOP, N.C., BAILEY, S.J., CLIFFORD, T.

LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Nuclear factor erythroid 2-related factor 2 (NRF2) is a transcription factor that regulates cellular resistance against oxidative distress and inflammation by coordinating the expression of key antioxidant and anti-inflammatory proteins. Moderate-to-high intensity exercise has been reported to increase NRF2 activity via oxidative cysteine modification of kelch-like ECH-associated protein 1, leading to redox-specific training adaptations. It is unknown, however, whether changes in exercise induced NRF2 and its downstream targets can vary depending on sex. Previous research has postulated that NRF2 activity is sensitive to oestrogen, which is greater in females vs. males. Thus, the aim of the study was to investigate whether NRF2 responses to an eccentric-heavy, plyometric-type exercise protocol. known to increase NRF2 activity, differed between males and females. It was hypothesised that exercise would increase NRF2 activity to a greater extent in females than in males.

METHODS: 22 males and females (mean [SD]: age: 25 [6] years, height: 171.3 [10.4] cm, weight: 69.6 [12.3] kg), who identified as recreationally active, performed 100 drop jumps from a 0.6 m box, followed by 50 squat jumps. NRF2/antioxidant response element (ARE) binding in peripheral blood mononuclear cells, and antioxidant and inflammatory markers influenced by NRF2 (glutathione peroxidase [GPX], interleukin-6 [IL-6], tumour necrosis factor-α [TNF-α], matrix metalloproteinase-9 [MMP-9], vascular cell adhesion molecule-1 [VCAM-1], total leukocytes, neutrophils, monocytes) were measured pre-, post-, and 1 h post-exercise. A 2 (sex) x 3 (time) linear mixed model was performed to detect time, group, and interaction effects. A statistical level of $p < 0.05$ was accepted.

RESULTS: NRF2/ARE binding did not significantly alter following exercise (p=0.59) and there were no sex differences at rest (MALES: 0.047±0.027; FEMALES: 0.045±0.018), post- (MALES: 0.047±0.028; FEMALES: 0.035±0.012), and 1 h post-exercise (MALES: 0.042±0.021; FEMALES: 0.037±0.020) (p=0.17). Regarding NRF2 gene targets, GPX activity did not change post-exercise (p=0.74) and did not differ between sexes (p=0.61). IL-6 and TNF-α did not increase post-exercise (p>0.05 for both) but were lower in females vs. males (p<0.01 for both). MMP-9 increased post-exercise (p=0.02), but no differences between sexes were found (p=0.27). VCAM-1 was unchanged after exercise (p=0.38) and did not differ between sexes (p=0.11). Total leukocytes, neutrophil, and monocytes all increased post-exercise (p<0.01 for all); neutrophils were lower (p<0.01), and monocytes higher (p=0.03) in females vs. males.

CONCLUSION: There were no sex differences in exercise-induced NRF2 activity, however, several inflammatory markers displayed sex-specific differences, independent to NRF2. This highlights the possibility of differential immune responses following exercise in males and females, which could impart variability in exercise recovery and training adaptations.

INDIVIDUAL MUSCLE HYPERTROPHY RESPONSES TO OVERLOAD PROGRESSION MODELS ARE NOT EXPLAINED BY CHRONIC CHANGES IN MYONUCLEI, SATELLITE CELLS, PROTEOLYSIS AND EXTRACELLULAR MATRIX REMODELING MARKERS

SCARPELLI, M., BERGAMASCO, J.1, CHAVES, T.1, GODWIN, J.2, MESQUITA, P.2, SILVA, D.1, DIAS, N.1, BITTENCOURT, D.1, UGRINOWITSCH, C.3,4, ROBERTS, M.2, LIBARDI, C.1

1 FEDERAL UNIVERSITY OF SAO CARLOS, BRAZIL, 2 AUBURN UNIVERSITY, USA, 3 UNIVERSITY OF SAO PAULO, BRAZIL, 4 UNIVERSITY OF TAMPA, USA

INTRODUCTION: The progression of overload in resistance training (RT) programs is traditionally performed by adjusting the load to a repetition maximum zone (LOAD). Yet, using a within-subject design, our group has shown that the progression of overload through increases in repetitions (REPS) promotes similar muscle hypertrophy compared to LOAD (1). Interestingly, despite group means results, some individuals showed greater gains in response to REPS. It is possible that this protocol may be differentially impacting mechanisms associated with muscle hypertrophy compared to LOAD. Our aim was to investigate if a higher responsiveness to REPS can be associated with changes in myonuclei and satellite cell content, proteolysis-related biomarkers and extracellular matrix (ECM) remodeling factors.

METHODS: Thirty-seven previously untrained young men (19) and women (18) had their legs randomized to one of two protocols: increasing load (LOAD) or repetitions (REPS). Participants underwent 10 weeks of RT. Vastus lateralis muscle cross-sectional area (CSA) ultrasound assessments and muscle biopsies were performed pre- and post-training period. Based upon the CSA responsiveness criteria we identified and analyzed a subcluster of 12 participants who were high-responders to REPS, i.e. between-legs difference in muscle hypertrophy was greater than twice the coefficient of variation calculated from the typical error (5.67%). We used immunohistochemical analyses to assess myonuclei and satellite cell

content; luminescence assays for measures of enzymatic activity; and western blotting for assessing protein contents of proteolysis and ECM remodeling biomarkers.

RESULTS: As per design, REPS promoted greater increases in CSA than LOAD (P = 0.004), with no differences in volume load (P = 0.93). Whilst controlling for pre values, the analysis of covariance showed no differences between REPS and LOAD for the relative change in: the content of myonuclei (P = 0.33) and satellite cells (P = 0.93); enzymatic activity of calpain (P = 0.47), proteasome (0.68) and MMP (P = 0.71); and protein content of calpain 1 (P = 0.92), calpain 2 (P = 0.71), 20S proteasome (P = 0.47), polyubiquitinated proteins (P = 0.87), P62 (P = 0.21), MMP9 (P = 0.58), MMP14 (P = 0.96) and TIMP2 (P = 0.07). There was a difference in the relative change of protein content of TIMP1 (P = 0.029), which was greater for LOAD compared to REPS.

CONCLUSION: Our results highlight that some individuals showed greater muscle hypertrophy gains after REPS, regardless of accumulating similar volume load in both protocols. This suggests individual manipulation of overload may improve responsiveness to training. However, different overload progression models do not differentially affect the chronic response of myonuclei, satellite cells, proteolysis-related biomarkers and ECM remodeling factors to RT.

OP-AP10 Talent Transfer

SUCCESSFUL TALENT TRANSFER OF GERMAN ELITE ATHLETES: REASONS AND MECHANISMS – AN INTERVIEW STUDY

SIENER, M., SCHMID, L., VOGT, T.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: In competitive sports, nations have an increased interest in identifying and developing talented athletes. However, only a handful of these gifted individuals make it to the top. This situation poses a challenge, especially for smaller countries with a potentially limited pool of promising athletes or budget. A talent transfer—meaning the transfer of already (semi)successful athletes to another sport—can be an opportunity to convert the support already made, ideally into a medal. However, clubs and associations often hesitate to release their athletes, having invested significant time and resources in them, which is not always in the interests of the athletes. Therefore, this study aims to identify motives and circumstances with a positive influence for a successful talent transfer.

METHODS: A total of seven German athletes (25±2 years; n♀=4) who had changed sports during their career were asked about their talent transfer using a guided interview. All participants are currently professional athletes, part of their national teams, and regularly compete internationally. The interviews focused on reasons for the switch, the transfer process, encountered challenges, differences between the original and new sports, and available support. The transcribed interviews were then analyzed using MAXQDA.

RESULTS: Interviewed athletes from the sports of gymnastics, athletics, volleyball, and swimming transitioned to pole vaulting, bobsledding, triathlon, rowing, or ski freestyle aerials at an average age of 19. Common reasons for switching included lack of motivation, enjoyment, or prospects for international success in their original sport. The athletes emphasized an importance of family support and noted similar physiological demands in the switched-to sport being helpful. Technical challenges were mitigated through gentle introduction with less pressure. The athletes supported a talent transfer but expressed concerns about the absence of organized programs in Central Europe and pointed in particular to the lack of support from clubs and associations for athletes switching sports.

CONCLUSION: Overall, there are a variety of possible reasons for a positive talent transfer. However, according to the athletes interviewed, similar physical abilities and a basic understanding of the fundamentals of the target sport appear to be crucial for a successful talent transition. Other studies show, such alignment can lead to rapid performance improvements, further endorsing successful talent transfers (Cury et al., 2022, doi: 10.1080/23750472.2022.2033638). In addition, there are already confirmed motivational and psychological effects that can ultimately be the cause of making a talent transfer (MacNamara, & Collins, 2015, doi: 10.1080/02640414.2014.908324). Although there are already promising talent development programs in Australia and Canada, the extent to which these can also be established in Germany and prevail against internal club interests remains to be investigated.

THE EFFECTS OF 10 WEEKS POLARIZED TRAINING ON THE CAPABILITY OF SHORT-DISTANCE SPRINT SKIING OF ELITE MALE TALENT-TRANSFERRING CROSS-COUNTRY SKIERS

CAI, X., MAO, L.2, CHEN, X.3

1 NANJING NORMAL UNIVERSITY; 2 SHANGHAI UNIVERSITY OF SPORT; 3 CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: Polarized training model could improve endurance performance of elite endurance athletes, and being used widely on modern cross-country (XC) skiing training [1,2]. In XC skiing competition, the short distance skiing competi-

tion demanding athletes need be both strong physiologically and tactically [3]. Aiming for XC skiing success at the Winter Olympic Games (WOG), China has developed a talent transfer program in which athletes from various summer sports by utilizing world class coaching and training methods [4]. However, the effects of long period polarized training on the capability of short-distance sprint skiing of elite male talent-transferring XC skiers are not clear.

METHODS: 10 elite male talent-transferring XC skiers [Age: (19.9±1.4) years old; Height: (178.5±4.3) cm; Weight: (70.0±5.6) kg; VO2peak: (78.8±6.1) ml·min-1·kg-1] of Chinese national XC skiing team took part in 10 weeks polarized training. 3 times XC short-distance sprint competition (the 1st, 6th and 10th week) and 3 times skiing-ergometer & watt-bike testing [the 1st (Week 3), 2nd (Week 4) and 3rd (Week 8) test] were organized during the 10 weeks training period. Training time and intensity were calculated on basis of recordings from heart rate (HR) monitors (Garmin 255, Garmin Ltd., USA) during 10 weeks training. Repeated-measures ANOVA test was used to compare athletes themselves between tests or competitions (the 1st test / Week 1 competitions, the 2nd test / Week 6 competitions, the 3rd test / Week 10 competitions). Significance was set at $P<0.05$.

RESULTS: Compared with the 1st test, the athletes' 5 groups average power output per kilogram of the 1.5 min and 1 min skiing-ergometer test were increased significantly (3.4%, 6.0% respectively; $P<0.05$) in the 3rd test. Compared with the competition results of the free technique and classic technique of the 1st week, the athletes' average time of qualification and quarter final were decreased significantly both in the Week 6 and Week 10 (Week 6, free 3.7%\3.9%, classic 1.0%\1.4%; Week 10, free 4.8%\3.8%. classic 1.8%/1.4%; $P<0.05$).

CONCLUSION: After 10 weeks polarized training, the athletes' capability of XC skiing-specific power output and competition performance of short-distance sprint skiing were increased significantly. In the future training, it is suggested that Chinese elite talent transferring XC skiers should add the running formed high intensity training (HIT) into training schedule, and insistent systematical XC skiing specific strength training and skiing-ergometer formed HIT sessions, to improve the capability of maximal oxygen uptake, continuously power output under high intensity, XC skiing specific strength and XC skiing specific power output.

NORDIC HAMSTRING EXERCISE: PEAK FORCE, ASYMMETRY AND THEIR DISTRIBUTION IN TOP-CLASS ADULT AND YOUNG FEMALE SOCCER PLAYERS

FRANCINI, L., RIBOLI, A., MAURELLO, F., SALVADOR, S., BOLDRINI, L., MAZZONI, S.

AC MILAN S.P.A.

INTRODUCTION: Several studies (1) suggested eccentric peak force (PF) and inter-limb asymmetry during Nordic hamstring exercise (NH) as factors possibly affecting hamstring injury risk (2). However, the information about PF and asymmetry during NH in top-class women soccer players are still lacking. Therefore, the current study aims to describe the PF and asymmetry during NH in adult and young female soccer players.

METHODS: One hundred and thirty-two female soccer players were involved (n=24 PRO, n=38 U19, n=33 U17, n=37 U15). After a standardized warm-up, NH were performed using a dedicated dynamometer (NordBord VALD, Australia). The injured players were excluded from data collection for at least 1 month after their return to team training; players with a severe hamstring injury during the previous 2 seasons were excluded. A total of 515 NH with ~7 (range: 5 to 19) NH for each player were collected. The PF was measured for each leg and for determining the weaker and the stronger leg. The inter-limbs asymmetry was calculated for both absolute (Newton, N) and relative (percentage, %) values using the following formula [absolute asymmetry = (strong leg - weak leg)] and [relative asymmetry = ((strong leg - weak leg) / (strong leg + weak leg)) * 100], as suggested in previous studies (3). The PF and asymmetry distributions are presented in terms of centiles (i.e. which describe the typical variation in the population). In a Gaussian distribution, some centiles correspond to the standard deviations of the sample (4). Therefore, the 50th (median), 84.13th (+1 SD), 97.72nd (+2 SD), 99.87th (+3 SD) percentiles were calculated (4). A t-test was used for comparisons between PF in weak vs strong leg; statistical significance was set at $P < 0.05$.

RESULTS: The 50th, 84.13th, 97.72nd and 99.87th percentiles for PF and asymmetries were calculated. The 50th percentile for PF and asymmetries were ~287 to ~312 N with 17.1 N (~2.8%) asymmetry in PRO, ~266 to ~281 N with 15.5 N (~2.9 %) asymmetry in U19, ~241 to ~364 N with 17.5 N (~3.5%) asymmetry in U17, ~204 to ~219 N with 13.7 N (~3.3 %) asymmetry in U15. The average PF was higher in strong than weak leg ($P<0.001$) in PRO (320±76 vs 295±70 N for strong vs weak leg, respectively), in U19 (283±41 vs 264±40 N), in U17 (260±36 vs 240±35 N) and in U15 (218±36 vs 203±35 N).

CONCLUSION: The present study describes the PF and asymmetry during NH in PRO, U19, U17 and U15 female soccer players. This information may help coaches and performance scientists for NH players' profiling and hamstring exercise prescription during training routine. The current results might be considered as a descriptive analysis of PF and asymmetries during NH exercises in elite women soccer population across different age-categories. The current results may open to further investigation about the association between PF and asymmetry during NH and hamstring injury risk in women's soccer.

PERFORMANCE CHANGES OVER TWO YEARS IN ELITE AEROBIC GYMNASTS TRANSITIONING FROM JUNIOR TO SENIOR CATEGORY

KYSELOVICOVÁ, O., KOTYROVÁ ŠTEFÁNIKOVÁ, G., ZEMKOVÁ, E.
COMENIUS UNIVERSITY IN BRATISLAVA

INTRODUCTION: Our preliminary case study revealed that an elite aerobic gymnast improved in the ability to maintain balance in dynamic conditions and repeated rebounds over two years of training. We were interested in whether and to what extent these changes in the key abilities of an aerobic competition routine would be reflected in a group of athletes. This study compares two-year changes in dynamic balance, explosive power and muscular endurance of lower limbs, isokinetic leg muscle strength, and anaerobic performance in elite aerobic gymnasts during their transitions from junior to senior category.

METHODS: A group of 8 aerobic gymnasts (age 16.2±2.5 y; height 164.1±2.7 cm; body mass 56.0±2.7 kg) performed a postural coordination test, Y-Balance test, countermovement jumps, 60 s test of repeated jumps, an isokinetic leg muscle strength test, and the Wingate test. Performance changes over two years of training were evaluated using a t-test with the significance level set at $p \leq 0.05$. The magnitude of the effect size was evaluated using Cohen's d.

RESULTS: Postural coordination improved by 31.3% (d=1.8) after two years of aerobic gymnastics training. Overall postural strategy index also increased from an average value of 7.2 to an excellent value of 8.1 (d=1.2). Distance reached in the Y-Balance test by the dominant leg increased in anterior (6.3%, d=0.5) and posteromedial (5.5%, d=0.7) directions, and by the non-dominant leg in anterior (by 6.6%, d=0.9) and posteromedial (3.5%, d=0.7) directions. The composite score of both the dominant and non-dominant leg also increased (6.0%, d=0.9, and 4.0%, d=0.7 respectively). Furthermore, the fatigue index in the 60 s test of repeated jumps decreased (from 37.0% to 28.9%, d=0.2). In addition, total work increased during dominant and non-dominant leg extension (12.2%, d=1.2, and 12.5%, d=1.3 respectively) as well as leg flexion at 300°/s (9.4%, d=0.6, and 4.2%, d=0.5 respectively). Similarly, mean power increased during dominant and non-dominant leg extension (15.5%, d=1.2, and 14.5%, d=1.2 respectively) as well as leg flexion at 300°/s (11.7%, d=0.5, and 12.0%, d=0.6 respectively). Peak torque/body weight ratio increased during dominant leg extension at 60°/s (15.3%, d=0.5) and dominant leg flexion at 300°/s (6.0%, d=0.7). However, two years of training failed to show any significant improvements in the explosive power of lower limbs and anaerobic performance.

CONCLUSION: These findings indicate that general aerobic gymnastic training without any specific inputs leads to performance improvements, namely in abilities closely related to competition routines such as dynamic balance, flexibility, and strength endurance of lower limbs.

ANTHROPOMETRIC AND PHYSICAL PERFORMANCE DETERMINANTS OF YOUNG TENNIS PLAYERS PROGRESSING THROUGH A TALENT IDENTIFICATION AND DEVELOPMENT PROGRAMME

CHAPELLE, L., DHONDT, J., DHONDT, E., CLARYS, P.
VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: Talent identification and development (TID) programs attempt to discover and develop young athletes with the potential to become successful (professional) athletes. This study examined the influence of both anthropometric and physical performance determinants on the likelihood to be selected to progress through a TID programme in youth tennis.

METHODS: Data were collected in 538 young tennis players (323 males and 215 females) from six age categories (U8-U13). A principal component analysis was used to generate 1 anthropometric determinant (based on body height, body weight and maturity offset) and 4 physical performance determinants: speed and agility (based on 5 m sprint, 20 m sprint and 505 change of direction test); jumping power (based on standing broad jump and standing broad jump in series); motor coordination (based on balancing backwards and jumping sideways) and tennis ball control (based on a throw and catch test and hold tennis ball up test). For all determinants, tertiles were generated for every age category and both sexes separately. Univariate binary logistic regressions were performed to examine the influence of each determinant on the chances to be selected to progress in the TID programme.

RESULTS: Significant odds ratios were found for all included anthropometric and physical performance determinants ($p<0.05$), ranging from 0.26 to 7.50 in the male young tennis players and from 0.18 to 6.87 in the female young tennis players. The included determinants influenced selection chances mostly in the early age categories (U8-U10) as opposed to the later age categories (U11-U13).

CONCLUSION: Future research should examine the influence of additional determinants (such as tennis (match-play) performance) on the selection chances to progress through a TID programme.

CHANGING BEHAVIOUR TOWARDS AEROBIC AND STRENGTH EXERCISE: RESULTS OF A RANDOMISED, PHASE I STUDY DETERMINING THE SAFETY, FEASIBILITY, AND CONSUMER-EVALUATION OF AN ONLINE EXERCISE PROGRAM IN PERSONS W

LEARMONTH, Y., KAUR, I., BAYNTON, S., WHITE-KIELLY, A., WALL, B., PAUL, L., FAIRCHILD, T.

MURDOCH UNIVERSITY; MURDOCH UNIVERSITY; MURDOCH UNIVERSITY; MURDOCH UNIVERSITY; GLASGOW CALEDONIAN UNIVERSITY; MURDOCH UNIVERSITY

INTRODUCTION: Many people with MS do not meet the recommended exercise guidelines to elicit health benefits. Programmes combining exercise prescription and behaviour change coaching lead to optimal outcomes. This study aimed to determine the feasibility, safety and participant evaluation of an exercise intervention, based on recent exercise guidelines and principles of behaviour change, delivered online to persons with MS.

METHODS: Seventy-two participants (age: 43.3 ± 13.3 years; mean ± SD) with mild to moderate MS were stratified according to previous exercise behaviour, and block-randomised into one of three groups: Control (CON; n=24), General Exerciser, (GE; n=24), and Advanced Exercisers, (AE; n=24). GE and AE received a four-month online-supervised exercise program including aerobic, resistance, balance, and flexibility training based on behaviour change theory. Participants completed questionnaires at baseline, four months, five months and eleven month. Process (e.g., recruitment), resources (e.g., monetary cost), management (e.g., staff time), and scientific (i.e., safety, outcomes, and participant evaluation) feasibility were assessed.

RESULTS: Of 198 potential participants, 143 met the eligibility criteria (72%) and 72 participants were randomised. Fifty-three participants completed the intervention (74% immediate retention), and 44 participants were retained at the six-month follow-up (61%). Personnel time was 369 hours, and the total per participant cost for the study is AUD $1036.20, including personnel costs. Adherence rate was 60% (GE), and 83% (AE) and self-reported online compliance was 73% (GE) and 38% (AE) of the prescribed exercise sessions. When considering safety (e.g., number of participants experiencing a change in MS symptoms) there were no differences in safety outcomes when comparing GE (n=9), AE (n=10) and control (n=10) participants.

CONCLUSION: We conclude that it is feasible, safe, and efficacious to deliver a remote exercise program with updated exercise guidelines and embedded with behaviour intervention to persons with mild-to-moderate MS. Future research should focus on determining the feasibility and acceptability of exercise prescription combined with behaviour changes to meet the recent guidelines at a wider scale across other MS populations, and to consider the feasibility of similar exercise programme delivery across neurological populations.

HEALTH-RELATED QUALITY OF LIFE ASSOCIATED WITH FATIGUE, PHYSICAL ACTIVITY AND PACING IN ADULTS WITH CHRONIC CONDITIONS

BARAKOU, I., SEVES, S., ABONIE, U., FINCH, T., HACKETT, K., HETTINGA, F.

NORTHUMBRIA UNIVERSITY

INTRODUCTION: Fatigue and inactivity are linked to decreased health-related quality of life (HRQoL) in adults with chronic conditions. A multidimensional approach to activity pacing targeting physical, psychological, and social factors holds promise for improving HRQoL through promoting physical activity engagement and alleviating fatigue. A transdiagnostic approach to fatigue in adults with chronic conditions is crucial, especially when underlying causes are unknown. Such approaches offer a comprehensive understanding of fatigues multidimensionality, valuable for researchers and clinicians. This study aimed to examine (1) associations between HRQoL and indices of fatigue and pacing in adults with chronic conditions, including perceived fatigue, engagement in pacing, perceived risk of overactivity, physical activity (self-reported & device-based), self-regulation of physical activity, and (2) if these associations are different for the subscales physical, social, emotional, and functional well-being.

METHODS: Survey and ActiGraph (7 days) data of 66 adults with chronic conditions, experiencing fatigue, were collected. Multivariable linear mixed model analyses were performed. First, HRQoL was the dependent variable, and one of the six indices of fatigue and pacing factors was the independent variable together with confounders: pacing groups, gender, age, body mass index (BMI), duration of condition, and years of fatigue management advice. Second, interaction effects with the HRQoL domains (physical, social, functional, and emotional well-being) were added to the models.

RESULTS: HRQoL was significantly associated with fatigue(B=-7.82; p=<.001), engagement in pacing(B=-.23; p=.006), self-regulation of physical activity(B=0.11; p=.013), and self-reported physical activity(B=1.32; p=.046), when corrected for confounders. Significant interaction effects were found in the models with fatigue, engagement in pacing, perceived risk of overactivity, and self-reported and device-based physical activity.

CONCLUSION: Reduced fatigue is associated with enhanced HRQoL, while corrected for confounders, stressing the significance of effective fatigue management. Higher levels of self-regulatory behaviour in physical activity, corrected for confounders, and increased physical activity are linked to enhanced HRQoL, emphasising the benefits of appropriate physical activity behaviours. Lower levels of fatigue, more engagement in pacing and higher levels of physical activity have a

greater impact on the physical subscale of HRQoL compared to the other subscales. Higher levels of perceived risk of overactivity and physical activity have a greater impact on the social subscale of HRQoL. The overall findings provide insights into the relationships between fatigue, pacing, self-regulation, physical activity, and their associations with HRQoL and well-being aspects underscoring the importance of a multidimensional approach to fatigue management.

EFFECTS OF A MULTICOMPONENT EXERCISE INTERVENTION ON CARDIOMETABOLIC RISK FACTORS IN CHILDREN AND YOUNG ADULTS WITH CP: A CROSS-OVER TRIAL

SAVIKANGAS, T., VALADÃO, P.F.1, HAAPALA, E.A.2, JUUTINEN FINNI, T.1
UNIVERSITY OF JYVÄSKYLÄ

INTRODUCTION: Adults with cerebral palsy (CP) have a higher risk of cardiometabolic diseases compared to the general population, but it is unknown whether this risk is elevated already in childhood and young adulthood. In addition, the evidence on the effects of exercise on cardiometabolic risk in young people with CP is limited. Therefore, we investigated the effects of a multicomponent exercise intervention on cardiometabolic risk factors in children and young adults with CP and compared this risk to typically developing (TD) controls.

METHODS: The EXECP study included 13 males and 5 females, aged 9–22, with CP and 17 age- and sex-matched TD controls. The participants in the CP group were measured at baseline, after a 3-month control period and after the 3-month EXECP intervention. TD participants were measured twice during the control period, without participating in the intervention. The intervention consisted of supervised, progressive, and individualized strength, walking, and flexibility training 2–3 times/week, along with treadmill walking at home for 10 min/day with a focus on stepping. Body weight, whole-body fat percentage, and skeletal muscle mass index (kg/m2) were measured using bioimpedance. Systolic and diastolic blood pressure and pulse wave velocity were measured in a supine position from the left arm with an oscillometric device. Plasma LDL and HDL cholesterol, triglyceride, and glucose levels were assessed from fasting blood samples. Between-group differences in the first measurement were analyzed with independent samples t-tests and Mann-Whitney U tests. Within-group changes in cardiometabolic risk factors were analyzed using age- and sex-adjusted linear mixed-effects models, in which the participant was included as a random effect.

RESULTS: Participants with CP had 1.0 kg/m2 lower skeletal muscle mass index ($p=0.040$) and tended to have 0.4 m/s higher pulse wave velocity ($p=0.062$) compared to TD controls. During the control period, body weight increased by 1.9 and 0.9 kg in the CP and TD groups, respectively ($p\leq0.05$). In addition, pulse wave velocity decreased ($\beta=-0.44$, $SE=0.16$), and whole-body fat percentage ($\beta=1.22$, $SE=0.72$), skeletal muscle mass index ($\beta=0.13$, $SE=0.07$), and blood glucose ($\beta=0.18$, $SE=0.10$) tended to increase in the CP group. During the intervention, no statistically significant changes were observed in any cardiometabolic risk factor in the CP group.

CONCLUSION: Children and young adults with CP did not differ from their TD peers for most cardiometabolic risk factors. Still, lower skeletal muscle mass index may predispose them to functional limitations and higher pulse wave velocity to elevated cardiovascular disease risk. The three-month exercise intervention focusing on strength training and gait quality was not successful in lowering cardiometabolic risk in children and young adults with CP. Longer duration and greater volume and intensity of aerobic exercise may be needed.

RELIABILITY OF THE BROCKPORT PHYSICAL FITNESS TEST IN COLOMBIAN BOYS, GIRLS AND ADOLESCENTS WITH INTELLECTUAL DISABILITIES AGED 10 TO 17 YEARS

CAMARGO ROJAS, D.A., ROJAS CANO, L., HERNANDEZ ALVAREZ, H., MEDINA ARIAS, C., MEDINA GARZÓN, P.M.
UNIVERSIDAD NACIONAL DE COLOMBIA

INTRODUCTION: The Brockport Physical Fitness Test Battery (BPFT) is an assessment tool designed for children and adolescents with intellectual disabilities (1), which has been used nationally (2) and internationally (3) to determine the level of physical fitness. The instrument lacks reliability values for the Spanish-speaking population, hindering the development of intervention programs with health benefits (4) and public policies aimed at promoting physical activity and exercise. This research aimed to determine the reliability of the Brockport Physical Fitness Test Battery in children and adolescents aged 10 to 17 years with intellectual disabilities.

METHODS: An assessment of the BPFT was conducted, including tests for body fat percentage, the sum of triceps and calf skinfolds, grip strength, push-ups, modified sit-ups, trunk lift, backsaver sit-and-reach, shoulder stretch, and PACER, on 56 children and adolescents with intellectual disabilities, aged 10 to 17 years, belonging to 2 educational institutions in the city of Bogotá, Colombia. The assessment was carried out by 4 expert evaluators at 3 different times; internal consistency analysis was performed using Cronbachs Alpha coefficient, test-retest analysis established the Intraclass Correlation Coefficient (ICC) and Spearman coefficient, as well as intra-evaluator reproducibility. Lastly, Cohens Kappa coefficient and ICC were calculated for inter-evaluator reproducibility analysis.

RESULTS: Acceptable levels of reliability were observed for the BPFT. Internal consistency obtained a Cronbachs Alpha >0.6 with the elimination of the PACER and modified sit-up items, ICC values >0.8, Spearman coefficient and ICC >0.9, and Cohens Kappa 1.0 corresponding to test-retest reliability, intra-evaluator reliability, and inter-evaluator reliability for each of the items composing the instrument.

CONCLUSION: The BPFT is a reliable and reproducible instrument for children and adolescents with intellectual disabilities in Colombia. It is recommended to review the selection of the modified sit-up item due to the risk of injury and its contribution to the construct of physical fitness for health. Also, it was observed from this research that certain elements of the test

do not contribute to the internal consistency of the instrument or to the construct of physical fitness for health in the population. Among them are the Modified Curl-up and the PACER, which have already been described by some authors as tests that have no validity or require familiarization by the participants.

EFFECTS OF PHYSICAL ACTIVITY HABITS IN CARDIOMETABOLIC HEALTH IN ADULTS WITH ACHONDROPLASIA

ALVES, I., CASTRO, M.A., TAVARES, S., ALVES, E., FERNANDES, O.
ÉVORA UNIVERSITY, PORTUGAL

INTRODUCTION: Achondroplasia (ACH) is a rare skeletal dysplasia characterised by short disproportionate stature, increased cardiovascular disease and tendency to obesity [1]. Reduced physical fitness, muscle strength and lung capacity have been reported in adults with achondroplasia (AwACH) [2]. The cardiorespiratory functional capacity is influenced by body size, physical activity level (PAL), and genetics [3]. We hypothesise that higher levels of regular physical activity are associated with better physical fitness, lower adiposity, and cardiometabolic optimization in AwACH.

METHODS: Participants performed a maximal treadmill exercise test to measure metabolic parameters: VO2max, peak VO2 (pVO2), peak ventilation (pV), maximum heart rate (maxHR), anaerobic threshold (AT), and functional Capacity (FC). Anthropometrics were collected and body composition parameters as fat mass (FM%), lean mass (LM%) and water (BW%) percentages, were estimated by bioimpedance. Physical fitness, with the 6 minutes walking test (6MWT) and strength test by handgrip strength (HGS) were performed. The International Physical Activity questionnaire (IPAQ) was self-administered to obtain a PA score (PAS) and PAL.

RESULTS: Seven AwACH, 4 women, mean age 37.3±11.9 years, body weight 53.7±15.2kg and height 129.0±13.9cm. Based on PAS (723±768 MET-min/week), two groups were identified: PAL1 (n=5) and PAL2 (n=2), inactive and minimally active, respectively. Multivariate analyses revealed PAL2 significantly outperformed PAL1 across functional exercise capacity and cardiovascular fitness indicators. Significant differences ($p<0.05$) existed between groups in favour of PAL2 on FC (3.924), pVO2 (2.847), VO2max (4.055), AT (2.564), 6MWT (3.03), PAS (3.176) and height (3.752). PAL2 participants showed lesser 15.52% FM% and 2.7bpm maxHR. Strong correlations ($p<0.001$) existed between HGS and pV (0.955), VO2max and PAS (0.967) and FM% (-0.842), indicating lower cardiometabolic risk, favouring PAL2. Other correlations ($p<0.01$) were found between pVO2 and HGS (0.939), bW (0.928) and LM with AT (0.873). VO2max predictors were identified: FM ($R2=0.709$) and 6MWT ($R2=0.699$), $p<0.01$.

CONCLUSION: These preliminary results show that increased PA is associated with cardiorespiratory function in AwACH, which can improve cardiometabolic health. Higher PAL showed association with lower FM% mass and maxHR. The 6MWT and HGS may represent surrogate markers of fitness and are promising clinical proxies for exercise tolerance in AwACH. Results provide insights in developing strategies to increase PA among AwACH for cardiometabolic optimization.

OP-PN28 Exercise for postmenopausal women

ACUTE METABOLIC RESPONSES TO RESISTANCE TRAINING SESSIONS DIFFERING IN SET CONFIGURATION IN POSTMENOPAUSAL WOMEN.

NINE, I., RIAL-VÁZQUEZ, J.1, FARIÑAS, J.1, RÚA-ALONSO, M.1, REVUELTA-LERA, B.1, RIVERA-MEJÍA, S.L.1, CLAVEL, I.1, MÁRQUEZ, G.2, IGLESIAS-SOLER, E.1
UNIVERSITY OF A CORUNA / Q6550005J

INTRODUCTION: Postmenopausal women are more susceptible to encountering diverse metabolic disorders, often with changes in body composition, energy metabolism, muscle mass and strength reduction (1). Manipulation of set configuration modulates acute responses to resistance exercise (2) modifying the intensity of effort, by the redistributing of the repetitions and rest periods (3). This study aimed to compare acute metabolic responses to training sessions differing in set configuration in a sample of postmenopausal women.

METHODS: 50 physically active postmenopausal women participated in this study funded by the Spanish Ministry of Science and Innovation (PID2021-124277OB). Three resistance training (4 exercises) and a control session (CON) were randomized. The exercises were performed using a 12RM load, differing in set configuration while maintaining the same volume (36 repetitions): 9 sets of 4 reps (4S), 6 sets of 6 reps (6S), and 4 sets of 9 reps (9S). Inter-set rest intervals were 45, 72 and 120 seconds, respectively, ensuring an equivalent work-to-rest ratio.

Oxygen uptake (VO2), carbon dioxide production (VCO2) and respiratory exchange ratio (RER) were recorded before (PRE: 15min) and after (POST: 60min) each session and averaged over 10min intervals. Blood lactate concentration (La) was sampled before and 1min after session. A 4x7 ANOVA analyzed set configuration effects on energy expenditure responses over time (PRE: 5-10min; and POST: 0-10, 10-20, 20-30, 30-40, 40-50, 50-60min), and a 3x2 ANOVA assessed lactate levels (PRE and POST).

RESULTS: The analysis showed a main effect of session, moment and session×moment interaction (p=0.005) for VO2, RER and La.

Greater VO2 values were observed in 9S and 6S compared with CON (p=0.006), with a tendency of 4S to be higher than CON (p=0.059). Higher VO2 was recorded in the first 10min POST compared to PRE and subsequent intervals (p=0.002). VO2 was only increased after 9S (POST 0-10) compared with PRE (p<0.001). Compared to CON, VO2 POST remained higher in 9S until 40-50min of recovery (p=0.039); in 6S until 30-40min (p=0.014) and in 4S only for the first 10min (p=0.002).

Baseline RER values were similar across all sessions, with PRE > POST (p<0.001). Overall, CON showed higher values (p=0.036) than experimental sessions, with 9S recording the lowest values (p=0.037). La POST was significantly higher than PRE in all sessions, with greater values in 9S compared to 6S and 4S (9S>6S>4S) (p<0.001). For VCO2 only a time effect (p<0.001) was detected (POST 0-10 > the rest of periods).

CONCLUSION: By maintaining the same volume and work-to-rest ratio, no differences in total energy expenditure were found, however only long set configuration (9S) promoted VO2 increase immediately after exercise. Set configuration may modulate the metabolic response after strength exercise, with shorter sets promoting lower La compared with longer sets.

CARDIAC AUTONOMIC MODULATION AND BAROREFLEX SENSITIVITY IN POSTMENOPAUSAL WOMEN: ACUTE RESPONSES TO RESISTANCE TRAINING SESSIONS DIFFERING IN SET CONFIGURATION.

VAZQUEZ, J.R., RÚA-ALONSO, M., NINE, I., FARIÑAS, J., REVUELTA-LERA, B., RIVERA-MEJÍA, S.L., IGLESIAS-SOLER, E.
UNIVERSITY OF A CORUNA

INTRODUCTION: Hormonal changes of menopause impact on womens health (1). Resistance training is recommended on reducing the risk of cardiovascular disease (2), but manipulation of set configuration has been found to influence the acute decrease in cardiac parasympathetic modulation (3). The aim of this study was to explore cardiac autonomic modulation and baroreflex sensitivity after resistance training sessions differing in set configuration.

METHODS: 50 physically active postmenopausal women (37 normotensive-13 hypertensive) participated in this study funded by the Spanish Ministry of Science and Innovation (PID2021-124277OB). After a medical exam and familiarization, women completed in a randomized order one control (CON) and 3 experimental sessions (4 exercises): 9 sets of 4 repetitions with 45s of inter-set rest (9S); 6 sets of 6 repetitions with 72s of rest (6S) and 4 sets of 9 repetitions with 120s of rest (4S). Before and after each session, cardiac autonomic modulation [root mean square of differences between adjacent pulse interval (RMSSD), heart rate (HR), high frequency power (HF) and sample entropy (SampEn)], baroreflex sensitivity (BRS) and its effectiveness (BEI) was evaluated at rest.

4x10ANOVA was used to analyze the effects of set configuration across time for cardiac autonomic modulation (Baseline and post-sessions: 5-10, 10-15, 15-20, 20-25, 25-30, 30-35, 35-40, 40-45, 45-50min). 4x5ANOVA was used to analyze baroreflex sensitivity (Baseline and post: 5-15, 15-25, 30-40, 40-50min).

RESULTS: No differences between normo- and hypertensive women were observed. CON values for all parameters were greater after sessions compared to experimental sessions (regardless HR, which was lower).

ANOVA detected a main effect of session, time, and session×time interaction (p<0.05) for RMSSD, HF, HR, BRS and BEI. The decrease of RMSSD and HF after 6S and 9S was greater compared to 4S (p<0.05). Compared to baseline, RMSSD was attenuated until 15min, 25min and 30min after 4S, 6S and 9S respectively (p=0.033). HF was decreased up to 20min, 25min and 30min after 4S, 6S after 9S respectively (p=0.016). Overall, FC was greater after 9S and 6S compared to 4S, being increased until 25min after 4S and 6S and up to 35min after 9S (p<0.05). Similar values of SampEn were observed between experimental sessions, being greater in CON. BRS was attenuated until 10min after 4S, and up to 25min after 6S and 9S and BEI was decreased until 15min only after 9S (p>0.05).

CONCLUSION: Experimental sessions produced a reduction of cardiac parasympathetic modulation and cardiac baroreflex activity, being longer sets which produced a greater drop in comparison with short sets. Results agree with previous findings in healthy young subjects (3). Short set configurations should be recommended for post-menopausal women.

EVALUATING CARDIAC GEOMETRY AND FUNCTION IN EARLY POST-MENOPAUSAL ATHLETES: AN ECHOCARDIOGRAPHIC STUDY

HENLEY-MARTIN, S., BRADE, C., COLLIS, J., NAYLOR, L., SPENCE, A.
CURTIN UNIVERSITY

INTRODUCTION: Menopause is a critical phase in female reproductive ageing and is characterised by a rapid decline in oestrogen. Due to its cardioprotective effects, cardiac health is particularly affected. Exercise exerts protective effects on cardiovascular health to mitigate the age-related decline, preserving function and maximal aerobic capacity. While studies in men offer insight, female-specific responses regarding the impact of exercise on cardiac function in postmenopausal (PM) women is limited. This study assessed cardiac geometry and function in early PM women who identified as athletes (AT) compared to recreationally active healthy controls (CO).

METHODS: Twenty women (age 56.9±3.9 y), classified as Stage +1c using the STRAW staging system (4.5±2.2 y post-final menstrual period) participated. Cyclists/triathletes (AT, n=10) and CO (n=10) were matched for age and hormone replacement therapy use (pooled n=8). Resting transthoracic echocardiography was used to assess diastolic function (medial e' cm/s; lateral e' cm/s; E/e' ratio; indexed left atrial volume LA ESVi mL.m-2), stroke volume (SV mL), ejection fraction (EF %). Left ventricular mass (LVMi g/kg) and end-diastolic volume (EDVi mL/kg) were both indexed to lean mass (kg) while speckle-tracking echocardiography assessed LV global longitudinal strain (GLS%). Resting heart rate (HR bpm), resting mean arterial pressure (MAP, mmHg), peak oxygen consumption (VO2peak mL.kg.min-1), DXA-derived body composition (lean mass kg; body fat %) and physical activity (PA mins/wk) were also assessed. Student's t-test was used to assess significance between groups (p<.05).

RESULTS: VO2peak (41.7±5.4 v 33.2±3.3 mL.kg.min-1 p<.001) and PA (1000.0±202.3 v 200.0±77.6 mins/wk p<.001) were significantly higher in AT compared to CO, while resting HR (47±5 v 55±6 BPM p<.005) and MAP (82±8 v 92±9 mmHg p<.05) were significantly lower in AT. Lean mass did not differ between groups (45.2±3.8 v 48.8±5.0 kg p=0.085) but body fat % was significantly lower in AT compared to CO (27.4±2.4 v 32.1±4.3% p<.05). No significant difference was found for cardiac geometry (LVMi 3.1±0.4 v 3.0±0.4 g/kg p=0.512; EDVi 2.2±0.3 v 1.9±0.3 mL/kg p=0.077), systolic (SV 65.4±8.9 v 63.3±11.1 mL p=0.639; EF 66.9±7.1 v 67.0±4.2% p=0.951) or diastolic function (medial e' 7.7±2.1 v 7.2±1.7cm/s p=0.600; lateral e' 11.0±2.5 v 10.5±2.3cm/s p=0.629; E/e' 9.0±2.6 v 9.5±1.9 p=0.620; LA ESVi 36.6±9.6 v 35.3±11.5mL/m2 p=0.790). No significant difference was observed for GLS (-23.0±1.3 v -22.0±1.8% p=0.177).

CONCLUSION: Despite significantly lower resting HR, lower MAP and improved VO2peak in PM athletes, we observed no cardiac geometrical or functional differences between PM athletes and recreationally active controls, when studied at rest. The greater aerobic capacity in PM athletes may therefore be due to improved cardiac functional reserve as well as peripherally-mediated mechanisms such as enhanced oxygen extraction efficiency and thus warrants further investigation.

SYNDECAN-1: A MARKER OF ENDOTHELIAL GLYCOCALYX DEGRADATION IN POST-MENOPAUSAL WOMEN

AYYALASOMAYAJULA, M., DELGADO, J., DAMANI, J., PROCTOR, D.N.
PENNSYLVANIA STATE UNIVERSITY

INTRODUCTION: The endothelial glycocalyx (eGC) forms a critical protective barrier made of glycoconjugates, which include carbohydrates linked to various molecules such as amino acids, proteins, and lipids [1, 2]. In aging and cardiovascular disease (CVD), the eGCs integrity is compromised, possibly preceding conventional markers of age-related vascular dysfunction, like impaired endothelium-dependent dilation and increased arterial stiffness [3]. Syndecan-1, a heparan sulfate proteoglycan expressed in endothelial cells, serves as a key biomarker of endothelial function and glycocalyx degradation [4]. Previous research has demonstrated that in endothelial cells (ECs), the glycocalyx plays a critical role in mediating nitric oxide (NO) production. Degradation of the endothelial glycocalyx layer (eGC) significantly diminishes ECs ability to produce NO in response to fluid shear stress. Estradiol is known to protect the endothelial glycocalyx (eGC) from shedding. Consequently, the reduction in estrogen levels around menopause may lead to symptoms that impact womens well-being and health, coinciding with eGC shedding [2, 5]. Therefore, we aimed to investigate the impact of menopause on glycocalyx degradation by comparing plasma concentration of Syndecan-1 in the early-postmenopausal and late-post menopausal women. We hypothesized that late-menopausal women would exhibit higher Syndecan-1 concentrations compared to early-menopausal women, indicating increased eGC degradation.

METHODS: Plasma samples were collected from early and late postmenopausal women and analyzed using enzyme-linked immunosorbent assay (ELISA) to measure Syndecan-1 concentrations. Independent sample T-tests were employed to assess differences between early and late postmenopausal groups. Alpha was set to 0.05.

RESULTS: Early post-menopausal women (n=12) were significantly younger with fewer years since menopause (Age: 56 ± 4 yrs; Years since menopause: 4 ± 2) compared to late postmenopausal women (n = 13) (Age: 63 ± 4 yrs; Years since menopause: 14 ± 5). All postmenopausal women were normotensive and healthy. Early postmenopausal women exhibited significantly lower plasma concentrations of Syndecan-1 compared to late postmenopausal women (Early: 29.65 ± 7.26 ng/ml; Late: 41.93 ± 15.03 ng/ml; p = 0.017).

CONCLUSION: Late-postmenopausal women demonstrate higher circulating Syndecan-1 concentrations, indicative of increased glycocalyx degradation compared to early-menopausal women. These findings underscore the potential implications of menopause for vascular health and highlight the need for further research and targeted interventions to mitigate glycocalyx degradation and potentially enhance endothelial function in menopausal women.

EFFECT OF DIFFERENT SET CONFIGURATION ON MECHANICAL PERFORMANCE OF POSTMENOPAUSAL WOMEN DURING BENCH PRESS EXERCISE.

LENS-VALES, A., FARIÑAS, J., OVIES-GUTIÉRREZ, F., RÚA-ALONSO, M., NINE, I., RIAL-VÁZQUEZ, J., REVUELTA-LERA, B., GIRÁLDEZ-GARCÍA, M.A., IGLESIAS-SOLER, E.

UNIVERSITY OF A CORUÑA

INTRODUCTION: In order to counteract the negative effects of hormonal changes, resistance training is strongly recommended for postmenopausal women (1). Furthermore, different organizations recommend different levels of resistance training according to age. The strength training prescription may be designed manipulating training parameters, and it has been shown that set configuration can modulate velocity and power losses, resulting in different levels of fatigue (2), but this has primarily been investigated in healthy and young individuals. The aim of this study was to compare the effects of different set configurations on mechanical performance of postmenopausal women during a bench press exercise.

METHODS: 50 physically active postmenopausal women took part in this study, funded by the Spanish Ministry of Science and Innovation (PID2021-124277OB). After a medical examination, each woman completed three experimental sessions in a randomised order. Each experimental session consisted of 36 repetitions of 4 exercises at 12RM (leg press, bench press, prone leg curl and lat pull-down), which differed in set configuration: 9 sets of 4 repetitions with 45 seconds rest between sets; 6 sets of 6 repetitions with 72 seconds rest between sets and 4 sets of 9 repetitions with 120 seconds rest between sets. Rest periods between exercises were 4 minutes. Throughout the exercise sessions, mechanical data were collected in bench press exercise (BP) (i.e. velocity (VL) and power (PL) loss). Explosive performance was also calculated before and after each session by performing 2 repetitions at maximum intended velocity at 70% of 12RM in bench press exercise.

RESULTS: Main effect of session ($p<0.001$) was found with significant lower reductions regarding VL in 4S (mean = 28.52%) compared with 6S (mean = 38.56%) and 9S (mean = 50.64%) and 6S compared with 9S. Similarly, to VL, a main effect of session ($p<0.001$) was detected for PL with lower in 4S (mean = 28.52 %) in comparison with both 6S (mean = 38.56 %) and 9S (mean = 50.64 %). For neuromuscular test, we found main effect for time ($p<0.001$), although we did not find main effect of session ($p=0.374$) nor moment x session interaction ($p=0.967$). Mean velocity in neuromuscular test was higher in the pretest (mean=0.638 m·s-1)) than in the posttest (mean=0.609 m·s-1).

CONCLUSION: Set configuration influences on mechanical performance of postmenopausal women in the bench press exercise. The 4S configuration allows to blunt velocity and power loss during BP exercise.

HEAD IMPACT ACCELERATIONS AND PUNCH ACCUMULATION OF FEMALE ELITE AMATEUR

CALLAN, J., WATCHORN, J.

SHEFFIELD HALLAM UNIVERSITY

INTRODUCTION: Repeated head impact accumulation may provide a marker of athlete welfare and training prescription in combat and contact sports. Instrumented mouthguards (IMGs) may provide insightful and detailed information to inform sparring, training and athlete monitoring. IMG data from elite boxing competition is currently limited. This case study presents the head impact data from an elite amateur female boxer.

METHODS: One elite female boxer (age = 26 years; mass = 70kg; stature = 173cm) took part in an international amateur boxing tournament (3 bouts = 3 x 2 mins:1 min recovery) whilst equipped with a Protecht IMG (OPRO+ smart mouthguard, UK) during each bout. The participant won all three bouts. Variables measured were linear head acceleration (g), angular head acceleration (rad·s), and number of head impacts. One-way ANOVAs ($p\leq0.05$) with omega squared ($\omega2$) effect size using JASP 0.18.1 were used to compare the following between bouts: mean g; mean rad·s; mean g split by 50th%, 75th% and 90th%; mean rad·s split by 50th%, 75th% and 90th%.

RESULTS: Bout 1: total impacts = 117; linear acceleration = 15.7±10.6g; angular acceleration = 3,802±3,272rad·s. Bout 2: total impacts = 58; linear acceleration = 14.6±9.1g; angular acceleration = 3,585±3,863rad·s; Bout 3: total impacts = 57; linear acceleration = 13.1±6.8g; angular acceleration = 3,251±2,244rad·s. There were no significant differences in mean g or rad·s between bouts. There were differences in mean g in the 75th% ($p = 0.04$, $\omega2 = 0.07$; bout 1 = 29.9±12.1g .v. bout 3

= 22.1±6.2g, post hoc p = 0.03) and in the 90th% (p = 0.2, ω2 = 0.23; bout 1 = 41.5±10.5g .v. bout 3 = 29.1±4.2g, post hoc p = 0.02) between bouts. There were no differences in mean rad·s between bouts split by %.

CONCLUSION: This participant experienced head accelerations lower than those reported from male combat sport and American football athletes [1]. The frequency of head impacts and the magnitude of linear accelerations reduced over the course of the three bouts, with no change in angular acceleration. These data provide novel information regarding head impacts in elite amateur female boxers. Future cohort studies for both sexes are required to better understand the effects of boxing competition.

THE HIGH ROTATION TEST COMPARED TO THE CKCUEST – THE ABILITY TO DIFFERENTIATE OVERHEAD ATHLETES WITH AND WITHOUT SHOULDER PAIN

SCHUHBECK, M., TAUBE, W., KEINER, M., BEINERT, K.

GERMAN UNIVERSITY FOR HEALTH AND SPORT

INTRODUCTION: Chronic shoulder pain is prevalent among overhead athletes (OA), from baseball pitchers to handball players, with pitchers reaching angular velocities over 7000°/sec for internal rotations (Fleisig et al 1999). Common physical performance tests, such as the closed kinetic chain upper extremity stability test (CKCUEST) cannot differentiate athletes with and without pain (Torabi 2024), probably because they do not test the rotational aspects of overhead motion. In addition, CKCUEST provides only one sinlge outcome measure, the "number of touches". This study introduces the High Rotation Test (HRT), performed in 90° abduction, addressing speed and rotation. The aim of the study was to compare the performance of patients with shoulder pain (Experimental Group, EG) and healthy controls (Control Group, CG) on HRT and the CKCUEST. Further, we also assessed joint position sense (JPS) and pain.

METHODS: In the study, 54 participants took part (EG, n=35, 38.3 ± 13.8 yrs.; 19 males; CG, n=19, 27.7 ± 7.2 yrs.; 9 males). Kinematic variables such as velocity (v), acceleration (a) and range of motion (ROM) were recorded for both HRT and CKCUEST, utilizing inertial motion units (IMU) (Captiv Motion System, TEA, France). IMU's were also used to assess joint position sense (JPS). Differences between groups were analysed with student´s t-test. Effect sizes were reported with Cohen´s d and correlations between the kinematic variables and pain were calculated with Pearson correlation coefficient.

RESULTS: Average pain intensity was 6.1 on a NRS for the EG and 0 for the CG. Significant differences in HRT performance were found between the EG and CG for repetitions [t(52) = 2.63, p = 0.011, d = 0.75] and velocity [t(52) = 2.68, p = 0.006, d = 0.82]. Further, the number of repetitions was significantly correlated to acceleration (r = .41, p = 0.002) and velocity (r = .43, p = 0.001). Regarding the CKCUEST, significant differences between EG and CG were found for repetitions [t(51) = 2.53, p = 0.015, d = 0.72] but not for velocity. Further, the number of repetitions was significantly correlated to acceleration (r = .64, p < 0.001) and velocity (r = .43, p < 0.001). Significant differences were also found for shoulder JPS [t(52) = -4.75, p < 0.001, d = 1.35]. Pain correlated with JPS (r = .39, p = 0.003) but not with velocity or acceleration.

CONCLUSION: Both tests show differences in repetitions between EG and CG. This is of clinical importance because repetitions are easily assessed in daily routine. Differences in peak velocity were identified with the HRT, but not in the CKCUEST. This might be an important parameter for determining the return to sports, as most OA rely on very fast rotational movements. Complementary to the functional tests, the limitation of shoulder patients in the JPS test may indicate the impaired sensory component of pain. Thus, it is recommended to use the HRT in combination with the JPS test in order to test for motor and sensory impairments in OA with shoulder problems.

CHANGES IN PUPILLARY LIGHT REFLEX FOLLOWING COMPETITIVE RUGBY UNION

BARNES, A., KIRK, C., HILL, R., BOWDEN, B., MERCER, J.

SHEFFIELD HALLAM UNIVERSITY

INTRODUCTION: Automated pupil light reflex (PLR) is a valid indicator of dysfunctional autonomic brainfunction following traumatic brain injury and may be a useful tool to triage patients [1]. Rugby union is characterised by repeated head accelerations, with high head acceleration events occurring more frequently in elite men's forwards than backs [2]. PLR may offer a more sensitive and objective means of detecting signs of brain dysfunction resulting from head accelerations without diagnosed concussion and may reduce the need for clinical judgments to inform player management. This study aimed to examine the impact of a competitive match on PLR variables.

METHODS: Twenty-nine adult male rugby players (16 Forwards, 13 Backs) playing level 4 rugby in the English league structure took part in the study. PLR of both eyes were measured pre and post a competitive match using a Neuroptic NPi-200. Pupillometry values including the Neurological Pupil Index (NPi), mean constriction velocity (CV), max constriction velocity (MCV), and dilation velocity (DV) were obtained. Differences between left and right eye were analysed pre- and post-match using a paired t-test. The averages of both eyes together were compared pre- and post-match, and between forwards and backs using a two-way mixed ANOVA.

RESULTS: The difference in DV between the left and right eye increased post-match (0.3± 0.1824 mm· s-1)compared to pre-match (0.14± 0.1324 mm·s-1, p=0.05). There was a significant main effect of match on both NPi (pre= 3.8 ±0.4 AU vs

post=3.5 ±0.4 AU, p=0.005) and DV (pre=1.25 ±0.24 mm·s-1 vs post=1.12± 0.18 mm·s-1, p=0.02). No main effect of position was seen for any variables, nor were there any observed interaction effects.

CONCLUSION: PLR was altered following participation in competitive rugby union. The lower NPi and DV values post-match suggest a change in autonomic brain function, in keeping with studies where concussions were clinically diagnosed [1]. Anisocoria also increased pre-post, reflecting previous data from mixed martial arts sparring without incidence of diagnosed concussion [3]. PLR offers a rapid and objective measure of autonomic brain function and could be a promising tool for player assessment, but further research is needed to establish the relationship of PLR to the number and severity of head impacts and the decay of these changes.

THE EFFECT OF COVID-19 ON AUTONOMIC NERVOUS SYSTEM FUNCTION IN AMERICAN FOOTBALL ATHLETES

RIFAT, S., MILLER, B., CHUNG, E., JOHNSON, P., SARNA, K.

CLEVELAND CLINIC

INTRODUCTION: SARS CoV-2, the respiratory virus causing COVID-19, is known to affect many organs and systems. Although most healthy, immune competent athletes fully recover, some continue to experience long term symptoms. Little is known about the causative mechanism of this phenomenon, however emerging evidence suggests that cardiovascular autonomic dysfunction may play a role. Autonomic dysfunction can manifest in many ways including disturbances in blood pressure, resting heart rate (RHR) and Heart Rate Variability (HRV). These parameters can be easily measured with popular wearable devices. To our knowledge this is the first study to prospectively investigate the effect of COVID-19 on cardiac autonomic function in American football players by using a commercially available wearable device.

METHODS: Forty American football players from the same team were enrolled in this prospective matched cohort study. Twenty who recovered from COVID-19 who were cleared to play after normal physical examination and normal cardiac testing (hs-troponin, echocardiography and cardiac MRI), and a matched cohort of 20 who were antigen negative at baseline and never tested positive for COVID-19 throughout the study period. All participants underwent 6-times per week COVID-19 testing throughout the study period. The control group was matched based on position including the following three groups; Linemen (L), Large Skill (LS) and Small Skill (SS). All participants wore a multi-sensor wrist device (WHOOP Inc., Boston, MA) that measured RHR, HRV, respiratory rate (RR) and hours sleep (HS) per night throughout a 6-week period during their competitive season. Statistical analyses were performed to evaluate the association between each individual categorical characteristic variable and COVID-19 history. Difference scores from last and baseline values for the entire study duration were calculated. General linear model analysis was done considering COVID-19 infection status and player position.

RESULTS: Twenty-nine players completed the study. Eleven were removed, 8 from the COVID-19 cohort and 3 controls because they did not wear the wrist band long enough to acquire a baseline. There was no statistically significant difference between the groups apart from the LS subgroup with a higher body mass index for the COVID-19 group (p=0.0460). Throughout the study period there was a statistically significant difference (p=0.0434) between RHR mean for the SS group with a higher mean of the mean in the COVID-19 cohort compared to the control group. There was no statistically significant difference between player position groups for any other variables.

CONCLUSION: COVID-19 does not appear to have significant long-term effects on HRV, RR and HS in American football players who fully recovered from COVID-19. Although the study group size was small, elevated RHR in the Small Skill group may indicate prolonged autonomic dysfunction after COVID-19 in these lean, highly conditioned athletes.

EFFECT OF HIGH-INTENSITY INTERVAL TRAINING ON CARDIOPROTECTION AGAINST RENAL ISCHEMIA-REPERFUSION INJURY IN RATS

TANG, C.Y., LAI, C., FU, S., TSAO, P., TSENG, K.

UNIVERSITY OF TAIPEI

INTRODUCTION: In recent years, High-Intensity Interval Training (HIIT) has gained popularity among athletes due to its ability to save exercise time, promote more efficient fat loss, and assist in improving disease prognosis. The results of this study will clarify whether HIIT can reduce myocardial damage caused by renal ischemia-reperfusion, with the aim of serving as a reference for exercise prescriptions in health promotion in the future.

METHODS: 30 male Sprague Dawley rats were divided into three groups: Sham (SHAM), Non-High-Intensity Interval Training (Non-HIIT), and High-Intensity Interval Training (HIIT). The SHAM group had no further intervention after abdominal opening, while the other two underwent 60 minutes of renal artery occlusion and 24 hours of reperfusion before being sacrificed. Blood samples were taken to assess Troponin-I and CPK levels, and ELISA measured serum TNF-α for apoptosis and inflammation. Heart tissues were also collected for HE and TUNEL staining to evaluate cardiac damage and myocardial apoptosis.

RESULTS: Blood test results revealed significant differences among the groups. Troponin I levels were markedly different between SHAM, CAO, and HIIT groups: 0.68 ± 0.47 vs. 298.08 ± 173.09 vs. 41.56 ± 10.44 ($p < 0.01$). Similarly, CPK levels showed substantial variations: 577.50 ± 19.40 vs. 8531.33 ± 591.00 vs. 3918.17 ± 1761.22 ($p < 0.001$). In the Elisa assay, TNF-α concentrations differed significantly among the groups: SHAM vs. CAO vs. HIIT: 39.12 ± 5.59 vs. 104.408 ± 6.62 vs. 62.31 ± 6.57 ($p < 0.001$). Additionally, HE staining indicated notable differences in myocardial damage quantification: SHAM vs. CAO vs. HIIT: 0.20 ± 0.08 vs. 3.65 ± 0.44 vs. 1.28 ± 0.32 ($p < 0.001$). Finally, TUNEL analysis showed significant variations in myocardial cell apoptosis rates: SHAM vs. CAO vs. HIIT: 2.3 ± 0.7 vs. 34.3 ± 5.5 vs. 19.7 ± 1.2 ($p < 0.01$).

CONCLUSION: Studies have shown that HIIT can significantly reduce plasma mRNA expression related to inflammation. It also helps lower Agt mRNA expression associated with the Renin-Angiotensin-Aldosterone System (RAAS), thus aiding in blood pressure reduction, and decreases Fan1 mRNA expression related to apoptosis, thereby preventing cell damage (1,2). Additionally, HIIT intervention has been found to reduce kidney weight and the ratio of kidney weight to body weight, indicating that this exercise modality can improve renal interstitial fibrosis, reduce kidney damage, and consequently mitigate myocardial damage (3). Our results demonstrate that four weeks of consecutive HIIT intervention before renal artery occlusion significantly reduces cardiac damage. From the perspective of primary and secondary disease prevention and treatment strategies, improving physical function through exercise represents one of the simplest and most cost-effective ways to enhance human health.

IDENTIFYING RISK PROFILES: INSIGHTS INTO INJURY SUSCEPTIBILITY AMONG YOUTH FLOORBALL PLAYERS

LEVIN, S., TERVO, T., IVARSSON, A., HÄGGLUND, M., STENLING, A.

UMEÅ UNIVERSITY

Introduction

Sport injuries are common in most sports, at elite level as well as among youth athletes. To reduce the occurrence of sport injuries, understanding the risk factors associated with injuries is essential. During the last decade, there have been calls in the literature for more holistic approaches to understand how combinations of factors affect injury risk. The aim of the present study was to employ a person-centered approach to identify combinations of psychological and physical factors that influence the risk of injury among youth floorball players.

Methods

In the beginning of the floorball season 222 youth athletes (age:15-19, female: n=97) underwent physical field tests and completed a baseline survey, which included demographic information and assessments of psychological well-being (i.e., depression and anxiety symptoms). At the end of the season, participants were asked to report any traumatic or overuse injuries experienced during the season. Latent profile analysis (LPA) was used to identify potential risk profiles among the athletes. We then conducted a covariate analysis with sex, age, height, weight, previous injury history and injury status at baseline as predictors of profile belonging. Finally, we compared injury risk between the identified profiles.

Results

The LPA resulted in a three-profile solution where profile 1 (n=101) reported above average psychological well-being and higher results on physical field test than the other profiles, whereas profile 2 (n=49) had lower psychological well-being than the other profiles, and profile 3 (n=72) performed the worst on physical field tests. Covariate analysis showed that athletes who were injured at baseline were more likely to belong to profile 2 when compared to profile 1, no other significant differences were observed. A total of 113 athletes (50.9%) reported an injury at the end of the season. The analysis of distal outcomes (traumatic or overuse injury) showed that profile 1 had a higher risk of any injury compared to profile 2 (risk difference RD=16.5%, 95% CI [-0.3-33.4]) and profile 3 (RD=15.0%, 95% CI [0.0-29.9]). Additionally, profile 1 exhibited a higher risk of acute injury compared to profile 3 (RD=16.6%, 95% CI [3.8-29.4]).

Discussion

Surprisingly, our findings revealed that the athletes with high physical ability and low levels of depression and anxiety had the highest risk of injury. One potential explanation could be that athletes in this profile engage in more practices and competitive games (compared to athletes in the other two profiles), which exposes them to more risk situations, higher physical load, and insufficient recovery. These findings have practical implications for seasonal planning and highlight the coaches role as key figures in assisting youth athletes to balance the demands of training intensity with adequate recovery.

NORWEGIAN ELITE HANDBALL AND FOOTBALL REFEREES' SELF-REPORTED INTENTION TO QUIT OFFICIATING: THE ROLE OF THE DUALISTIC MODEL OF PASSION.

JOHANSEN, B.T., ERIKSTAD, M.K., HAUGEN, T.
UNIVERSITY OF AGDER

Introduction

Researchers have raised concerns about sport referee attrition and its potential negative impact on the games quality [1]. Previous studies have highlighted that passionmay prevent dropout from sport activities [2,3], still empirical evidence from the context of sport refereeing is requiring. Hence, the aim of the present study was to investigate the predictive value of passion on intentions to quit among Norwegian elite sport referees.

Methods

The participants were 224 Norwegian elite referees of handball (n = 111, m age = 35.3 years, 13.5% females) and football (113, m age = 30.8 years, 8% females) who had been referees for an average of 14.4 years (sd = 7.77 years; min: 4, max: 37) and a referee at the present level for 6.8 years (sd = 6.20 years, min: 1, max: 32). In a section of the web-based survey was a question constructed based on the work of Van Yperen [4] assessing participants' intentions to quit as an elite referee (e.g., ˜Do you sometimes think about quitting as elite referee?'). The referees could choose between three alternative answers: 1. I never think about quitting, 2. I sometimes think about quitting, and 3. I often think about quitting. The 12-item Passion Scale [2,3] was used to assess the referees' type of passion that characterized their officiating.

Results

The number of complete cases for the present study was N = 184. Overall, 50.5 % (n = 93) of the referees had an intention to quit refereeing. A logistic regression was performed to assess the predictive value of harmonious passion and obsessive passion on the likelihood of intention to quit officiating. The logistic regression model was statistically significant, $\chi2(1,181) = 33.319$, $p < .001$. The model explained 22% (Nagelkerke R2) of the variance in intention to quit. The odds ratio for harmonious passion was 0.397, meaning that one unit increase on the harmonious passion scale (1-7) was associated with a decrease of 60 % in the odds of having an intention to quit officiating. Additionally, no statistically significant effect was found for obsessive passion on intention to quit officiating.

Conclusion

The present findings revealed that harmonious passion significantly decreased the likelihood of intending to quit officiating, emphasizing the importance of nurturing a positive and balanced passion in sports refereeing. The study offers insights that could help address concerns raised by researchers regarding elite sport referee attrition and its potential impact on game quality.

DEVELOPING RESILIENCE THROUGH COMMUNITY FOOTBALL; A FEASIBILITY STUDY.

MOLLOY, L., BEATTIE, S., CALLOW, N., HARDY, J., TUDOR-EDWARDS, R., ONG, C.W.
BANGOR UNIVERSITY

Introduction

Resilience has historically been viewed as an outcome or trait, with individuals who achieve better-than-expected outcomes despite dealing with adversity being considered resilient. More contemporary research suggests resilience may be a process, with both proactive and reactive elements. However, there has been little investigation as to how this more contemporary concept of a resilient as a process can be incorporated into specific interventions to develop resilience. In an established community football programme, we set out to explore ways that resilience may be developed as part of engagement in the programme, and the feasibility of conducting a specific resilience intervention.

Methods

The Resilience Process Scale – RPS (a 13-item scale assessing 4 stages of resilience: anticipate, minimise, manage and mend), CD-RISC 10 (10 item version of the Connor Davidson Resilience Scale), wellbeing (SWEMWBS) and physical activity levels using questions from the IPAQ were administered to 16 individuals partaking in a school-holiday based community sport programme at pre and post intervals following 4 coach-led and co-developed resilience sessions. Post-intervention qualitative analysis was conducted with participants via focus groups and coaches via 1-1 interviews to understand what aspects of the intervention were successful and where it can be improved.

Results

Quantitative analysis revealed improvements in the Manage aspect of the RPS, SWEMWBS Score and levels of physical activity approaching significance. Further investigations through thematic analysis of the focus groups and interviews revealed several key themes: coach relationship, social interaction and football as the 'hook' were revealed to be positive influences on session enjoyment and engagement.

Discussion

The findings suggest that, while improvements in resilience were statistically non-significant, participants felt they had learned some useful skills and had engaged well with the programme. This was echoed by coaches who enjoyed the opportunity to intertwine resilience theory with their coaching and had freedom to structure the sessions as they wished. This has several implications for practitioners and coaches looking to develop resilience interventions. Firstly, using a 'hook' or basing the intervention around an activity that participants would actively engage in will improve interest. Second, ensuring coaches are familiar and have a good relationship with participants will further increase engagement. Finally, giving coaches more freedom on how to implement the intervention content into the sessions will improve eagerness and motivation to engage in the process.

EXPLORING THE EXPERIENCES OF A CHINESE ATHLETE IN FACILITATING CAREER TRANSITION THROUGHOUT A PSYCHOLOGICAL SKILLS TRAINING PROGRAM: A NARRATIVE ANALYSIS

ZHANG, X., LUO, P.2, WANG, H.N.3, ZHANG, K.Y.4, LI, Y.5, AN, Q.5

1 UNIVERSITY OF CALGARY, 2 BEIJING SPORT UNIVERSITY, 3 WEST CHINA HOSPITAL OF SICHUAN UNIVERSITY, 4, SOUTHEAST UNIVERSITY, 5 CAPITAL UNIVERSITY OF PHYSICAL EDUCATION AND SPORTS

Psychological skills training programs have been consistently reported as an important part of preparation for optimal performance in high-performance settings (Weinberg & Gould, 2015), as well as for career transition and life skills development (Zhang et al., 2017; Zhu et al., 2023). Additionally, it has been noted that the specific sport context should be taken into consideration when delivering such a program (Si et al., 2015; Zhu et al., 2023). The Chinese sport system is characterized as a semi-closed environment in which Chinese athletes are able to focus on training but often have limited access to formal education and other people for connecting and networking , which subsequently leads to challenges when preparing for retirement at the end of their sport careers (Zhang et al., 2019).

The purpose of this paper was to explore the experiences of a Chinese volleyball player in facilitating career transition throughout a three-year psychological skills training program. An instrumental case study methodology with a narrative analysis approach was employed to illustrate the evolving application of psychological skills and the athlete's experiences.

The athlete spoke of the benefits derived from the psychological skills training program, and three patterns emerged: stories of how a player learned to plan for training and competitions; how she became reflective to prepare for career transition; and how she began to utilize the skills in life after sport.

This study provides insight into a psychological skills training program delivered within the Chinese sport system that facilitated the career transition of a Chinese volleyball player to be used in both sport and life out of sport.

PSYCHOLOGICAL FACTORS IN BASKETBALL TALENT IDENTIFICATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

HAN, M., LORENZO-CALVO, J.

UNIVERSIDAD POLITÉCNICA DE MADRID

Introduction

Identifying athletic talent involves assessing physical, motor, and psychological factors. Cognitive perceptual skills are crucial in basketball because they allow for quick decision-making and efficient movement [1]. Expert players use visual search strategies to predict outcomes, while novices struggle with effective gaze patterns. Although many studies have explored visual interventions with adult athletes, few studies have investigated the impact of visual perception, particularly in the selection of young athletes. This study conducted a systematic review and meta-analysis to identify psychological factors in basketball talent (1) to find out whether visual perception affects talent identification in youth players and (2) whether visual search behaviour training applies to youth players of all ages.

Methods

The search was carried out using the most relevant databases, such as Web of Science, PubMed, SPORTDiscus, and Scopus, according to the PRISMA (2020) guideline. Keywords such as 'basketball', 'talent identification,selection', 'psychological', 'perceptual cognitive', 'decision making', basketball, and 'visual' were used for the search in English, following the PICOS question model. Meta-analyses were performed using Cochrane Collaborations Collaboration Review Manager

5.4.1, an open-source programme. A total of 33 articles were evaluated for overall methodological quality using critical review forms.

Results

The findings highlight the complexity of the interactions between psychological factors, training interventions, and motor skills for identification in basketball talent. Visual perception affects their response time, shooting accuracy, and movement time during the game. Players visual behaviour and their reactions to opponents are influenced by factors such as peripheral vision. Expert players performed better in terms of visual behaviour. The role of reaction time, gender, age, and peripheral perception in predicting the role of vision and visual attention in improving performance is also stressed, as is the importance of focusing on the direction of the pass to mitigate the effects of high frequency.

Conclusion

The results demonstrated the importance of these psychological and perceptual factors in maximising the performance and success of the court. It also revealed the complex relationship between basketball players visual behaviour and performance, which indicated the viability of visual and motor performance assessment for coaches and scouts looking for talent.

OP-SH03 History

MEDIA TRANSITION AND SPORTS CELEBRITIES: THE INFLUENCES OF CHINESE SPORTS BROADCASTERS AND THE HISTORY OF CHINESE POPULAR CULTURE

LI, X., HUANG, L., BI, X.
BEIJING SPORT UNIVERSITY

Introduction: As one of the perspectives in cultural studies, celebrity studies has gradually become a hot topic in the intersection of sports and other disciplines [1]. However, sports media practitioners, who similarly possess celebrity attributes, have consistently been overlooked [2], perhaps attributable to the marginalized position of media studies within the tradition of sports research [3]. Indeed, in the progressive development of modern sport, the relationship between sport, media and social culture has become indivisible [4]. Taking the perspective of intergenerational changes in sports broadcasting brought about by media transitions, this study analyzes the characteristics of popular culture in the Chinese sports broadcasting industry during the modern development of sports. It identifies the interactive relationship between media transitions in China, sports broadcasting activities, and sports popular culture.

Methods : Through literature review and case analysis, this study examines the historical context and representative broadcast celebrities in the development of sports broadcasting in China. It explores the characteristics of sports broadcasting in different eras and uncovers the underlying popular cultural influences.

Results: In the more than 60 years since the development of sports commentary in China, media technology has made three significant changes to the way sports texts are presented, and sports broadcasters have thus demonstrated the temporal characteristics of "idols", "experts" and "micro-celebrities". They have thus participated in the production of sports popular culture characterized by "nationalized", "grouped", and "stratified".

Conclusion: The late popularization of television technology has led to a scarcity of professional sports broadcast resources in China. State-dominated sports events have made sports broadcasters play the role of transmitting national emotions, becoming "idol-style" leaders of popular culture, and shaping a "nationalized" popular culture through the expression of national identity emotions.

The rise of internet technology in the early 21st century has brought a surge of modern sports broadcast resources into China. Sports broadcasters have evolved into star figures as "experts" in a particular sport. Chinese sports audiences have been further categorized on this basis, with the emergence of a significant "grouped" of online community culture.

With the proliferation of social media, the decentralization of discourse in the online space has led to an influx of non-professionals into the sports broadcasting industry. These individuals, adopting non-traditional forms of discourse, have become "micro-celebrities" further fragmenting the sports audience "grouped" into "stratified" and resulting in a more polarized and divisive popular culture content.

THE HISTORY OF CHILDREN'S PLAY FROM AN EVOLUTIONARY PERSPECTIVE: A NARRATIVE REVIEW

LANGFORD, A., SHEEHAN, D., HANLON, M., FRANCIS, P.
SOUTH EAST TECHNOLOGICAL UNIVERSITY CARLOW

Introduction

Children's most common form of physical activity (PA) is play[1]. Play is something that children partake in voluntarily and is imaginary[2]. Evolutionary biologists argue that play is risky and metabolically expensive, and the energy could be better used for survival activities like scavenging and hunting[3]. However, play is seen throughout history and therefore must be essential in childhood. Play contributes to social and emotional skill development, and physical skills like strength and speed. The aim of the review is to understand children's play from an evolutionary lens and subsequently, design a PA intervention more in tune with human evolution.

Methodology

A search was conducted across four databases, including PubMed, ERIC, EBSCOhost, and Scopus. The search terms were "play" OR "physical activity" AND "prehistory" OR "modern history" OR "ancient history" OR "ancient Greece" OR "ancient Rome" OR "medieval history" OR "evolution" AND "children" OR "child". The inclusion criteria were that the article is in English and must discuss children's play. This search yielded 2122 results, and after applying the inclusion criteria, deduplication, screening of titles and bibliographies, 156 articles were included in the review.

Results

Prior to written history (3 million BCE-3000BCE), evidence for play comes from toys and artefacts made from clay and wood with children's fingerprints. By observing modern day hunter-gatherer tribes, rough and tumble games like chasing, gathering natural resources, and playing with spears equip children with life skills as adults. In Ancient Greece (6000BCE-650CE), philosophers like Plato promoted play as a learning tool. Paintings and sculptures on clay artefacts show games like tug-of-war and hopscotch played by Greek children. In Medieval history (650CE-1500CE), an era characterised by disease, children continued to play. The painting 'Children's Games' by Pieter Breughel (1560) shows over 200 children playing over 80 different games. Since the industrial revolution, professional and academic demands have increased. Urbanisation has resulted in the loss of natural environments. This means less time and space for children to play. Consequently, research now focuses on ways to get children active.

Conclusion

From an evolutionary perspective, children's play has persevered throughout history, enduring extreme conditions like war, famine, drought, and disease. Therefore, the advantages of play during childhood must outweigh the metabolic cost. Play is beneficial during childhood to imitate, practice, and develop skills for adulthood. This review understands children's play from an evolutionary perspective and has informed the design of a games-based intervention to promote PA in a fun environment.

PHYSICAL ACTIVITY DURING MENSTRUATION: ANALYSING HISTORICAL PERSPECTIVES

PAYNE, K.
UNIVERISTY OF GLASGOW

Introduction

Physical activity (PA) can be maintained during menstruation, yet a significant number of individuals avoid it, contributing to a wider issue of inadequate PA levels amongst women globally, with notable public health implications. Attitudes towards PA during menstruation are shaped by various factors, with the persistence of outdated historical beliefs likely to be a contributing factor. Understanding the origin of these assumptions is important for dispelling myths and offering inclusive PA guidance.

Methods

To investigate historical attitudes towards PA during menstruation, a research strategy was implemented that involved searching scientific databases as well as local (Scotland) library and archival sources. Relevant academic and non-academic historical texts related to women's health, PA and menstruation from 1849 to 1960 were identified. Thematic coding identified narrative themes, guiding the critical analysis.

Results

A total of 39 texts were identified. Four overarching themes were identified which gave insights into historical perspectives. The first explored historical attitudes to exercise during menstruation, while the second highlighted the conflation of exercise and study as activities deemed detrimental to women's health. The third examined recommendations of specific exercises for dysmenorrhoea and the final theme considered intergenerational propagation of menstrual taboos.

Discussion

Of 25 sources that gave specific advice on PA during menstruation, 18 encouraged its continuation, while 7 recommended complete rest. There was no discernible trend in these attitudes over the covered time period. Historical texts repeatedly linked both PA and intellectual pursuits as detrimental to women's reproductive health, discouraging engagement in such activities during menstruation. These erroneous assertions are rooted in sociocultural biases relating to women's roles and abilities, persist into the mid-twentieth century and may more subtly manifest in contemporary attitudes. Also highlighted was advice suggesting prescribed exercise routines to be undertaken before and during menstruation, aiming to alleviate dysmenorrhea. Despite being poorly researched, these routines persist in informal contemporary practices disseminated via the internet and wider media. Furthermore, historical texts repeatedly acknowledge that girls primarily receive menstrual health advice from their mothers, a route which is particularly vulnerable to misinformation and bias. This intergenerational channel of information sharing remains a prominent source of menstrual health information today so recognising and addressing the associated risks of misinformation should be given greater consideration.

This study, by revealing enduring historical attitudes impacting womens engagement in PA during menstruation, has the potential to inform public health communications and initiatives, facilitating increased adherence to current PA guidelines.

KOREAN SPORTS MEDICINE FROM THE 1980S TO THE 2020S: EXERCISE PRESCRIPTION AND HEALTHCARE MANAGEMENT IN GREY AREAS

JIN, H.

ZHEJIANG NORMAL UNIVERSITY

Introduction

The first sports medicine book written in English, Sports Medicine, was published in 1962[1]. The emergence of a new type of human, the trained athlete, enables the development of a new academic discipline. Initially targeting professional athletes, sports medicine expanded to the general population with the popularization of sports and the development of prevention and rehabilitation medicine. However, in Korea, the progress of sports medicine has been slow, despite the widespread recognition that 'exercise is medicine' and the need for rehabilitation. To comprehend the current state of therapeutic exercise and its popularization, it is important to understand the historical progression of sports medicine in society.

Method

This study traced the academic history of sports medicine based on the literature review, focusing on The Korean Journal of Sports Medicine as the primary source of analysis. Established in 1983, The Korean Journal of Sports Medicine has been a key platform for the field of sports medicine. Additional secondary sources, including academic materials, policy documents, and press releases were also utilized to provide a thick historical narrative.

Results

There were two overarching trends: Academic and institutional change. Sports medicine has emerged as a field that intersects with two disciplines: medicine and sport science. Initially, sports medicine within the realm of sport science was considered a part of the medical field, but as the field developed, most of it moved away from its roots in the medical field. Since 1995, therapeutic exercise specialists who have been trained and supported by the government have faced challenges in their expertise. They have been referred to as healthcare managers rather than sports medicine/therapeutic exercise professionals since 2015.

Discussion

Progress in sports medicine research has led to the emergence of new majors in higher education, such as exercise prescription. Despite this academic growth, therapeutic exercise professionals have faced challenges in the medical domain due to the implementation of the National Sports Promotion Act of 2014, which abolished the profession of exercise prescription. Consequently, a considerable number of certified therapeutic exercise specialists have transitioned from working in hospitals to local fitness clubs, while physiotherapists have expanded their involvement in rehabilitation interventions. Many aspects of sports medicine knowledge have been disseminated to the general public within the framework of healthcare management. This study demonstrates that sports medicine in Korea is not confined to a specific specialty but rather exists in a grey area where medicine and sports science intersect.

THE ANTECEDENT INFLUENCING FACTORS OF MEGA-EVENT ON NATIONAL IDENTITY OF HONG KONG RESIDENTS: A STUDY BASED ON THE PRE-EVENT OF THE 15 NATIONAL GAMES OF CHINA

CHEN, X., LI, S., ZHOU, L.

GUANGZHOU SPORT UNIVERSITY

Purpose – Hong Kong is a highly prosperous international metropolis and a free port, one of the worlds three major financial centers, and a significant hub for international trade and innovative technology. It is a blending place of eastern and western cultures. Studying the national identity of Hong Kong residents holds significant practical importance.Take the 15th National Games of china that the State Councils approval of Guangdong, Hong Kong and Macao to co-host as an example, this study explored the antecedent Influencing factors affecting national identity of Hong Kong residents before the 15th National Games of china.

Methods – Based on the overall framework of "Stimulus→Organism→Response" of S-O-R theory, focused on Hong Kong residents, takes social exchange theory and social identity theory as theoretical perspectives. 383 valid questionnaires were collected from Hong Kong residents by convenient sampling method. Amos 26.0 software was used to build the structural equation model, estimate (standardize), and compare the path coefficient, significance and fitting index. Hypothesis based on the research model: (a)H1: The Perception of positive outcome (POP) formed by Hong Kong residents before the 15th National Games of china will positively influence the event support (ES). (b)H2: The Perception of negative outcome (NOP) formed by Hong Kong residents before the 15th National Games of china will negatively influence ES. (c)H3: POP will positively influence national identity (NI). (d)H4: NOP will negatively influence NI. (e)H5: ES will positively influence NI.

Results and Findings – The results support all hypotheses, with POP and ES (=0.324, $p<0.001$), being positively correlated, and POP having a positive effect on NI (=0.461, $p<0.001$), supporting H1, H3, respectively. NOP on ES (=-0.239, $p<0.001$) and NOP on NI (=-0.267, $p<0.001$) both were negatively correlated, supporting H2, H4, respectively. ES on NI (=0.134, $p<0.05$), being positively correlated, supporting H5. Perception of positive outcome had positive effects on event support and national identity; Perception of negative outcome had negative effects on event support and national identity; event support had positive effects on national identity. Among them, event support are direct influences on national identity, while Perception of positive and negative outcome indirectly influences national identity through event support.

Discussion – The results revealed the relationship between Perception of positive outcome, Perception of negative outcome, event support and national identity. The findings indicate that POP significantly boost residents ES and NI, highlighting the crucial role of mega-event in enhancing national consciousness and ethnic pride. NOP have a detrimental effect on ES and NI, reflecting the impact of mega-event and social issues on NI. Additionally, there is a positive relationship between ES and NI, suggesting that ES may translate into NI. Taken together, the findings of this study highlight the significant potential of major sporting events to enhance national identity. These findings not only provide a novel perspective for the academic community, but also provide practical guidance for policy makers, sporting event organizers, and administrators on how to use sporting events as a means to promote social harmony and national identity.

Invited Symposium

IS-PN01 Physiological resilience, the 'new' determinant of endurance exercise performance: mechanisms and potential intervention

PHYSIOLOGICAL RESILIENCE: THE 'OTHER' FACTOR INFLUENCING ENDURANCE PERFORMANCE

JONES, A.

EXETER UNIVERSITY

This talk will introduce the concept of physiological resilience or durability, and highlight its importance as an independent determinant of endurance exercise performance. This can be illustrated through studies on truly elite athletes. For example, in Nike's 'Breaking 2' marathon project, measurements of VO2max, fractional utilization of VO2max and running economy in a fresh condition provided reasonably accurate predictions of performance and were used to identify which elite athletes were best equipped physiologically to attempt to break the 2-hour marathon barrier. Of the athletes selected, however, only Eliud Kipchoge has achieved this feat and his performances are exceptional compared to his peers. This suggests that he has superior resilience (i.e., is better able to resist the deterioration of his 'start-line physiology' during a marathon) compared to his rivals. Recent studies indicate that not only do physiological variables such as exercise efficiency and critical power deteriorate during prolonged, fatiguing exercise, but the extent of this deterioration is highly variable between individuals (for example, 1-32% for critical power). Moreover, in the field, the degree of uncoupling between heart rate and speed during endurance exercise has been shown to be an important metric of performance. The basis for these differences in neuromuscular fatigability and metabolic stability (including glycogen depletion, metabolite accumulation, and changes in muscle fibre recruitment) will be discussed with comparisons drawn between elite East African runners and their Caucasian counterparts.

THE MUSCLE-TENDON UNIT IN RUNNING, A MODEL OF ECONOMY/EFFICACY AND RESILIENCE

NICOL, C.

AIX-MARSEILLE UNIVERSITÉ

Endurance running is usually defined as a stretch-shortening cycle (SSC) type exercise in which most of the lower limb extensor muscles are optimally pre-activated prior to ground impact and then fully activated during the braking phase to actively resist to their stretch before shortening with rather low muscle activity. The muscle-tendon units of the lower limbs are impressive for their efficient use of the SSC to store and recoil elastic energy, but also for their resilience to the thousands of ground impacts encountered during running, with limited structural and functional defects specifically in SSC-type muscle actions. Over the last 20 years, ultrasound technology has provided new insights into both the efficient and

protective role of the tendon and the architectural gear ratio, as well as the lack of stretching of biarticular muscles. Each of these factors can be seen as contributing to the rather limited structural and functional deficits in SSC performance found after a running race. Using this technique, our Japanese colleagues have highlighted the potential role of genetic endowment in the specificity of the muscle-tendon and foot architecture of Kenyan runners. As previous physiological studies have shown no marked specificity in any of the basic physiological parameters of elite East African endurance runners, it was concluded that their particular triceps surae muscle-tendon structure may contribute to their unique muscle activation and economical running pattern, which differs from the classical SSC concept. In recent years, female participation has increased considerably in endurance running. Despite sex differences in muscle-tendon characteristics and running biomechanics, males and females do not differ in terms of running economy, suggesting that both sexes optimise their running patterns to suit their characteristics. An indirect way to study sex differences in resilience is to follow the structural and functional recovery pattern after a race. In recreational runners, females showed more structural deficits in the hamstring muscle group than males, but sex-specific intermuscular compensations occur during SSC tasks that would mask residual dysfunction of some muscles.

STRATEGIES TO IMPROVE PHYSIOLOGICAL DURABILITY AND PERFORMANCE IN ENDURANCE ATHLETES

ZANINI, M.
LOUGHBOROUGH UNIVERSITY

This talk will discuss effective interventions to enhance physiological resilience (or durability), and compare athletes with different characteristics to explore other potential mediators of this phenomenon. The current evidence on training interventions to influence resilience in trained athletes is limited, with strength training and repeated sprints proven to be effective. Specifically, adding strength training to the program of endurance athletes can improve performance at the end of prolonged exercise (by between 4 and 40%), as demonstrated in cycling, running, and cross country skiing. Together with this, a reduced deterioration of running economy or cycling efficiency often occurs. Including short sprints during prolonged exercise may be another strategy to improve performance in a fatigued state, although evidence is limited to a few cycling studies. Longitudinal and cross-sectional studies with trained and elite athletes also suggest that performance level, age, and training background can influence resilience, with higher calibre athletes, who are used to longer endurance sessions, and somewhat older athletes being able to produce superior performance after prolonged exercise, and displaying less pronounced physiological drifts. Dietary interventions can also improve durability, with carbohydrate intake allowing athletes to maintain their fresh critical power (CP) after prolonged cycling compared to placebo. Finally, resilience may be dependent on sex, with female runners demonstrating a lower deterioration of economy during prolonged runs, which may help explain differences in marathon pacing (i.e., typically more even) compared to men. Other interventions such as long runs/rides, due to their specificity, may also be effective. More studies are required to improve our understanding of adaptations leading to improvements in durability in endurance athletes.

OP-AP08 Training and Testing/Power and Strength II

NEUROMUSCULAR RESPONSES DURING TRADITIONAL AND AUTO-REGULATED RESISTANCE TRAINING

RATTALINO, L., VIEIRA, T.M., DELLO IACONO, A.
POLYTECHNIC UNIVERSITY OF TURIN

INTRODUCTION: The Autoregulation Rest Redistribution Training (ARRT) is a cluster-set resistance training method in which the resistance training structure is personalised according to an individual autoregulation target. Specifically, the number of clusters, repetitions per cluster and between-cluster rest intervals are dynamically adjusted to mitigate the within-session fatigue causing a decay of resistance training performance. While emerging evidence points to the superior performance effects of the ARRT method compared to traditional (TRA) resistance training methods, the underpinning neuromuscular fatigue mechanisms remain unexplored. Therefore, the aim of this study was to compare the effects of TRA and ARRT approaches on mechanical outputs and electromyographic responses during isokinetic contraction tasks.

METHODS: Eighteen male subjects performed two experimental sessions in a randomized order. Both sessions consisted of 24 isokinetic single-leg extension repetitions, executed in concentric mode at a speed of 60 degrees · s-1 and performed according to two training configurations; traditional (TRA): 3 sets of 8 repetitions with 120s interset rest, ARRT: a personalized combination of clusters, repetitions per cluster, and between-cluster rest regulated upon a 20% peak torque loss threshold from the first repetition. Work outputs were recorded repetition-by-repetition. Surface electromyograms (EMG) were recorded from the Vastus Medialis (VM), Rectus Femoris (RF) and Vastus Lateralis (VL) muscles, at both the proximal and distal portions. For each movement cycle, the mean frequency (MNF) of the EMG spectrum was computed according to the Choi-Williams time-frequency analysis. Then, changes in MNF across repetitions were considered to assess how prone the muscles were to fatigue: the myoelectric manifestation of muscle fatigue. The effects of TRA and ARRT on work outputs and EMG responses were investigated using linear mixed-effect and spline mixed-effects models, respectively.

RESULTS: A significant interaction between protocol and repetition was found on work loss (0.41J × repetition, $p<0.001$) indicating that TRA induced greater work loss per repetition compared to ARRT. Overall, no significant effects of training protocol were found on changes in MNF ($p=0.059$). However, a main effect of muscle was found indicating greater MNF changes in the RF compared to both VM and VL (both $p<0.001$). Finally, similar MNF responses were observed between the proximal and distal portions of the muscles ($p=0.956$).

CONCLUSION: The ARRT approach resulted in a similar myoelectric manifestation of fatigue as the TRA, indicating a comparable peripheral metabolic stress induced by TRA and ARRT. It is therefore possible the distinct mechanical outputs between the two training methods may have stemmed from neural and motivational factors.

PSYCHOPHYSIOLOGICAL EFFECTS OF MUSIC ON THE BENCH PRESS EXERCISE: ANALYSIS OF MUSCLE POWER IN A GROUP OF YOUNG ATHLETES

BOZZATO, M., RIZZATO, A., DI SILVESTRE, A., PAOLI, A., MARCOLIN, G.

UNIVERSITY OF PADUA

INTRODUCTION: Listening to music could be an encouraging way to increase adherence and enjoyment in physical activity practice. The effects of music on physical activity have been comprehensively studied (1) and showed that music could be an ergogenic aid in improving psychological and psychophysical states, besides exercise performance (2). However, previous research focused on exercises that are hardly found in everyday sport practice (e.g. handgrip tests, and isometric strength tests) (3,4). Thus, this study aimed to investigate the effects of self-selected music (SSM) and motivational music (MM) on bench press power training.

METHODS: Twenty healthy young men with at least two years of experience in resistance training participated in the study. In the first session, subjects were familiarized with the experimental settings and performed the 1-repetition maximum (1-RM) test. Then, they underwent three bench press sessions in a randomized order: with SSM, MM, and no music (NM) as a control condition. A 48-hour recovery occurred between sessions. In each session, subjects performed three sets of eight repetitions at 75% of 1-RM. We calculated the mean power (PAVG) and peak power (PPEAK) for every completed repetition. Subjects were administered the Borg scale CR-10 (RPE), the Feeling Scale (FS), and the Felt Arousal Scale (FAS) within each session. A two-way analysis of Variance (ANOVA) for repeated measures investigated the main effect of music (i.e., SSM, MM, and NM) and fatigue (i.e., first, second, and third set) or the interaction between them on the bench press power outputs (i.e., PAVG and PPEAK). Moreover, a one-way ANOVA was performed to investigate the effect of music on FAS, FS, and RPE. The level of significance was set to $p<0.05$. Bonferroni post hoc analysis was performed where appropriate.

RESULTS: A significant main effect of music ($p<0.01$) and fatigue ($p<0.01$) was found for PAVG and PPEAK. The post hoc analysis outlined higher power values only in SSM compared to NM ($p<0.05$). Moreover, PAVG and PPEAK values decreased from the first to the third set ($p<0.001$). However, when comparing the third set, SSM highlighted higher power values than NM ($p<0.01$). SSM and MM positively affected FS ($p=0.030$) and FAS ($p<0.001$) scores. Interestingly, FAS scores resulted higher in SSM with respect to MM and NM ($p<0.05$). No changes in perceived exertion were detected.

CONCLUSION: Our data highlighted improved performance during the bench press exercise when subjects listened to music. Notably, self-selected music seemed to be as effective as motivational music independently from the beats per minute (BPM). Moreover, SSM led to a higher psychophysical activation than MM. Our findings thus encourage the use of self-selected music during resistance training.

EFFECT OF TRAINING BACKGROUND AND LOAD LEVEL ON ACUTE NEUROMUSCULAR AND HORMONAL RESPONSES AND RECOVERY DURING POWER LOADINGS

KOTIKANGAS, J.1,2, WALKER, S.1,2, HÄKKINEN, K.1,2, PELTONEN, H.3,1,2

1> FACULTY OF SPORT AND HEALTH SCIENCES, UNIVERSITY OF JYVÄSKYLÄ; 2> NEUROMUSCULAR RESEARCH CENTER; 3> SPORT BUSINESS MANAGEMENT, SCHOOL OF BUSINESS, JAMK UNIVERSITY OF APPLIED SCIENCES

INTRODUCTION: Various power resistance training loadings are used to improve rapid force production during high-velocity dynamic movements [1,2]. In addition to the loading protocol, previous training background seems to affect acute responses and recovery to resistance loadings [3]. Thus, we compared the effect of two power loadings with different load levels on neuromuscular and hormonal responses and recovery in power-trained athletes (PA) and nonathletes (NA).

METHODS: PA (n=6) and NA (n=8) performed two power loadings consisting of 7 sets of 6 repetitions with 3 minutes between-set rest in Smith-machine back squat. The intensity, i.e. barbell load, was either 50% (PL50) or 75% (PL75) of the participant's one repetition maximum (1-RM). Maximal bilateral isometric force (MIVC) and rate of force development with 5-millisecond sampling window (RFD) during isometric leg press, dynamic average velocity (VEL) during back squat, and rest twitch force (RT) during isometric knee extension were measured before (PRE), during (MID) and after loadings (POST),

and after recovery of 1 (POST1), 2 (POST2), and 24 hours (POST24). Serum concentrations of growth hormone, cortisol, creatine kinase (CK), and blood lactate (BL) were measured at PRE, MID, POST and POST1.

RESULTS: Total work was significantly higher during PL75, and PA performed significantly more work than NA during both loadings (p=0.001). There were significant differences between groups in BL during PL50 (F=9.862, p=0.009, ηp2=0.473) and PL75 (F=12.535, p=0.005, ηp2=0.533) with greater increases in BL at MID (p=0.016 and p=0.003, respectively) and POST (p=0.009 and p=0.005, respectively) in PA. A trend for larger increases in CK at POST24 from PL75 was found in PA (p=0.060). Total work correlated positively with both BL and CK (r>0.830, p<0.001). A trend for between-subject effect was found for VEL during PL50 (F=4.592, p=0.057, ηp2=0.292) indicating that PA had a greater decrease in VEL at POST (p=0.045). Significant loading × time interactions were found for all measured variables (F>3.671, p<0.05, ηp2>0.220), indicating that significantly greater decreases in neuromuscular variables and increases in blood variables were observed during PL75 versus PL50 (p<0.05). All neuromuscular variables were recovered at POST24, except RFD after PL50 and RT after both loadings, which already recovered at POST2.

CONCLUSION: Training background seemed to affect mainly blood variables, whereas higher load level led to greater neuromuscular and hormonal responses. These findings may be explained by differences in absolute total work performed between groups and loadings. Load level should be selected based on the individual's training goals, as acute responses may be linked to long-term training adaptations. Moreover, recovery rates of maximal force and rapid force production should be considered in periodization, especially when selecting same-day exercise sessions.

EFFECTS OF COMBINING FREE WEIGHT WITH ELASTIC BANDS DURING UNILATERAL LEG PRESS ON MECHANICAL PERFORMANCE.

REVUELTA-LERA, B., RIAL-VAZQUEZ, J.1, NINE, I.1, FARIÑAS, J.1, RÚA-ALONSO, M.1, MARQUEZ, G.2, IGLESIAS-SOLER, E.1

1: UNIVERSITY OF A CORUÑA / Q6550005J; 2: UNIVERSITY OF A CORUÑA

INTRODUCTION: During exercises such as leg press there is an imbalance between the torque demanded by the external load and the torque-generating capacity of the muscle, resulting in a stimulus that may be suboptimal. The combined use of elastic band with free weight is a possible solution to this problem (1,2). The aim of this study was to compare 4 different bands and free weight configurations regardingmuscle performance.

METHODS: 22 healthy subjects (16 men and 6 women) with at least 6 months of continuous strength training were recruited. Each subject completed 4 sessions with different bands and free weight combination: only free weight (FW), 10%, 20% and 30% of the load provided by elastic tension.

All sessions consisted of 3 sets of deep unilateral leg press to task failure with a 12RM load and 4 minutes of rest between sets. Total number of repetitions completed (TREPS), mean and peak velocity (MV, PV) were recorded during the entire session. Percentage of velocity loss (VL) and the % of range of movement (%ROM) at which peak velocity was achieved were also calculated. Neuromuscular fatigue was assessed by the twitch interpolation technique.

To explore the effect of condition, one way ANOVA was performed. Additionally, 4x3 ANOVA was used to analyzed condition across sets.

RESULTS: A main effect of condition was detected for TREPS, PV, MV and %ROM (p≤0.034). Greater number of repetitions were completed in the 30% condition compared to 10% (p=0.015) and a tendency was observed for 30% > FW (p=0.053). PV was higher in FW compared to the other conditions and MV was greater in 30% in comparison with 10% (p=0.019). No differences between conditions were observed for VL (p=0.145).

Only a significant interaction between condition×set was observed for VM (p=0.023). VM was greater in SET2 for 30% compared to 10%. VM was higher in SET3 for 30% in comparison with FW.

CONCLUSION: Combining elastic bands with free weight seems to be an effective way to achieve a higher number of repetitions whereas replacing 30% of free weight by elastic tension allows maintaining a higher MV. These results show that elastic bands are useful for inducing changes in mechanical stimulus of resistance training (1).

OP-BM06 Motor Learning

"IN-VIVO HISTOLOGY" OF MOTOR SKILL LEARNING-INDUCED WHITE MATTER PLASTICITY IN THE HUMAN BRAIN

LEHMANN, N., AYE, N., KAUFMANN, J., HEINZE, H.J., DÜZEL, E., ZIEGLER, G., TAUBERT, M.
OTTO VON GUERICKE UNIVERSITY MAGDEBURG

INTRODUCTION: The mechanisms subserving motor learning in the intact human brain are not fully understood. We recently reported that learning a dynamic balancing task (DBT) over a 4-week period in young healthy adults (n = 24) leads to a behaviorally relevant increase in the complexity of cortical neurite orientation in motor brain areas [1], consistent with the idea of synaptic remodeling [2]. However, since a comprehensive understanding of motor learning can only be achieved by studying the interaction of distributed cortical and subcortical areas [2], we will focus here on learning-induced changes of the microstructural composition of the fiber tracts that interconnect hub regions of the motor network.

METHODS: We used a powerful within-subjects design with a 4-week life-as-usual control period immediately followed by an equally long period of DBT learning, as described in [1]. A unique set of quantitative MRI (qMRI) contrasts weighted towards diffusion, relaxation times and magnetization transfer were measured at baseline as well as before and after the learning period. Advanced biophysical models of tissue microstructure were fitted to these data, resulting in parameter maps sensitive to features such as tissue density, neurite orientation and density, myelin and iron [3,4]. White matter fiber tracts were virtually dissected using tractography and neural network-based bundle recognition [5], and qMRI parameter maps were projected onto these bundles. Finally, along-tract statistics of latent microstructural changes over time [6] were performed.

RESULTS: Non-overlapping 95% bootstrap CIs [6] of factor scores over time suggest significant learning-induced plasticity in major association (anterior thalamic radiation, superior longitudinal fascicle), commissural (corpus callosum) and projection tracts (corticospinal tract, thalamocortical and corticostriatal fibers). Importantly, based on factor loadings on the trajectory of latent change over time, we were able to infer three main drivers of neuroplastic change: process 1 is dominated by myelin-sensitive metrics, process 2 is dominated by neurite density and dispersion-sensitive metrics, process 3 is dominated by iron-sensitive metrics.

CONCLUSION: Here we have characterized the multifaceted microstructural changes in white matter in response to motor learning with unprecedented biological specificity. Consistent with theoretical predictions based on animal studies [2], we demonstrate the presence of neuronal, extra-neuronal and myelin-related changes also in the human brain. In perspective, we anticipate our study to be a starting point towards a more comprehensive understanding of the mechanisms subserving motor learning in physiological and pathological aging or in movement disorders.

IMPACT OF MASTICATORY MUSCLE MOBILIZATION AND CHEWING EXERCISES ON MUSCULAR TONE AND SOLEUS H-REFLEX RESPONSES

KALC, M., MAGDIC, M., MURKS, N., KRAMBERGER, M., HOLOBAR, A.
SCIENCE AND RESEARCH CENTRE KOPER

INTRODUCTION: The interconnected nature of human musculature and the neural system suggests that localised activities in the neck and masticatory systems could significantly impact spinal excitability throughout the body. For example, teeth occlusion, occurring voluntarily or non-voluntarily during sports activities, has an immediate facilitatory effect (1). However, the effect of stretching and relaxation of masticatory muscles is not well studied. This study aims to investigate the effects of neck and masticatory musculature mobilisation exercises, as well as specific chewing exercises, on masticatory muscle stiffness and the soleus (SOL) H reflex.

METHODS: Ten participants (age 27.2 ± 6.8 years, 4 females) engaged in two interventions: relaxing exercises for the neck and masticatory musculature (EX) and heavy chewing (CW). These interventions were separated by a 30-minute washout period. Masseter muscle tone and stiffness, as well as SOL H-reflex and D1 presynaptic inhibition, were assessed before and after each intervention using a handheld myotonometric device and a 64-channel matrix electrode (GR08MM1305, OT Bioelettronica, Italy). A bipolar version of the signal was computed to extract peak-to-peak amplitudes of electrically elicited responses (Global EMG). Additionally, signals were decomposed to analyse contributions from single motor units (2). A total of 8400 firings from 376 distinct MUs were categorised based on low, medium, and high firing thresholds. Data were analysed using repeated measures nested linear mixed-effect models.

RESULTS: The H-reflex amplitude decreased post-EX intervention, in contrast to the CW intervention, where it remained unchanged, resulting in a significant interaction effect ($p < 0.001$). No statistically significant changes were observed in D1 presynaptic inhibition ($p = 0.2$). Analysis at the single MU level reflected results consistent with the global EMG, but interventions did not selectively affect MUs of different threshold categories. Masseter muscle stiffness and tone increased post-EX and decreased post-CW, showing a significant interaction effect ($p < 0.001$).

CONCLUSION: Neck and masticatory muscle stretching and mobility exercises significantly reduced SOL H-reflex amplitude, indicating a potential global reduction in spinal excitability and enhanced relaxation. This effect does not appear to be mediated by D1 presynaptic inhibition mechanisms and could involve other spinal ionotropic and neuromodulatory mechanisms (3). In contrast, an increase in muscle tone and stiffness was observed during EX, possibly due to increased blood flow in the active muscles, while the decrease post-CW might be attributed to fatigue-induced mechanisms.

EFFECTS OF RESPONSE-OPTIMISED TRAINING ON MOTOR SKILL LEARNING AND TRANSFER

PRABHU, N.M., MATKE, M., LEHMANN, N., AYE, N., ZIEGLER, G., TAUBERT, M.

OTTO-VON-GUERICKE UNIVERSITÄT MAGDEBURG

INTRODUCTION: Positive effects of exercise on cognition are thought to be especially strong at either ends of the life span spectrum [1]. Particularly in case of older adults approaching physical and cognitive decline, optimisation of exercise induced benefits is necessary [2]. One proposed approach is to match the difficulty level of the task being trained to the individual's abilities and applying this optimised ratio during training [3]. Therefore, we hypothesized that optimal training conditions would induce higher learning gains and enhance transfer effects onto untrained motor and cognitive tasks.

METHODS: We conducted a randomized, single-blinded, 6-week dynamic balance training (DBT) intervention [4] optimised to the participants individual balance ability [3] (n=30, age range 60-80 yrs). Balance ability was assessed using 6-different levels of task difficulties ranging from level 0 (highest) to level 5 (lowest). Training was formulated to emulate either overload, underload or optimal load conditions. Cognitive (memory and executive) and near-far motor transfer (untrained variations of DBT and Wii) were investigated half-way through training duration (mid) and post training (post). Statistical analyses were conducted using repeated measures ANOVA with simultaneous component analysis (RM-ASCA+), a method combining linear mixed models with PCA [5]. Using the optimal group as the reference condition, group differences were inferred from non-overlapping 95% bootstrap intervals of the factor scores [5].

RESULTS: RM-ASCA+ revealed higher learning gains after the first training session in the optimal training group (95% CI [0.17, 1.44]) compared to both overload (95%CI [-2.46, -0.07]) and underload conditions (95%CI [-2.08, 0.03]). Similarly, higher learning gains after second (optimal vs underload: 95%CI [-1.76, 0.089]) and fifth training sessions (optimal vs overload: 95%CI [-1.83, 0.22]) were detected. This advantage of optimal training load was more pronounced at higher task difficulty levels as group differences were driven by higher factor loadings at level 1, 2 and 5. Furthermore, optimal load (95%CI [0.34, 1.01]) induced higher transfer effects mid- (underload: 95%CI [-1.29, 0.47], overload: 95%CI [-1.64, -0.3]) and post-intervention (underload: 95%CI [-1.46, -0.04], overload: 95%CI [-2.01, -0.34]). These differences were driven by higher factor loadings for motor transfer and executive tasks.

CONCLUSION: Our results show that benefits of optimising practice conditions in old age are not just limited to greater learning gains on the trained task, but are also reflected as performance improvements in transfer tasks. These findings further highlight the underlying neural mechanisms involved that enable transfer across domains.

MOTOR IMAGERY ABILITY RELATES TO IMPROVEMENTS IN FORCE CONTROL IN OLDER FEMALES

CALKINS, C., KRAEUTNER, S., JAKOBI, J.

UNIVERSITY OF BRITISH COLUMBIA OKANAGAN

INTRODUCTION: Mentally rehearsing a task with no overt movements is defined as motor imagery training (MIT), and its application can improve task performance. With increased age the ability to maintain steady force output (force steadiness) declines, and females are also less steady than males. The purpose of this study was to understand if a single session of MIT would improve force steadiness of isometric elbow flexion contractions of older and young females. It was hypothesized that MIT would improve force steadiness and increase corticospinal excitability during isometric elbow flexion contractions in older and young females. It was also hypothesized that older females would improve to a greater extent compared to young females.

METHODS: Twenty-two young (aged 19-35) and thirteen older (aged 65-90) female participants were randomly assigned to a MIT group or control group. Both groups were tested in a block order. Blocks 1,3, and 5 involved participants performing isometric elbow flexion contractions at 10% of their maximal voluntary contraction. Blocks 2 and 4 involved participants performing MIT (training group) or viewing a documentary (control group). Motor evoked potentials (MEPs) were elicited within the last 5 seconds of each submaximal contraction in blocks 1,3 and 5.

RESULTS: The MIT group were less steady than the control group in block one ($p=0.02$), and force steadiness improved in the older group with MIT in block three ($p=0.008$). There were no significant findings for MEPs ($p>0.05$). For visual ($p=0.05$) and global ($p=0.04$) motor imagery ratings from the MIT blocks, young had higher motor imagery ratings than older females. There was a significant negative relationship in older females between global ($r=-0.715$, $p=0.035$) and visual ($r=-0.773$, $p=0.021$) motor imagery ratings from block 2 and force steadiness in block 3, suggesting a higher global and visual motor imagery score was associated with increased ability to produce steady contraction in older females.

CONCLUSION: This study demonstrated that motor imagery ability is maintained with aging and MIT can improve (or preserve) force steadiness in older females.

VARIATIONS IN CORTICAL FOLDING ARE ASSOCIATED WITH ADULT BALANCE LEARNING

TAUBERT, M., ZIEGLER, G., LEHMANN, N.

UNIVERSITÄT MAGDEBURG

INTRODUCTION: Differences in genetics and environment influence motor learning. Research indicates that variations in brain anatomy are related to balance learning (Lehmann et al., 2019). We have recently shown that higher levels of cortical folding in the left premotor cortex (rostral PMd) predict steeper learning rates in a challenging balance task (Taubert et al., 2023). However, it is unclear whether this brain-behavior relationship is moderated by person-specific factors. Here we tested for moderation effects by relatively stable biological factors (body size, gender, age) or environmental variation (initial performance, regular physical activity level).

METHODS: Brain imaging (cortical curvature estimated from T1-weighted MRI images) and balance learning data (N=84) were used from Taubert et al. (2023). Learning rate and initial performance were estimated using power function (slope, intercept) fitted to individual motor performance data. Multiple regression analyses tested if binarized (median split) variables (age, body size, gender, physical activity level, initial balance performance) moderate the link between cortical folding and balance learning rate. Significance was determined using non-parametric statistics with 5000 permutations and family-wise error-corrected threshold of $p < 0.05$.

RESULTS: A significant moderation effect was found for initial performance only. Here, the positive correlation between cortical folding in right PMd and learning rate was significantly larger in participants with lower as compared to higher initial performance levels. Simple slopes showed significant correlations in the right PMd only in participants with lower initial performances, whereas folding in the left PMd was correlated in participants with both low and high initial performances.

CONCLUSION: These results support previous findings on the role of individual folding differences in balance learning (Taubert et al., 2023) and suggest early developmental influences on adult balance learning. In accordance with longitudinal studies (Taubert et al., 2010; Lehmann et al., 2023), it appears that right PMd affects stabilometer learning only at lower baseline levels, while left PMd has an impact regardless of baseline level.

IS-SH01 A critical appraisal of the potential legacy effects of Cycling World Championships on transport and recreational cycling

AN UNHOLY ALLIANCE – CYCLING'S RELATIONSHIP TO SPORT

ODDY, N.

GLASGOW SCHOOL OF ART

The relationship of cycling to sport and competition is long and binding. Cycle sport was established in the brief ascendency of the velocipede bicycle in the late 1860s and was to become almost the defining feature of cycling in the 1870s and 80s. This was the period of the high (or 'ordinary') bicycle, a machine gendered male and conceptualised around increas-

ing speed over all other considerations. In the UK of the early 1890s cycle competition on the public road had become so toxic to other road users that its own legislative bodies moved to ban it, establishing the more discreet, but equally competitive 'time trialing'. This paper is in the form of a historical overview of the relationship of cycling to competition of sport during seismic changes to the nature of the activity on the public road in the UK during the 20th century, as it went progressively down market while becoming a genuine form of utility transport, its subsequent eclipse by automobilism and its resurgence in the 21st. This paper considers the legacy of what it argues is an unholy alliance between cycling and competitive sport framed up in the gender conventions and social class structures of the 19th century which inadvertently contrived, and continues to contrive against cycling in the UK (at least) as a near universal day to day form of utility transport. It takes, as a case study in the present day, the hosting of the UCI World Cycling Championships in Glasgow in 2023 and the 'Festival of Cycling' that was created around it, as an exemplar of the current (mis)understanding of cycling that is a direct inheritance of the way cycling was conceived some 160 years earlier. Nicholas Oddy is Head of Design History & Theory at Glasgow School of Art. He is Chair of the Cycling History and Education Trust, which is responsible for the National Cycle Archive housed at the Modern Records Centre in Warwick University, UK. He has been involved with academic cycling history since giving a positioning paper on Kirkpatrick MacMillan at the First International Cycling History Conference in 1990. He was also active in founding the Cycling & Society symposia a decade later. During the 1990s and 2000s he was consultant to Phillips and Bonhams for their annual Cycling and Cycling Memorabilia sales. His most recent publication is the 'The Visual Culture of Cycling', part 7 in The Routledge Companion to Cycling (2022).

CAN HOSTING THE WORLD ROAD CYCLING CHAMPIONSHIP INSPIRE MORE PEOPLE TO PICK UP THE BIKE? EVIDENCE FROM BERGEN 2017

SOLBERG, H.A.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

Cities planning to host major sport events often expect to generate economic, infrastructural, social, and health benefits. The prospect of positive payoffs is often emphasised in applications for financial funding for the events from the public sector. A much-debated issue is to what degree such events are capable of increasing participation in sport and physical activities in the population. Organisers contend that major international sport events are catalysts for sport participation and physical activity. This research investigates the existence of such effects related to the 2017 World Road Cycling Championship that was hosted in the city of Bergen, Norway (population approx. 280,000). In the years leading up to the Championship, representatives of Bergen municipality emphasised impacts that had the character of externalities. In the application for governmental funding from the Ministry of Culture, it was argued: "The Championship will be used to stimulate and inspire more people to choose an active life-style, so that it creates several long term impacts, and in many ways…strengthen the use of cycling as a transportation mode, and hence contribute to reduce pollution." To achieve these objectives, the Championship was surrounded by campaigns and programmes to stimulate residents' motivations and attitudes toward cycling as a means of transportation and exercising. These included a: • Bicycle education programme for children (2015–2017) • Public health programme called Cycle to the World Championship (2017) • Cycling World Championship for older people (2017) • Teaching plans for schools (2016–2017). Pre- and post-event residential surveys show that the Championship had limited impact on local resident's motivation to exercise. Although some 10% of the sample reported higher cycling frequencies in the year following the Championship, this was a temporary effect that could not be traced back to the event. Neither did bicycle traffic data indicate increased cycling activities. We found that cycling frequencies were higher in the years ahead of the Championship. Also, data from National Travel Surveys for the period 2014 to 2022 shows that the modal share of cycling for daily mobility in Bergen remained stable at 3% throughout the period. This is lower than what is observed for other major cities in Norway, and, also below the national average. Taken together, the Championship was considered a big success with respect to spectator numbers and, as we reported, creating a festival atmosphere in the city but that was not enough to initiate a modification of behaviour.

EXPLORATION OF THE POTENTIAL LEGACY EFFECTS OF THE GLASGOW 2023 CYCLING WORLD CHAMPIONSHIPS USING BEHAVIOUR CHANGE THEORY

HARRINGTON, D.

UNIVERSITY OF STRATHCLYDE

Behaviour change towards cycling for transportation or recreation is complex and requires actions on multiple levels. In this symposium the author will use an auto-ethnographic approach by putting her own cycling story at the centre of her argument. She herself is a legacy product of a large cycling event – when the infamous 1998 Tour de France Grad Départ visited Ireland. The effect of seeing this spectacle in person laid latent for many years until a constellation of different actions happened to and around her. She will map her journey from rural Ireland (where she was told bicycles were dangerous) into recreational, competitive and commuter cycling onto the socio-ecological model (individual, interpersonal, community, policy). She will demonstrate the need for a systems-approach to be in place to supplement big sporting events. Actions within the system would also fit with popular behaviour change theory including those represented in the COM-B (capability, opportunity, motivation – behaviour) model. The author will then identify the campaigns and programmes that happened in Glasgow in preparation for the 2023 World Championships that may indeed set the stage for a legacy effect, but also what might be missing. Deirdre Harrington is a Senior Lecturer in Physical Activity and Health at the University of Strathclyde, Glasgow. She has over 17 years of academic research experience under her belt in Ireland, the US, England and now Scotland. During this time she has developed and evaluated studies that use physical activity in

the prevention of obesity and type 2 diabetes. She is the lead of Strathclyde's inter-disciplinary research and practice Active Mobility Hub.

CARBOHYDRATE FEEDING REPLENISHES LIVER GLYCOGEN CONTENT WELL WITHIN 6 HOURS OF POST-EXERCISE RECOVERY IN WELL-TRAINED CYCLISTS.

FUCHS, C., VEERAIAH, P., HERMANS, W.J.H., BRAUWERS, B., VONCKEN, R., PETRICK, H.L., HENDRIKS, F.K., BELS, J.L.M., VAN DEN HURK, J., WEBER, J., SENDEN, J.M., THELWALL, P.E., PROMPERS, J.J., VAN LOON, L.J.C.

MAASTRICHT UNIVERSITY

INTRODUCTION: Both liver and muscle glycogen contribute substantially to energy requirements during prolonged moderate- to high-intensity exercise. Carbohydrate intake after exercise is essential to replenish both liver and muscle glycogen stores. Consuming ample carbohydrates has shown to replenish muscle glycogen concentrations within 24 h following exhaustive cycling. Yet, the time required to replenish liver glycogen after exercise in vivo in humans remains to be determined.

METHODS: Twelve well-trained male cyclists (age: 25±5 y; VO2peak: 67±5 mL/kg/min; Wmax: 5.8±0.7 W/kg) completed two test days in a randomized cross-over fashion. On both test days, liver and muscle glycogen values were assessed before and immediately after a glycogen depleting exercise session on a cycle ergometer. This was followed by a 12-h recovery period where participants remained fasted (CON) or consumed 10 g carbohydrates per kg body mass (BM) in the form of sucrose containing beverages and carbohydrate-rich meals (CHO). Liver and muscle glycogen levels were measured again at 6 and 12 hours into recovery. We applied 13C-Magnetic Resonance Spectroscopy (13C-MRS) to quantify liver and muscle glycogen concentrations and Magnetic Resonance Imaging to measure liver and muscle volume. In addition, muscle biopsies were collected to determine muscle glycogen concentrations. A two-factor (time*treatment) repeated-measures ANOVA was performed, with significant findings being further investigated through Bonferroni post hoc tests. Muscle and liver glycogen data are expressed as percentage signal intensity from 13C-MRS, with pre-exercise values set as 100% with the other values being expressed as relative changes from pre-exercise values. Data are expressed as means ± SD.

RESULTS: Exercise significantly reduced liver glycogen to 60±12% in CON and 64±16% in CHO, and muscle glycogen to 35±8% of pre-exercise values in both CON and CHO (all $P<0.001$), with no significant differences between the CON and CHO day (liver: $P=0.488$ and muscle: $P=0.803$). Without carbohydrate intake (CON), liver glycogen levels further declined (12 h: 46±11% of pre-exercise values; $P=0.002$), while muscle glycogen levels remained unchanged (12 h: 38±9% of pre-exercise values) compared to post-exercise values ($P=0.596$). Following carbohydrate intake (CHO), liver glycogen levels increased beyond pre-exercise values well within 6 h (145±24% of pre-exercise values; $P<0.001$) with no further increase at 12 h (160±29% of pre-exercise values; $P=0.111$). Despite ample carbohydrate intake, muscle glycogen levels remained below pre-exercise values after 12 hours of post-exercise recovery (71±12% of pre-exercise values; $P<0.001$).

CONCLUSION: Carbohydrate ingestion (1.2 g/kg BM/h) during recovery from exhaustive exercise rapidly replenishes liver glycogen content well within 6 hours. Ingesting 10 g of carbohydrate per kg BM does not fully replenish muscle glycogen stores to pre-exercise values within a 12-hour recovery period.

HYDROLYSED COLLAGEN SUPPLEMENTATION AUGMENTS PATELLAR TENDON HYPERTROPHY AND RATE OF FORCE DEVELOPMENT FOLLOWING EIGHT WEEKS' RESISTANCE TRAINING IN FEMALE MASTERS FIELD HOCKEY ATHLETES

NULTY, C.1, ERSKINE, R.M.1,3

1. LIVERPOOL JOHN MOORES UNIVERSITY; 2. SOUTH EAST TECHNOLOGICAL UNIVERSITY 3. UNIVERSITY COLLEGE LONDON

INTRODUCTION: Despite a high prevalence of lower-limb soft tissue injuries in female Masters field hockey athletes [1], effective exercise and nutrition strategies to mitigate injury risk and enhance performance in this population are unknown. In young female athletes, however, body weight resistance exercise (RE) training with 30g hydrolysed collagen (HC) supplementation enhances patellar tendon (PT) stiffness (which may reduce injury risk and increase performance), although PT cross-sectional area (CSA) remained unaffected [2]. Higher intensity, eccentric RE may cause tendon hypertrophy, thus enabling a greater efficiency of force transfer from muscle to bone, thereby increasing peak rate of force development (pRFD) and athletic performance. The aim of this study was therefore to investigate the effect of HC supplementation combined with high-intensity, eccentric RE on PT CSA, muscle size, strength, power, speed and pRFD in female Masters athletes.

METHODS: Twenty-two international female premenopausal Masters field hockey athletes were randomly assigned to collagen (COL, n=10, 40±4 years, 69±5 kg) and placebo (PLA, n=12, 38±3 years, 69±9 kg) cohorts in a double-blind design, and completed a weekly supervised high-intensity flywheel squat RE session and two home-based lower-limb eccentric bodyweight RE sessions for eight weeks. Prior to each RE session, participants ingested either 30g HC (COL) or 30g maltodextrin (PLA), together with 500mg Vitamin C. Before and after the intervention, maximum voluntary force (MVF) and pRFD were assessed during an isometric mid-thigh pull using force plates. Vastus lateralis (VL) muscle thickness (MT) and

PT CSA were measured with ultrasonography. Countermovement jump (CMJ) height and 20 m sprint speed were evaluated using force plates and timing gates, respectively.

RESULTS: MVF increased from 892±366 to 1,011±420 N (P=0.020), VL MT from 21±3 to 22±3 mm (P=0.015), and sprint speed from 5.7±0.4 to 5.8±0.4 m·s-1 (P=0.011), with no group×time interactions (P>0.05), while CMJ height did not change (P=0.238). PT CSA increased in both groups (P<0.001) but COL (116±12 to 121±13 mm2) increased more than PLA (109±22 to 111±22 mm2, P=0.014). Similarly, pRFD increased post-training (P=0.002) but to a greater extent in COL (7.9±1.3 to 10.1±2.4 kN·s-1) than in PLA (8.5±3.4 to 9.1±3.4 kN·s-1, P=0.039).

CONCLUSION: Eight weeks' eccentric RE with 30g HC supplementation augments the gains in PT CSA and pRFD in international female Masters field hockey athletes. The greater PT hypertrophy in COL may have influenced the larger increase in pRFD in COL by augmenting RE-induced gains in PT stiffness.

ACUTE EFFECTS OF VARIOUS DOSES OF NITRATE-RICH BEETROOT JUICE ON HIGH-INTENSITY INTERVAL CYCLING RESPONSES IN WOMEN: A RANDOMIZED, DOUBLE-BLINDED, PLACEBO-CONTROLLED, CROSSOVER TRIAL

ZHANG, J., DAI, Z., POON, E.T., WONG, S.H.

THE CHINESE UNIVERSITY OF HONG KONG

INTRODUCTION: Nitric oxide (NO) plays a critical role in improving mitochondrial efficiency and muscle contractile efficiency during exercise and can be exogenously increased via nitrate supplementation. While numerous studies have investigated the effects of nitrate supplementation on exercise performance, most literature has focused on endurance-based exercise protocols. Meanwhile, the optimal dose of nitrate supplementation to maximize performance benefits during high-intensity interval exercise remains unclear, as previous studies have utilized a wide range of nitrate doses and predominantly recruited male participants, overlooking potential sex differences in responses to nitrate supplementation. Therefore, this study aimed to investigate the acute effects of various doses of nitrate-rich beetroot juice on the responses to high-intensity interval cycling in women.

METHODS: A double-blinded, randomized, placebo-controlled, crossover trial was conducted with 13 recreationally active young women (age = 23 ± 2 years). All participants performed interval exercise (8 × 1-min bouts of cycling at 85 % of peak power output [PPO] interspersed with 1-min active recovery at 20% of PPO) 2.5 h after consumption of the randomly assigned beetroot juice containing 0 mmol (placebo control group [PLA]), 6.45 mmol (single-dose group [SIN]), or 12.9 mmol (double-dose group [DOU]) nitrates. The heart rate (HR), blood pressure, blood lactate, blood glucose, oxygen saturation, rating of perceived exertion (RPE), and emotional arousal were assessed. All data collected during the interval exercises were analyzed using a two-way (treatment × time) repeated-measures ANOVA to explore the effect of interventions (PLA, SIN, and DOU) over time on the magnitude of each dependent variable. Statistical significance was set at $p < 0.05$.

RESULTS: Nitrate supplementation significantly altered the HR and RPE responses across the three trials. The mean HR was lower in the SIN and DOU groups than in the PLA group during both work intervals ($F[1.90, 195.78] = 7.06$, $p = .001$, $\eta_p^2 = .064$) and recovery periods ($F[2, 180] = 9.89$, $p < .001$, $\eta_p^2 = .099$), as well as across the overall protocol ($F[1.93, 374.47] = 16.90$, $p < .001$, $\eta_p^2 = .080$). The mean RPE was lower in the SIN and DOU groups than in the PLA group during recovery periods ($F[2, 180] = 10.39$, $p < .001$, $\eta_p^2 = .104$) and across the overall protocol ($F[2, 388] = 11.96$, $p < .001$, $\eta_p^2 = .058$). However, there was no significant difference in either HR or RPE between SIN and DOU on any endpoint.

CONCLUSION: Acute nitrate ingestion led to significant decreases in the mean HR and RPE during high-intensity interval cycling, but no additional benefit was observed with higher nitrate content. These findings may assist practitioners in implementing more effective nitrate supplementation strategies to enhance performance and adaptation during interval exercise.

PROLONGED FASTING ON PEAK FAT OXIDATION – DOES AGE MATTER?

TARRY, E.K.1,2, MIKKELSEN, S.S.1, D'AMBROSIO, M.3, TRANBERG, C.1, FALS, E.B.1, LUNDBY, S.M.1, DELA, F.1, SHAW, C.S.2, LARSEN, S.1,4, HELGE, J.W.1

1UNIVERSITY OF COPENHAGEN, 2DEAKIN UNIVERSITY, 3UNIVERSITY OF PISA, 4UNIVERSITY OF BIALYSTOK

INTRODUCTION: Prolonged fasting is an underutilised method to assess the mechanistic limitations of peak fat oxidation (PFO) during exercise, given it induces considerable energy deficit, reduced glucose and glycogen availability and thus subsequent adaptations facilitating fat handling. This study examined the fasting-induced changes in substrate availability and resultant alterations in fat oxidation. It was hypothesised that PFO rates would be substantially increased after a prolonged 3.5 day fast in healthy young and older individuals.

METHODS: 22 healthy, moderately trained men were recruited into two groups: young (n = 12) (26 ± 4 yrs, BMI 24.1 ± 1.9, VO2peak 53.6 ± 4.8 ml/kg/min) and older (n = 10) (63 ± 2 yrs, BMI 24.2 ± 1.2, VO2peak 42.9 ± 6.5 ml/kg/min) (mean ± SD)) and underwent 3.5 days of water-only fasting. Fasting blood samples and an incremental exercise test to determine

PFO and maximal oxygen uptake were conducted before and at the conclusion of the fasting period. Two-way, repeated measures-ANOVA were used to assess differences between groups over time.

RESULTS: Whole-body PFO increased from (0.45 ± 0.09 to 0.87 ± 0.14 g/min) and (0.41 ± 0.12 to 0.73 ± 0.15 g/min) in the young and older groups respectively, with PFO rates significantly higher after prolonged fasting in the young compared to older subjects (post-hoc: $p < 0.05$). No significant time by age interaction was observed when PFO was expressed relative to fat free mass. Rates of weight loss were similar in the young (84 ± 9 to 81 ± 9 kg) and older groups (76 ± 6 to 73 ± 6 kg). VO2peak values were significantly reduced after fasting, regardless of age (main effect; time: $p < 0.001$). As expected, older subjects had significantly lower VO2peak (main effect; age: $p < 0.001$). Similarly, RER values captured at maximal exercise capacity were significantly reduced following fasting, regardless of age (main effect; time: $p < 0.001$), and older subjects had significantly lower RER values regardless of time (main effect; age: $p < 0.01$).

CONCLUSION: Despite observed age attenuation in PFO and diminished anaerobic metabolism at maximal exercise output, prolonged fasting persists as a potent enhancer of peak fat oxidation. Further analyses of sampled blood and muscle are targeted towards elucidating the mechanisms underlying the fasting-induced adaptations associated with improved fat utilisation.

EFFECTS OF PROTEIN SUPPLEMENTATION DURING PILATES TRAINING ON BODY COMPOSITION, CORE MUSCLE ENDURANCE, AND JOINT FLEXIBILITY IN TRAINED WOMEN

KARPOUZI, C., KYPRAIOU, A., PETRIDOU, A., MOUGIOS, V.

ARISTOTLE UNIVERSITY OF THESSALONIKI

INTRODUCTION: Pilates is a popular type of exercise thanks to its comprehensive approach to physical fitness. Research has shown that Pilates training improves body composition, muscle endurance, and joint flexibility.1 Adequate protein intake is a key factor in supporting the adaptive response of skeletal muscle to exercise training.2 However, whether protein supplementation augments the adaptations to Pilates training remains unknown. Thus, the aim of this study was to investigate the effects of protein supplementation during Pilates training on body composition, core muscle endurance, and joint flexibility in trained women.

METHODS: Nineteen Pilates-trained women (31 ± 9 y) performed 10 weeks of Pilates training, with at least 2 sessions per week. Participants were randomly allocated to either a placebo (n = 10) or protein supplementation group (n = 9) in a quadruple-blinded (participants, intervention providers, investigators, and outcome assessors) design. Participants received 0.6 g of maltodextrin or whey protein/kg body weight/day, respectively. Habitual dietary intake was monitored throughout the study. Before and after the intervention, anthropometric measures (body weight, body mass index, and circumferences), body composition [through multifrequency bioelectrical impedance analysis (BIA) and full-scan dual-energy X-ray absorptiometry (DXA)], core muscle endurance (through the McGill's torso muscular endurance test battery), and joint flexibility (through the sit-and-reach test) were assessed. Data were analyzed by 2-way ANOVA (supplement x time) with repeated measures on time. Common BIA and DXA parameters (lean body mass, fat mass and their percentages) were further analyzed by Pearson's correlation analysis and paired Student's t test. Statistical significance was declared at $p < 0.05$.

RESULTS: Participants received 1.3 ± 0.3 (mean ± SD) protein/kg body weight/day from their habitual diet, with no significant difference between groups ($p = 0.551$). After 10 weeks of Pilates training, hip circumference decreased, body fat mass and percentage (by BIA) decreased, and total lean mass and percentage (by BIA) increased (all $p < 0.05$), regardless of supplementation. Trunk bone mineral content and arm lean mass (by DXA) increased with training ($p < 0.05$). The common BIA and DXA parameters were correlated (all $r > 0.8$, $p < 0.001$), although they differed significantly (all $p < 0.001$). BIA underestimated fat mass by an average 1.4 kg compared to DXA. Core muscle endurance increased by 23–48%, and joint flexibility increased by 57% (both $p < 0.05$), regardless of supplementation.

CONCLUSION: The novel finding of the present study is that, although short-term Pilates training improved body composition and performance parameters in trained women, protein supplementation that increased daily protein intake from 1.3 to 1.9 g/kg body weight did not have any effect on the measured parameters.

OP-MH10 Obesity/Weight loss

IMPACT OF A SUPERVISED EXERCISE PROGRAM AFTER BARIATRIC SURGERY ON BODY COMPOSITION, FITNESS, CARDIOMETABOLIC AND METABOLOMIC PROFILE: INSIGHTS FROM THE EFIBAR STUDY

MARTÍNEZ-ROSALES, E., LÓPEZ-SÁNCHEZ, L., HERNÁNDEZ-MARTÍNEZ, A., FERRER-MÁRQUEZ, M., VILLA-GONZÁLEZ, E., BARRANCO-RUIZ, Y., MARTÍNEZ-FORTE, S., GÓMEZ-NAVARRO, C., ACEITUNO-CUBERO, J., REYES-PADILLA, R., APARICIO-GÓMEZ, J.A., FERNÁNDEZ-ALONSO, A.M., TRISTÁN, A.I., SALMERÓN-LÓPEZ, A.M., ABREU, A.C., RODRÍGUEZ-PÉREZ, M., FERNÁNDEZ DE LAS NIEVES, I., MARTÍNEZ-TÉLLEZ, B., SORIANO-MALDONADO, A., ARTERO, E.G.

UNIVERSITY OF ALMERÍA

INTRODUCTION: Obesity is linked to various health issues, including type 2 diabetes and cardiovascular diseases. Bariatric surgery has been proposed as an effective weight reduction method. This study aimed to determine the impact of a 16-week concurrent exercise program on body composition, fitness, cardiometabolic, and metabolomic profile in participants undergoing bariatric surgery.

METHODS: Eighty individuals with severe obesity (body mass index ≥35 kg/m2) were randomized to an exercise group (n=40) or a control group (n=40) following bariatric surgery. Baseline, week 16-and 12-months post-surgery assessments included measurements of body composition (i.e., fat-free mass) using a bioimpedance device (Inbody 270). Cardiometabolic parameters, such as glucose and lipid metabolism (i.e., insulin, triglycerides...), inflammatory cytokines (i.e., TNF- α), and liver function (i.e., glomerular filtration rate), were obtained through blood serum. Nuclear magnetic resonance (NMR) spectroscopy was used to assess metabolite concentrations. Health-related fitness parameters, including cardiorespiratory fitness (VO2max), handgrip strength, 30-second chair stand, and back-scratch tests, were also measured at the specified time points. The exercise program consisted of 48 sessions (three times per week over 16 weeks) of 60-min sessions that include (1) warm up at 50–65% of HR reserve (HRR), (2) compensatory training (i.e., core stability and stabilizer muscle exercises), (3) strength training (whole-body exercises progressing from 1 to 3 sets, from 12 to 6 repetitions per set, from 24 to 10 repetitions maximum (RM) (≈50 to 75% of 1RM), (4) aerobic training (on a treadmill, progressing from 15 to 25 min, from 65 to 85% of HRR), and (5) cool down. Analyses were conducted using a per-protocol approach, with statistical significance set at $p < 0.05$, and R software (v. 4.2).

RESULTS: Both groups improved body composition and fitness parameters at week 16 and 12 months. However, no significant between-group differences were observed. Related to liver function, the variable glomerular filtration rate (mL/min) showed a significant between-group difference at 12 months (-4.7 mL/min, (95% Confidence Interval [CI]) 95%CI [-8.7 to -0.7], $p < 0.05$) but not at 16 weeks. We observed that 38% of the metabolites exhibited a significant reduction, but non-significant group or group x time interactions were reported. Results were consistent across sensitivity analyses.

CONCLUSION: Our study provides insights into the impact of a 16-week concurrent exercise program on individuals undergoing bariatric surgery for severe obesity. However, the complex interplay of exercise, surgery, and metabolic responses warrants ongoing investigation for a more comprehensive understanding and optimization of health outcomes in individuals with severe obesity.

THE EFFECT OF EXERCISE TRAINING REGIMENS ON BODY COMPOSITION AND CARDIOMETABOLIC HEALTH AFTER METABOLIC BARIATRIC SURGERY: THE POWER BARIATRIC RANDOMIZED CONTROLLED TRIAL.

GOLDENSHLUGER, A., SAKRAN, N., FRIDMAN, L., DICKER, D., RAZIEL, O., KAIS, H., TURJEMAN, T., YAVETZ, R., GOITEIN, D., DUVNOV-RAZ, G., MHALER, I., YUNGSTER, Y., BEN ARI, A., KEIDAR, A., GEPNER, Y.

TEL AVIV UNIVERSITY

INTRODUCTION: Metabolic bariatric surgery (MBS) is the most effective treatment for morbid obesity, yet the impact of exercise training regimens on body composition and cardiometabolic changes post-MBS remains largely unexplored.

METHODS: A six-month randomized controlled trial was conducted with participants randomly allocated to exercise training intervention groups: aerobic (n=13), strength (n=11) or combined (n=10) exercise, and a control group (n=11) receiving routine care. The supervised exercise intervention gradually increased to 3 sessions/week for six months after MBS. Pre- and post-intervention participants were assessed for changes in body composition using Dual-x-ray absorptiometry (DEXA), abdominal adipose tissue distribution by 3-Tesla magnetic resonance imaging (MRI), cardiometabolic blood markers and body function and strength through handgrip, six-minute walk test, sit to stand and one repetition maximum test (1RM).

RESULTS: In our preliminary results among 45 participants (aged 39.2+9.4y, 75.6% females, BMI 42.3+4.2kg/m2) mean weight loss was 31.7+8.8 kg, and 67.8+16.6% of excess weight loss percentage. Fat mass decreased by -10.6+4.6% ($p>0.001$) and fat-free mass (FFM) by 6.2+2.8 Kg ($p<0.001$). Following six months of intervention, the combined and the aerobic groups achieved greater preservation of FFM compared to the control group (-4.6+1.8, -4.59+1.67 vs. -8.67+2.3kg, respectively; $p<0.05$). Additionally, no significant differences were observed between the combined and strength groups regarding FFM preservation. There was a trend for a higher reduction in deep subcutaneous adipose tissue (DSAT) in the aerobic group compared to the control group (relative percentage change -35.8+15.4% vs. -16.3+12.8%, $p=0.061$). Additionally, the aerobic group showed a higher decrease in alanine aminotransferase levels com-

pared to the control group (-39.1 +25.6% vs. 4.7+33.6% respectively, p<0.05). The physical activity regime was independently associated with the change in blood glucose levels after controlling for FFM loss (β=0.426, p=0.046). Physical function improved across all groups with the most notable enhancement in the aerobic and combined groups.

CONCLUSION: This study underscores the beneficial impact of exercise interventions after MBS on muscle mass preservation, adipose tissue distribution and metabolic markers, emphasizing the importance of exercise in comprehensive obesity management.

THE EFFECT OF EXERCISE TRAINING ON RESTING METABOLIC RATE AND BODY COMPOSITION FOLLOWING BARIATRIC SURGERY; SIX-MONTH RANDOMIZED CLINICAL TRIAL

FRIEDMAN, L., GOLDENSHLUGER, A., TURJEMAN, T., SAKRAN, N., DICKER, D., KAIS, H., GOITEIN, D., KEIDAR, A., DUVNOV-RAZ, G., MHALER, I., APTERMAN, A., ISRAEL, I., GEPNER, Y.

TEL AVIV UNIVERSITY

INTRODUCTION: Approximately 50% of individuals experience weight regain within five years following bariatric surgery (BS). This is primarily attributed to decreased resting metabolic rate (RMR), driven by fat-free mass (FFM) loss post-BS. This study aimed to investigate the impact of exercise training on RMR and examine the association between changes in RMR and body composition after BS.

METHODS: Sixty candidates (39.2±10.7y, 114.3±17.5kg, 41.7±4.4kg/m2) for BS were enrolled in a six-month open-label randomized controlled clinical trial. Participants were randomly assigned to one of four groups: control group (receiving standard care), aerobic, resistance, or combined online supervised training. Training sessions gradually increase to 60 minutes/session, 3 times/week. Pre- and post-intervention RMR measured by indirect calorimetry and body composition (FFM and fat mass) measured by dual-energy X-ray.

RESULTS: The 38 participants (aerobic; n=11, strength; n=10, combined; n=11, control; n=6) that completed the study by February 2024, demonstrated a significant (p<0.01) decrease in body weight (-31.1±8.7 kg), FFM (-6.61± 2.6 kg), fat mass (-24.4±7.4 kg), and absolute-RMR (-397± 264kcal/day). Yet, all study groups demonstrated similar and significant (p<0.01) increase in RMR adjusted to body weight (2.09±2.58 kcal/kg/day). The aerobic group displayed a significant correlation between FFM loss and absolute RMR six months post-surgery (r=0.646, p<0.05). In the combined group, RMR changes were associated with both weight loss (r=0.698, p=0.01) and fat mass loss (r=0.751, p=0.01).

CONCLUSION: Relative to body weight, RMR increased following BS with or without exercise training. Despite the notable loss of FFM, the decline in absolute RMR values following BS may not necessarily signify future weight regain.

EFFECT OF FATMAX COMBINED WITH KAATSU TRAINING ON BODY COMPOSITION AND LIPID METABOLISM OF RECESSIVE OBESE WOMEN

ZHANG, P.

BEIJING SPORT UNIVERSITY

INTRODUCTION: In recent years, the recessive obesity has become one of the most easily ignored health problems, among which recessive obesity in females is the more prominent. Based on the similarities between the response mechanism of maximal fat oxidation intensity in exercise and the body response mechanism caused by blood flow restriction(BFR), this paper probes into the effect of maximal fat oxidation intensity exercise combined with BFR on the improvement of body composition and blood lipids in recessive obese women, to provide a new idea of saving time for effective fat reduction, improve their health status and quality of life, and reduce the risk of cardiovascular diseases.

METHODS: After recruitment and screening, thirty recessive obese women(20.8±2.4yrs) participated in the study that was approved by IRB at Beijing Sport University. They were randomly divided into three groups, the maximal fat oxidation intensity exercise(FATmax), the maximal fat oxidation intensity exercise union together with BFR(FATmaxBFR) and the control(CON) groups. Baseline indicators were measured for all participants, including body morphology, body composition(DXA), fasting blood lipids, and VO2max. The FATmax group carried out 50min of personalized FATmax exercise intervention, the FATmaxBFR group carried out 30min of personalized FATmax exercise intervention under the condition of wearing BFR equipment; the CON group did not carry out any exercise intervention. The exercise intervention cycle is eight weeks, four times a week, and the exercise mode is walking and running on the treadmill.

RESULTS: (1) After intervention, participants in FATmax group had significant reductions in the body weight(3.16±1.54kg), BMI(1.19±0.60kg/m2) and body fat percentage(1.68±1.53%) compared to before intervention(P<0.01). There was no significant difference in changes of body weight, BMI and percentage of body fat after intervention compared to before intervention in FATmaxBFR group. (2) The FATmax group demonstrated significantly decreased systolic blood pressure compared to before intervention(6.80±6.68mmHg, P<0.05), and the decrease of systolic blood pressure in FATmax group was significantly greater than that in FATmaxBFR group(P<0.05). There was no significant change in blood pressure in FATmaxBFR group. (3) After intervention, participants in FATmaxBFR group had significant declines in level of serum triglyceride(0.46±0.61mmol/L, P<0.05). There was no significant change in blood lipid indicators in FATmax group.

CONCLUSION: Eight-week maximal fat oxidation intensity exercise can effectively reduce body fat and improve body composition of recessive obese women, and reduce the systolic blood pressure of quiet state. The exercise mode of eight -week maximal fat oxidation intensity combined with KAATSU training failed to diminish the body fat of recessive obese women within the limited time of 30 minutes, but could effectively reduce the level of serum triglyceride under this condition.

INTERMITTENT FASTING PREVENTS GLOMERULAR MORPHOLOGICAL CHANGES IN HIGH-FAT DIET MICE

YUAN, L.
TSINGHUA UNIVERSITY

INTRODUCTION: Obesity is a global epidemic phenomenon and can be accompanied by renal dysfunction or accelerating kidney diseases [1]. However, obesity-related kidney disease is easily ignored compared to diabetes, and hypertension-related kidney disease. Concurrently, intermittent fasting (IF) has greatly popular in weight loss due to its convenience of not requiring individuals to count calories and its ability to improve metabolic diseases [2]. Thus, we hypothesized that intermittent fasting could effectively prevent obesity-related renal dysfunction.

METHODS: C57BL/6 mice were randomly divided into three groups (n=7 per group): control group (Con, chow diet), high-fat diet group (HFD, high-fat diet), intermittent fasting group (HFD+IF, high-fat diet). Mice in the Con and HFD groups were free access to food for 21 weeks. Mice in the HFD+IF group were free access to food for 13 weeks and then started IF for 8 weeks. At the end of the 21-week duration, we tested serum total cholesterol (TC), serum free fatty acid (FFA), glomerular area (GA), and circumference (GC) in all mice.

RESULTS: (1) Compared to the Con group (TC: 1.93 ± 0.51; FFA: 153.75 ± 7.85; GA: 3286.86 ± 396.23; GC: 216.22 ± 13.19) the HFD group significantly increased TC ($p<0.001$), FFA ($p<0.001$), GA ($p<0.001$) and GC ($p<0.001$). (2) Compared to the HFD group (TC: 4.06 ± 0.58; FFA: 182.41 ± 6.49; GA: 5022.29 ± 534.80; GC: 265.80 ± 11.84), the HFD+IF group significantly decreased TC ($p<0.001$), FFA ($p=0.001$), GA ($p<0.001$) and GC ($p<0.001$).

CONCLUSION: As hypothesized, high-fat diet–induced obesity mice were coincident with enlargement of the glomerular area and circumference, but intermittent fasting could prevent and improve it.

OP-BM10 Muscle Architecture

AGE-RELATED DIFFERENCES IN ARCHITECTURE USING ULTRASOUND IMAGING DURING LOW RAMP ISOMETRIC CONTRACTION

BRUSCO, C.M., CARBONARO, M., MARTINO, G., LAURETANI, F., PORCELLI, S., BOTTER, A., FRANCHI, M.
UNIVERSITÀ DEGLI STUDI DI PADOVA

INTRODUCTION: The capacity of a muscle to produce force to move the human body is significantly affected by the aging process. Alongside the decline in neuromuscular function, structural changes in muscle architecture and in the morphology of the contractile and non-contractile tissues also occur with aging, which might in turn affect force capacity [1,2]. Namely, when contracted, pennate muscles change in fascicle length and angle [3], hence the absolute decrease in fascicle length and fascicle pennation angle with age [4] might also impact relative fascicle behave during contraction. In addition, aging muscles present greater muscle stiffness. As intramuscular connective tissue has a key role in maintaining the structural integrity of the muscle, these alterations might also impact how connective tissue and muscle stiffness will influence muscle shape changes during contraction [5]. In this study we analyzed age differences in fascicle behavior during ramped isometric knee extension.

METHODS: In this preliminary analyses of an ongoing study, data of five (E) elderly (76 ±4 years) and five young (Y) adults (26±2 years) were analysed. Ultrasound imaging of the vastus lateralis (VL) was recorded during isometric ramp contractions up to 30% and 50% of the maximum voluntary contraction (MVC) with slow force increase (2% MVC/s). The probe was placed longitudinally and the recording was synchronized to the force trace. Changes in fascicle behaviour (fascicle length- Lf, fascicle angle- FA, and muscle thickness- MT) were compared from the beginning of the force contractions to 10, 20 and 30% of MVC.

RESULTS: Paired sample t-tests did not reveal significant differences between E and Y were observed for Lf, FA and MT at any time point ($p>0.05$). In the E group, significant decrease in muscle thickness was observed between the beginning of the contraction to 10 ($p=0.02$), 20 ($p=0.01$) and 30% ($p<0.01$) of MVC, whereas no significant differences were detected in Lf and FA. In the Y group, no significant differences were detected in Lf, FA and MT from the beginning of the contraction to the different time points.

CONCLUSION: Although preliminary, the change in muscle morphology, as described by the decrease in muscle thickness with increased contraction levels observed in the elderly, might indicate alterations of the contractile and non-contractile tissue interfering in muscle behaviour.

NOVEL INSIGHTS INTO BICEPS FEMORIS LONG HEAD FASCICLES CHARACTERISTICS USING DTI TRACTOGRAPHY.

MANTECON TAGARRO, C.J., TAKAHASHI, K., TOMARI, K., SHIOTANI, H., MAAS, H., KAWAKAMI, Y.
WASEDA UNIVERSITY

INTRODUCTION: The Biceps Femoris Long Head (BFlh) has a high injury risk due to its complex architecture, with an intramuscular aponeurosis (IntApo) where fascicles from each region (e.g. proximal, middle and distal) attach. Previous studies using ultrasound (US) methodology have primarily assessed fascicle length (FL) differences among these regions, however, the interindividual variation between regions remains unclear. Additionally, fascicles are often assumed as straight-line (e.g. running in a single plane) (1). Novel techniques like Diffusion Tensor Imaging (DTI) enable tracking of fascicles and the observation of their orientation changes and curvature. While DTI has been applied effectively to muscles like the Medial Gastrocnemius (2), its application to the BFlh remains largely unexplored. This study aims to employ DTI analysis to observe fascicle characteristics between different regions of the BFlh.

METHODS: Eight healthy subjects (four males and four females, 24.7 ± 2.3 years, 167.5 ± 7.2 cm, 62.8 ± 10.8 kg), without lower extremity injuries in the past year, participated in this study. Magnetic Resonance diffusion tensor imaging scans were taken with the subjects positioned prone and knee fully extended. Prior to imaging, subjects lay prone for 20 minutes to mitigate fluid content shifts, followed by pre-conditioning trials 50% MVC of knee flexion for five seconds. Segmentation of the BFlh muscle and IntApo was conducted utilizing 3DSlicer software, and tractography was performed by dsi_studio software. Fascicles attaching to the IntApo and intersecting at 30%, 50% and 70% of aponeurosis lengths (e.g. proximal, middle and distal regions) were selected. FL was defined as the length between muscle surface to the IntApo and calculated by multiplying the number of coordinates within the fascicle by the distance between these coordinates. Fascicle curvature (FC) was expressed as the ratio of its length to the straight-line distance between its endpoints.

RESULTS: No significant changes in FL (proximal: 113.03 ±17.455 (95% CI [95.575 – 130.485]) , middle: 117.80 ±15.938 (95% CI [101.862 – 133.738]) , distal: 112.11 ±13.845 (95% CI [98.265 – 125.955])) or FC (proximal: 2.76 ±0.194 (CI 95% [2.566 – 2.954]), middle: 2.78 ±0.249 (CI 95% [2.531 – 3.029]) , distal: 2.92 ±0.284 (CI 95% [2.636 – 3.204])) were observed within regions. However, fascicles were shown to change its orientation along its length, elucidating that the fascicles run in the sagittal and coronal planes.

CONCLUSION: DTI tractography allows to observe differences in FL and FC between regions of the BFlh. Additionally, it demonstrated that BFlh runs along the sagittal and coronal planes rather than just a single plane, which can lead to measurement errors when measuring FL using two-dimensional US methods.

INDIVIDUAL DISTRIBUTION OF MUSCLE HYPERTROPHY AMONG HAMSTRING HEADS: ADDING MUSCLE VOLUME WHERE YOU WANT IS NOT SO SIMPLE

FROUIN, A., LE SANT, G., BARBIER, L., JACQUEMIN, E., MCNAIR, P., ELLIS, R., NORDEZ, A., LACOURPAILLE, L.
NANTES UNIVERSITY

INTRODUCTION: The hamstring muscles play an important role in many sports, and hamstring muscle strengthening is needed to improve performance and prevent injuries (1). Hamstring strengthening programs are commonly composed of hip extension-oriented (e.g., stiff-leg deadlift) and/or knee flexion-oriented (e.g., leg curl) exercises. It is well known that a similar magnitude of muscle hypertrophy can be achieved across a wide spectrum of loading ranges from 30% to 80% of 1-RM. In recent years, low load training has been combined with blood flow restriction (BFR) to promote muscle hypertrophy (2) and enhance strength (3). However, the effect of such loading combined with blood flow restriction on the distribution of hypertrophy within the hamstring muscle group has not been investigated.

METHODS: A parallel randomized controlled trial design was implemented to compare the effect of a nine-week of High Load (HL) or Low Load-Blood flow restriction (LL-BFR) resistance training on the distribution of hamstring muscle hypertrophy. Participants were randomly allocated to one of three groups: HL, LL-BFR and control (CON). Two training sessions were composed of (a) stiff-leg deadlift and front squat and (b) a bi-set of bilateral seated leg curl and seated leg extension. They were alternated over the duration of the training program. Muscle volumes were assessed the week before and after the training program with freehand 3D ultrasound (3DUS) measurements (4).

RESULTS: Notable hypertrophy was observed for the ST (+26.5%) and SM (+17.1%) (all P values <0.01) during HL, while no changes were found for BF (+4.0%; P=1.0). LL-BFR group exhibited significant hypertrophy for SM (+21.6%), BF (+14.6%) and ST (+12.2%) (all P values <0.01).

CONCLUSION: Although LL-BFR and HL improved hamstring muscle volume to a similar extent, its distribution differed between SM, ST and BF. The hypertrophy was most in ST and SM for the HL group while it was balanced across all muscles for the BFR-LL group, the magnitude of which varied greatly among participants. These results provide new findings for optimizing training, prevention, and rehabilitation programs that aim to induce a selective hypertrophy among the hamstring muscles.

TAKING INTO ACCOUNT FASCICLE CURVATURE DURING CONTRACTION AFFECTS MUSCLE ARCHITECTURE CHARACTERIZATION

BIZET, B., TRINCHI, M., MAGRIS, R., MONTE, A., ZAMPARO, P.
UNIVERSITÀ DI VERONA

INTRODUCTION: At rest, ultrasound imaging most reliable way to analyze muscle architecture is the extended field of view (Franchi et al., 2020). This method could not be applied in dynamic conditions, where muscle architecture characterization usually involves 'best fitting' of fascicles and aponeurosis in the field of view (FOV) and a linear extrapolation of both fascicles and aponeurosis outside the FOV. This method can easily be automated, thus reducing the time required for data analysis. Although most fascicles run as a "straight lines" from the proximal to the distal aponeuroses (Narici et al., 1996), fascicles could present a curvilinear path (even at rest) in different regions within a pennate muscle) (Blazevich et al., 2006); in these conditions, automated linear extrapolation could be biased. The aim of this study was to propose and test a new semi-automatic software for tracking "curvilinear fascicles" during dynamic muscle shape changes.

METHODS: 12 healthy adults performed a maximal knee extension at 75°.s-1 on an isokinetic dynamometer. Vastus lateralis ultrasound data were collected in correspondence of the 1st (proximal) and 2nd third (distal) of the thigh by means of a linear array probe (6 cm). B-mode videos were analyzed during the isokinetic phase: i) by using the automated software "ultratrack" (linear extrapolation within and outside the FOV) (Farris & Lichtwark, 2016); ii) by using a new semi-automatic software programmed in Matlab (MLE: manual linear extrapolation). With this software, the visible part of the fascicle was divided into 4 (MLE4) or 2 (MLE2) segments (to take into account the visible curvature) whereas fascicles and aponeurosis outside the FOV were linearly extrapolated (as in the case of the "ultratrack" software). The analysed parameters were: fascicle length (FL), pennation angle (PA), muscle thickness (Th), and belly length (BL). Moreover, one video was analyzed 3 times by the same investigator using MLE4 to perform ICC reliability tests.

RESULTS: Ultratrack showed higher FL, BL, and Th values and lower PA values compared to MLE4 and MLE2 (about 20% in the proximal and 40% in the distal regions). On the other hand, no significant differences were observed between MLE4 and MLE2 analysis in each of the investigated parameters. Excellent to good absolute concordance, using the 2 factors random model with "single rate" for FL, PA, BL, and Th was found (ICC=0.93; 0.90; 0.93; 0.88 respectively; P<0.001).

CONCLUSION: Failing to consider the curvilinear behavior in fascicles with significant curvature, as in the distal region of the vastus lateralis, can result in either overestimation or underestimation of muscle geometry. It appears that MLE analysis with a visible fascicle divided into 2 or 4 segments does not affect muscle geometry evaluation.

OP-BM19 Paediatric and applied biomechanics

ANALYSIS OF ANKLE JOINT MOTION IN LAYUP PERFORMANCE DURING A YOUTH BASKETBALL GAME.

CAMPANA BONILLA, M.V.
BEIJING SPORT UNIVERSITY

INTRODUCTION: The action of the ankle joint in a layup shot is crucial for youth players in a competition. Studies showed that angles of ankle joints inversion and dorsiflexion influence layup performance. Ankle joint angles and the muscles involved in ankle joint plantar flexion participate in the layup technique. The performance of layups requires a variable effect of acceleration, this happens as a consequence of high-intensity actions in the match. Therefore, these variables may be useful for understanding and estimating ankle joint movement demands in matches with young players. The objective of this study is to analyze the ankle joint angles and acceleration in layup performance in a youth basketball match.

METHODS: Six male youth basketball athletes (15.50 ± 1.05 years, 179.17 ± 8.18 cm, 73.08 ± 20.27 kg) participated in this study. The participants signed a parent informed consent and the Research Review Board of the institution approved this study. Two portable Witmotion sensors (Serial WT9011DCL-BT Bluetooth 5.0 AHRS IMU sensor 3 axes with an acceleration measurement range of 16g/s2 and a sampling rate of 20 Hz) were attached at the lateral malleolus of the participant's right and left ankles joint. The protocol consisted during the resting time of their basketball game, each subject was instructed to stand at the three-point line, after the signal of a whistle, the subject performed one layup with their dominant hand using maximum effort. Tri-axial acceleration X, Y, Z (ACCX, ACCY, ACCZ) and angles X, Y, and Z (ANGX, ANGY, ANGZ) data were collected respectively, one-way with repeated measures ANOVA and Friedman tests were used to compare the differences, significant levels were set at $p \leq 0.05$.

RESULTS: The results show significant differences in ankle joint acceleration: ACCY ($p < 0.001$) and ACCZ ($p = 0.013$), and there were no significant results in ACCX between the subjects. Meanwhile, within-subjects effects showed significant levels in ankle joint angles: ANGX ($p < 0.001$), ANGY ($p = 0.008$), and ANGZ ($p = 0.021$) subsequently. In addition, the results

obtained from the Friedman test showed significant differences between the subjects in ACCZ, ANGX, and ANGZ ($p < 0.001$).

CONCLUSION: This study analyzed the ankle joint motion in a layup during a youth basketball match. The results demonstrated substantial variations of ACCY and ACCZ in the left and right ankle movements that would influence layup performance. Furthermore, left and right ankle motion showed predominant changes in ankle angle during the layup technique between all the participants. These findings revealed that ankle angle and acceleration variations suggest a more detailed analysis of different technique levels during a high-intensity action in basketball. The estimation of acceleration and angles in this research could be a reference applicable during youth basketball matches. Moreover, the use of portable sensors might support in-field feedback for coaches and athletes.

INFLUENCE OF TENNIS SCALING ON ACTIVATION PATTERN AND VIBRATION IN CHILDREN DURING A FOREHAND STROKE

HAUTIER, C., LE SOLLIEC, T., ZHANG, Q., GASSIER, R., GILBERT, B., TRAMA, R.

UNIVERSITÉ CLAUDE BERNARD LYON 1

INTRODUCTION: By adapting the characteristics of sports equipment to childrens physical development, sports movements can be performed more successfully and with more desirable movement patterns (1). This also allows mechanical constraints to be adapted to the childs physical abilities. That way, the International Tennis Federation has proposed the "Play and Stay" method to make tennis more accessible to all children. However, studies have yet to look at the influence of these adaptations on the muscular and vibratory stresses experienced by young tennis players. This study aimed to evaluate the vibrations and muscle activation patterns in children aged 5 to 13 performing a flat forehand following the ITF recommendations.

METHODS: Sixty junior tennis players were separated into four groups of fifteen players (Yellow, Green, Orange, and Red). Two triaxial accelerometers were taped to the back of the participants dominant hand and the rackets throat to capture the vibration signal. Also, eight surface electromyographic (EMG) sensors were fixed on arm muscles, including the Pectoralis Major, Upper Trapezius, Deltoideus Anterior, Deltoideus Medius, Biceps Brachii, Triceps brachii, Flexor Carpi, and Extensor Carpi. After a standardized warm-up, players were instructed to perform maximal isometric voluntary contractions for each muscle group, followed by fifteen maximal forehands flat. Statistical nonparametric Mapping (SnPM) analysis was used to perform statistical inferences on the EMG and vibration parameters obtained from the continuous wavelet transform.

RESULTS: No significant differences were found for EMG activation patterns. The total magnitude of vibration increased significantly from the red to the yellow category for the racket (from 1051.7 ± 362.2 to 2691.2 ± 783.8 UA, $p < 0.05$) and hand (from 526.8 ± 241.9 to 1334.4 ± 530.2 UA, $p < 0.05$). The median frequency of the hand increased between the red and yellow categories (from 158.7 ± 15.0 to 168.3 ± 15.6 Hz, $p < 0.05$), whereas it followed the opposite trend for the racket (from 206.2 ± 36.0 to 190.4 ± 26.6 Hz, $p < 0.05$). The damping time for racket vibrations did not differ between the four categories but was significantly higher in the orange group for hand vibrations.

CONCLUSION: Analysis of the various EMG parameters shows that the Play and Stay method enables children to produce an adapted activation pattern that suggests a progression in performance without any drastic change in technique during growth. The vibrations show that the vibratory stress tends to increase in proportion to the speed of the ball but that the damping time is relatively stable during growth.

HOW PERFORMANCE OF THE SPINNING HEEL KICK CHANGES AS ATHLETES MATURE?

OSULLIVAN, D.M., PROCK, M.

SEOUL NATIONAL UNIVERSITY, PUSAN NATIONAL UNIVERSITY

INTRODUCTION: The spinning heel kick is a kick in Taekwondo competition that can be awarded up to 6 points, if it knocks the opponent down. As a result of high potential reward and increase in points allocation, we can observe the spinning heel kick more frequently used in competitions and training. Therefore, the purpose of this study was to investigate how the spinning heel kick's performance related factors altered as an athlete matures from an elite level junior high-school to university level athlete.

METHODS: A total of 48 male taekwondo elite level athletes; 16 middle school, 16 high school, and 16 university, participated. After a taekwondo specific warm up the athletes performed the spinning heel kick a total of 10 times each, under the supervision of their coach and the researchers. While kicking their kinematics was recorded using motion capture system and 2 force plates. The following variables were calculated; total performance time, execution time, preparation time, the width of kicking path mediolaterally, and the maximum kicking foot speed. One way ANOVA was carried out to investigate if there were significant differences between the groups, school level, with Cohen's d calculated as the effect size.

RESULTS: The mean time to perform the spinning hook kick was 0.78 ± 0.06 s for middle school, 0.73 ± 0.06 s for high school and 0.74 ± 0.07s for university athletes. ANOVA revealed no significant differences in performance time among age groups. Likewise, no between group differences were found for preparation time. When comparing the execution time of the spinning hook kick, we found a significant between groups. Post-hoc tests revealed significant differences

between middle and high school, and between middle school and university. No differences in execution time were found. The mediolateral width of the kicking path showed no difference. Maximal kicking speed increased with the participants age and was highest for university athletes 10.56 ± 0.95 m/s, followed by high school 9.55 ± 0.80 m/s and middle school athletes 8.30 ± 1.10 m/s. The differences in maximum kicking speed were significant between groups with Post-hoc tests revealing differences between middle vs. high, middle vs. university, and high vs. university.

CONCLUSION: This study revealed age related performance differences in the spinning hook kick, with decreasing execution time of the kick and increased maximum kicking speed as the age of participants increased. However, these differences cannot be explained by differences in the preparation of the kick, as the time from the first initiation of the kicking movement until the kicking leg leaves the ground was not affected by age. Also, we found no differences in mediolateral kicking width that might explain differences in execution time and maximum kicking speed due to differences in kicking technique. Future research is therefore needed to identify the reasons leading to the age-related differences found.

INCIDENCE AND MAGNITUDE OF HEAD ACCELERATION EVENTS EXPERIENCED BY FEMALE ADOLESCENT RUGBY PLAYERS ACROSS A SEASON OF RUGBY PARTICIPATION.

SPRIGGS, N., HAMLIN, M.J., HENLEY, S., STITT, D., KABALIUK, N., SWALE, A., MELZER, T., CLARK, A., ANDERSON, T., SNELL, D., HOLDSWORTH, S., ALEXANDER, K., BASU, A., MASTERS, R., DRAPER, N.

LINCOLN UNIVERSITY, NEW ZEALAND

INTRODUCTION: There is growing concern in regard to rugby union player safety and ongoing medical problems following a concussion or long-term participation in the game. Because of the nature of rugby, players are exposed to repeated head acceleration events (HAE), potentially resulting in a concussion. These HAE can be direct (e.g. head-to-head contact) or indirect (e.g. whiplash from a tackle at the waist) and can be measured through Peak Linear Acceleration (PLA; g) and Peak Rotational Acceleration (PRA; rads/s^2) using instrumented mouthguards. Research on females and adolescent rugby players is sparse, yet they are a growing cohort wanting to play the game. It is also reported that adolescent females are at greater concussion risk and may experience concussions at a lower HAE threshold, compared to male and adult female players. Investigation of sex- and age-specific HAE magnitude and incidence is required for improving the safety of female adolescent rugby players and increase our understanding of how HAEs affect ongoing brain health.

METHODS: Eighteen female rugby players aged 12-17 years, wore an instrumented mouthguard (HIT IQ Nexus) for all school and club games and contact trainings during the 2022 rugby season in New Zealand. All HAE above 8g were recorded by the instrumented mouthguard. All sessions were recorded to verify all mouthguard detected HAE. The total amount of data collected over the season was 708.5 rugby player hours (game 266.5; training 442).

RESULTS: We found 1074 video-verified HAEs. Approximately half of these events (n = 548) were from direct head contact and 526 indirect impacts events not associated with head contact. Average impact per 1-hr of game exposure was 3.2 +/- 2.1 (mean +/- SD) and 1-hr of training exposure was 0.3 +/- 0.1. Although average impact incidence was significantly higher in games (p= <0.01) compared to trainings, game and training HAE magnitudes were not significantly different for PLA (p=0.81) or PRA (p=0.37). Games had an average PLA of 19.8 +/- 4.4 g, PRA of 1634 +/- 1372 rads/s^2, while trainings had an average PLA of 18.8 +/- 5.6 g and PRA of 1584 +/- 1145 rads/s^2. On average, each player experienced 2.0 +/- 2.2 HAE's above 55 g across a season of rugby participation.

CONCLUSION: Adolescent female rugby players are subject to a moderate number of HAE's during the season, predominantly in games. Only 3% of HAE's exceeded the 55 g threshold set by World Rugby for adult female players, which in our situation, under the new World Rugby laws would result in a single player being removed from play twice during a season of rugby participation. This study highlights the need for sex and age specific, objective data to measure head impact exposure in rugby union. Monitoring head impact magnitude and incidence is important for rugby safety and understanding the effect of concussive and non-concussive HAE in rugby union, both acutely and over the longer term.

EFFECTS OF SUPPLEMENTAL ECCENTRIC TRAINING OR CHANGE OF DIRECTION MODIFICATION TRAINING ON CHANGE OF DIRECTION PERFORMANCE AND KINEMATICS IN ADOLESCENT MALE FOOTBALL PLAYERS

NAKAMURA, H., YAMASHITA, D., NISHIUMI, D., NAKAICHI, N., HIROSE, N.

WASEDA UNIVERSITY: WASEDA DAIGAKU

INTRODUCTION: Change of direction (COD) ability is considered a critical motor ability in football, with recognized potential for improvement across various adolescent age groups. Previous studies have shown the effectiveness of eccentric training and COD modification training in enhancing COD performance among adults. However, information on the efficacy of these training methods in adolescents remains limited. This study aimed to compare the effects of different training methods on COD performance and kinematics among adolescent male football players.

METHODS: Fifty-eight junior high school male football players participated in this study and they were divided into three groups: Control group (CON group) consisted of 16 players who adhered to regular soccer training only. In addition to the regular soccer training, 21 players underwent COD modification training, which included drills at various angles and distances (COD group); another 21 players engaged in strength and plyometric training with an emphasis on the eccentric phase of movement (SP group). The seven-week intervention consisted of 12 sessions, each lasting approximately 15 minutes and held once or twice weekly. Participants underwent three trials of the Pro-Agility test and two trials of the 20 m sprint test before and after the intervention.

Total time was measured using timing gates for both the Pro-Agility and 20 m sprint tests, with the COD deficit (CODD) determined by the difference between these results. 3D kinematic data from the Pro-Agility test were obtained using a markerless motion capture system, facilitating the calculation of the center of mass (COM) velocity and kinematics for the trunk and lower limbs. The test consisted of 5 m, 10 m, and 5 m segments, each divided into acceleration (Acc) and deceleration (Dec) phases based on COM velocity, and further divided into early and late halves. The mean acceleration of the COM for each phase was computed. A two-way mixed ANOVA, incorporating both group and time as factors, was conducted, with Bonferroni-corrected pairwise comparisons applied for detailed analysis when significant interaction effects were noted.

RESULTS: Significant interactions were observed for CODD, 2nd Late Dec, 2nd Early Acc, and trunk lateral lean angle at 2nd turned foot contact. CODD was significantly improved in the COD group (p=0.027). 2nd Late Dec was significantly increased in the COD and the SP group (p=0.012 and 0.006, respectively). 2nd Early Acc was significantly decreased in the SP group (p=0.002). Trunk lateral lean angle at 2nd turned foot contact were significantly increased in the COD group (p= 0.004).

CONCLUSION: In adolescent male football players, seven weeks of strength and plyometric training improved deceleration ability in the COD task. However, it did not lead to improving COD ability. On the other hand, seven weeks of COD modification training improved deceleration ability and trunk kinematics in COD task and it led to improving COD ability.

EXERCISE INTERVENTION IN PREVENTION AND TREATMENT OF ACUTE TOXIC ACTIONS OF PLATINUM-BASED CHEMOTHERAPY IN PATIENT WITH TESTICULAR CANCER: A CASE REPORT

OLIVA, V., UKROPCOVÁ, B., UKROPEC, J., MEGO, M., CHOVANEC, M., FORIŠEK PAULOVÁ, P., SEDLIAK, M.
COMENIUS UNIVERSITY IN BRATISLAVA, FACULTY OF PHYSICAL EDUCATION AND SPORT

INTRODUCTION: Testicular cancer (TC) is the most common type of malignancy in young adult males of European ancestry and the incidence is still increasing steadily (1). Multi-disciplinary care, including orchiectomy and cisplatin combination chemotherapy (CHT), have resulted in dramatic improvement in the cure rate for TC and nowadays is considered as one of the most curable malignancies (2, 3). However, platinum-based CHT is associated with toxic actions and dysfunctions in non-targeted tissues (4). Exercise seems to be promising as adjuvant therapy in reducing some of the toxic actions and dysfunctions in patients undergoing platinum-based CHT (2, 4, 5). This case report explored the effects of exercise intervention on body composition, muscle strength, power, muscle endurance and cardiorespiratory fitness (CRF) in TC patient during the treatment.

METHODS: Patient (age 50 y., height 172 cm, body weight 85,2 kg, BMI 28,8 kg/m2) diagnosed with seminoma underwent orchiectomy and 4 cycles of etoposide, cisplatin CHT treatment. Supervised and home-based exercise intervention was implemented during the 11-week treatment period where strength and aerobic training was performed. Electrical bioimpedance (BF511, OMRON, Japan) was used to assess fat mass, visceral fat and lean mass. Maximum muscle strength was assessed using the hand grip dynamometer (CAMRY EH101, China). Linear position transducer (FitroDyne Premium, FiTRONiC s.r.o., Slovakia) was used to assess muscle power during the counter-movement jump. Compound exercises were used to assess muscle endurance of upper and lower body. CRF was assessed by modified 3-minutes Step test ("YMCA version").

RESULTS: After implementing exercise intervention during 12-week platinum-based CHT treatment period, we observed reduction in fat mass (-2,2%), visceral fat (-2,0) and increase in lean mass (+1,1%). Despite observing slight reduction in maximum muscle strength, there were slight increase in muscle power production (+0,3%) and large increases in muscle endurance of lower and upper body (+20%, +5,7%, respectively). There was also an improvement observed in CRF (+14,3%).

CONCLUSION: Exercise intervention during anti-cancer treatment may have the potential to ameliorate and/or reverse some acute toxic effects in TC patients. Rationale exists for the promotion of exercise oncology research in this setting, in order to provide exercise recommendations for patients during the treatment.

The contribution was created with the support of APVV-19-0411.

EFFECTIVENESS OF A PREOPERATIVE HOME-BASED EXERCISE PROGRAM ON QUALITY OF LIFE AND PHYSICAL PERFORMANCE AFTER LUNG CANCER RESECTION: A SINGLE-BLINDED MULTICENTER RANDOMIZED CONTROLLED TRIAL

MACHADO, P., PIMENTA, S., GARCIA, A.L., NOGUEIRA, T., SILVA, S., DOS SANTOS, C.L., MARTINS, M.V., CANHA, A., OLIVEIROS, B., MARTINS, R.A., CRUZ, J.

INSTITUTO POLITÉCNICO DE LEIRIA

INTRODUCTION: Exercise prehabilitation has shown to improve clinical outcomes after lung cancer surgery. However, its efficacy in preventing deterioration in postoperative quality of life (QoL) has not been determined. Moreover, although patients awaiting major cancer surgery express a preference to exercise in their home-based environment, most prehabilitation trials in lung cancer surgery have focused on hospital-based interventions. The main purpose of this study was to investigate whether a preoperative home-based exercise program (PHEP) prevents the deterioration in QoL after lung cancer surgery. Secondarily, it aimed to determine the effects of the PHEP on physical performance.

METHODS: A parallel, assessor-blinded, randomized controlled trial was conducted at 4 hospitals in Portugal. Patients awaiting lung cancer resection (clinical stage I-IIIA), were randomly allocated to either a non-exercise control group (n=21) or to a PHEP group (n=20). The PHEP consisted of moderate-intensity aerobic plus resistance training, with weekly telephone supervision. Primary endpoint was QoL measured with the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire C-30. Secondary endpoints were exercise capacity (incremental shuttle-walk test) and muscle strength (maximal handgrip strength and 5 times sit-to-stand). Outcomes were measured at baseline (i.e., before randomization), 1-5 days pre-surgery, and 1-month post-surgery. A repeated measures analysis of variance (ANOVA) was employed to compare groups over time based on the intention-to-treat principle. The proportion of patients who had clinically relevant deterioration on QoL was analyzed based on the minimal importance difference.

RESULTS: A significant group X time interaction was found for global QoL (p=0.004). Significantly and clinically relevant differences between groups were found on global QoL at pre-surgery (mean difference [MD], 13.5 points; 95% confidence interval [CI], 2.4–24.6; p=0.019) and post-surgery (MD, 12.4 points; 95% CI, 1.3–23.4; p= 0.029), favoring the PHEP group. After surgery, the proportion of patients who had a clinically relevant deterioration on QoL was significantly lower in the PHEP group compared with the CG in the following domains: physical function (PHEP: 20% vs CG: 66.7%; p=0.004), role function (PHEP: 10% vs CG: 52.4%; p=0.006), social function (PHEP: 15% vs CG: 47.3%; p=0.043), pain (PHEP: 25% vs CG: 61.9%; p=0.028) and appetite loss (PHEP: 5% vs CG: 38.1%; p=0.020). In addition, between-group differences were found in preoperative five-times sit-to-stand (median difference, –1.8 s; 95% CI, –0.1 to –3.7 s; p=0.041) and postoperative exercise capacity (MD, 147.4 m; 95% CI, 17.3–264.2 m; p=0.027), favoring the PHEP group. No between-group differences were found on handgrip strength.

CONCLUSION: This study found that a PHEP prevents deterioration in QoL and exercise capacity after lung cancer surgery. Further research is needed to determine its efficacy on surgical outcomes.

MULTIMODAL HOME-BASED PREHABILITATION FOR COLORECTAL CANCER PATIENTS WITH REDUCED SURGERY WAIT TIMES: A PILOT SERVICE

DE KLERK, T., CAMPBELL, A.1, BRUN-LACEY, E.2, COLLINS, D.2, PITKETHLY, A.1, LOUDON, D.3, MAXWELL, D.3, KALIARNTAS, K.1

[1]EDINBURGH NAPIER UNIVERSITY, SCHOOL OF APPLIED SCIENCES., [2]NHS WESTERN GENERAL HOSPITAL EDINBURGH., [3]PAL TECHNOLOGIES LTD.

INTRODUCTION: Multimodal prehabilitation is the systematic process of improving patients physical, emotional, and nutritional status between diagnosis and surgery [1]. Patients with better health status before bowel surgery, show improved response to treatment, experience less complications, have shorter hospital stays and improved quality of life [2]. Given the short surgery wait times for colorectal cancer patients, current prehabilitation guidelines are insufficient. This pilot service evaluated the tolerability and feasibility of multimodal high intensity interval training (HITT) with higher frequency (>5 days/week) to optimise patients within reduced surgery wait times (< 4 weeks).

METHODS: Ten patients received personalised home-based exercise, breathing and pelvic floor exercise, nutritional advice and emotional support using motivational interviewing. Primary outcome: functional walking capacity (six-minute walk test [6MWT]). Secondary outcomes: muscular strength/endurance (sit to stand test [STS]), self-efficacy for exercise, anxiety/depression (Hospital Anxiety and Depression Scale [HADS]), nutritional status (Malnutrition Universal Screening Tool ([MUST]), quality of life (EQ-5D-5L), adherence, sedentary behaviour change, affect regulation and patient satisfaction. Distribution dependant, appropriate descriptive (mean±standard deviation; median/range) and inferential (paired T-tests; Wilcoxon) statistics were used and statistical significance set at $p < .05$.

RESULTS: Prehabilitation (median:20, range:6-35 days), improved all functional outcomes. Affect regulation improved significantly. 6MWT distance increased by 16.9m±96m (p=.6), STS increased by 31.1% (Mean Difference (MD) 3.5±6.2, p=.1). EQ-5D-5L Index score improved by 5.6% (MD=.04±.09, p=.1) and self-reported health status by 26.5% (MD=16±24.6, p=.07), HADS Fear by 13.6% (MD=.9±4.7, p= .5) and HADS Depression by 10.5% (MD=.4±3.9, p=.7). Patients reported 16.9% more confidence to partake in exercise (MD=10.9±20.9, p=.1). Body mass index (BMI) improved significantly (MD=.6±.6, p=.03). Resting blood pressure improved by 8.7% systolic/3.7% diastolic pressure. Patients managed mean physical exercise of 79±66 mins/session, and cumulatively 119.9±39.3 activity mins/day. Significant affective improvements in activation (arousal) (MD=.5±0.9, p<.00) and affective valence (feeling) (MD=.6±1, p<.00) were observed be-

fore/after exercise when intensity was self-selected. Adherence was excellent, patient satisfaction increased, and no adverse events occurred.

CONCLUSION: Multimodal home-based HITT prehabilitation with high frequency is feasible and tolerable within reduced surgery wait times. Optimal results may require >3 weeks of physical exercise and early referral is vital. These findings have important implications for informing current clinical practice.

VARIETY IS THE SPICE OF RESISTANCE TRAINING? – COMPARISON OF UNDULATING AND TRADITIONAL HYPERTROPHY TRAINING IN CANCER SURVIVORS: A RANDOMIZED CONTROLLED TRIAL

BAUER, N., SCHNEIDER, J., SCHLÜTER, K., WISKEMANN, J.

NATIONAL CENTER FOR TUMOR DISEASES HEIDELBERG

INTRODUCTION: Optimizing resistance training through periodization is essential for improving strength performance. In this context, undulating resistance training is considered an effective method for structuring resistance training in healthy recreational and competitive athletes (Harries, Lubans, & Callister, 2015). However, to date there are no studies in the field of exercise oncology that have compared volume-matched undulating strength training with traditional hypertrophy training in cancer survivors.

METHODS: 37 breast and 30 prostate cancer survivors were randomly assigned to either undulating (UND, n = 34, age 60±9 years) or standard hypertrophy training (STD, n = 33, age 58±11 years). Both groups performed two machine-based resistance trainings per week with matched training volume over an intervention period of 12 weeks. As primary outcome, strength performance of the knee extensors was assessed by maximal isokinetic peak torque (MIPT) and one-repetition maximum (1-RM) test. In addition, MIPT and maximal voluntary isometric contraction (MVIC) for knee, hip and elbow extensors/flexors as well as 1-RM for leg curl, rowing, lat pull-down, leg press and shoulder press were examined.

RESULTS: 27 (UND) (13 women) and 26 (STD) (16 women) patients were included in the analysis. Concerning the primary outcome, MIPT ($p<.05$) and 1-RM ($p<.001$) show that both groups significantly improved knee extensor strength. There was no significant group difference. Comparably, nearly all secondary endpoint parameters showed significant strength gains over time without group differences ($p>.05$).

CONCLUSION: Undulating and standard hypertrophy resistance training both resulted in comparable effects on strength performance in cancer survivors. Both training regimens showed no differences with regard to safety and feasibility in cancer survivors.

DOES TIMING OF ORAL CONTRACEPTIVE PILL INTAKE AFFECT EXERCISE PERFORMANCE? A RANDOMIZED CROSSOVER CONTROLLED STUDY

SMITH BISGAARD, M., HANSEN, M.

AARHUS UNIVERSITY

INTRODUCTION: Combined oral contraceptive pills (OCP) containing synthetic estradiol and one type of progestin are used by 27 to 41% of female athletes in various European countries [1-3]. Previous research indicates a potential slightly reduced exercise performance in OCP users compared to non-OCP users [4]. However, the acute effect of OCP intake on athletic performance has not been studied.

During OCP use, the endogenous levels of sex hormones are downregulated to fairly constant low levels. However, serum concentrations of the exogenous sex hormones from the OCP peak between one and two hours after pill intake [5, 6], but already after eight hours, the concentrations of exogenous hormones have declined to low levels. Whether these fluctuations affect exercise performance remains undetermined.

We aimed to investigate a potential acute effect of OCP intake on strength, power, and endurance performance in trained females.

METHODS: Twenty-two trained young females using monophasic 2nd generation OCPs were tested in a randomized cross-over controlled study. Participants completed a physical performance test protocol twice during the active OCP period. In randomized order, the participants completed the tests one hour after intake of the OCP and 24 hours after

intake of the OCP respectively. The physical tests included a balance stand test, a muscular endurance push-up test, an agility test, and measurements of isometric handgrip strength, countermovement jump height, flexibility and a maximal oxygen uptake bike test. In addition, a questionnaire about psychological wellbeing was completed before testing. Time of the day, energy intake and exercise 24 hours preceding the tests was standardized and participants were familiarized with the tests beforehand. Serum and saliva hormone analysis ensured OCP compliance and exact levels of exogenous hormones at the time of testing.

RESULTS: No significant difference in exercise performance parameters was observed between the test days; OCP intake one hour before testing versus 24 hours before testing.

CONCLUSION: Collectively, timing of OCP intake in young, trained females did not significantly affect exercise performance parameters. This study indicates, that female athletes using OCPs and pursuing to optimize their physical performance, can omit concerns on when to take their OCP.

ALTERATIONS IN PERCEIVED TRAIT FATIGUE DURING THE MENSTRUAL CYCLE DID NOT AFFECT PERFORMANCE FATIGUE DURING SUBMAXIMAL KNEE EXTENSION EXERCISE TO EXHAUSTION IN EUMENORRHEIC FEMALES

BIELITZKI, R., BEHRENS, M., BEHRENDT, T., ROß, L.M., DOROW, N., SCHEGA, L.

OTTO VON GUERICKE UNIVERSITY

INTRODUCTION: The influence of the menstrual cycle (MC) on female athletic performance and its underlying mechanisms have been largely investigated with conflicting results. A recent study by Ansdell et al. (J Appl Physiol. 2019;126:1701–12) revealed that time-to-exhaustion during a submaximal task was higher on Day 21 [mid-luteal] compared to Day 2 [early follicular] without differences in the strength, voluntary activation and decline in contractile function of the knee extensors. However, endurance performance (i.e., time-to-exhaustion) is not only influenced by neuromuscular but also perceptual factors. Therefore, the present study aimed to investigate time-to-exhaustion and the perceptual responses during the same exercise used by Ansdell et al. across the MC. Furthermore, the influence of trait fatigue and trait mood (assessed over the last 7 days) was examined.

METHODS: Fifteen eumenorrheic females (24.1±3.3yrs, 63.4±4.8kg, 166.2±5.0cm) participated in a pseudo-randomized, counterbalanced cross-over study. Participants completed a familiarization session and three experimental trials on different days during the MC (Day 2 [early follicular], 14 [late follicular], and 21 [midluteal]). The fatiguing exercise consisted of isometric knee extensions at 60% of maximal voluntary isometric contraction (MVIC) torque until exhaustion. The protocol consisted of sets with 12 repetitions (3s contraction/ 2s rest). On each 12th repetition, a MVIC was performed to quantify the performance reduction (i.e., motor performance fatigue) At the end of each set perceived motor fatigue, affective valence, arousal, pain and effort percep-tion were queried. Furthermore, motivation to perform the fatiguing task (Dundee Stress State Questionnaire), trait fatigue (Modified Fatigue Impact Scale), and trait mood (Profile of Mood States) were recorded before each experimental session.

RESULTS: There were no differences in time-to-exhaustion, the MVIC decline and the perceptual responses during exercise across the 3 trials. However, motivation to perform the fatiguing task was lower on Day 2 compared to Day 21 ($p=0.030$. $d=0.45$) and trait mood was worse on Day 2 compared to Day 14 ($p=0.007$, $d=0.85$). Of note, a high but non-significant effect was found for trait fatigue ($p=0.081$, $\eta p2=0.18$) with higher values on Day 2 compared with Day 14 ($p=0.079$, $d=0.56$).

CONCLUSION: The MC had an effect on motivation to perform the fatiguing task and trait mood as well as trait fatigue with the worst values on Day 2. However, time-to-exhaustion, motor performance fatigue, and the perceptual responses during exercise were not affected. These results indicate that MC-related alterations in motivation, trait mood and trait fatigue do not inevitably affect motor task performance and/or motor performance fatigue.

INFLUENCE OF MENSTRUAL CYCLE PHASE OR HORMONAL CONTRACEPTIVE PHASE ON PEAK FAT OXIDATION

LÖFBERG, I., KARPPINEN, J.1,2, LAATIKAINEN-RAUSSI, V.1, IHALAINEN, J.1,3, LEHTI, M.1, KYRÖLÄINEN, H.1, HACKNEY, A.4, MIKKONEN, R.1

1UNIVERSITY OF JYVÄSKYLÄ; 2UNIVERSITY OF HELSINKI; 3RESEARCH INSTITUTE FOR OLYMPIC SPORT ; 4UNIVERSITY OF NORTH CAROLINA

INTRODUCTION: Estradiol (E2) and progesterone (P4) are suggested to influence substrate use during exercise [1]. Previous literature indicates higher fat oxidation during submaximal continuous exercise in the luteal phase (LP) of the menstrual cycle (MC) compared to the follicular phase (FP) [2]. Evidence regarding fat oxidation during exercise in women using hormonal contraceptives (HC) is sparse but indicates no clear differences between active (AP) and inactive hormonal

phases (IP) [3]. This study aimed to examine differences in peak fat oxidation (PFO) between hormonally confirmed MC phases in naturally menstruating women (NoOC) and HC phases in women using combined monophasic oral contraceptives (COC).

METHODS: Healthy untrained women (Tier 1) [4] aged 18–35 years with a body mass index between 19.5 and 35 kg/m² were recruited to this study and divided into NoOC- (n=35) and COC-group (n=19). Participants were measured after overnight fast in the FP/LP or the AP/IP of the MC or HC cycle, respectively. E2 and P4 were measured using immunoassays and body composition via bioimpedance. Fat oxidation was measured using indirect calorimetry during a graded treadmill PFO test consisting of 4-min stages. The initial speed and gradient were 4.5 km/h and 1.2°, respectively. The speed increased by 1 km/h in the first two stages and the gradient increased by 1.2° from the third stage onwards until participants reached a respiratory exchange ratio of 0.95 [5]. Fat oxidation was calculated for the last minute of each stage and the highest rate achieved was selected as the PFO. MC or HC phases were compared using paired t-test. Associations between E2/P4 and PFO were analyzed with multiple linear regression using fat free mass (FFM) as a covariate.

RESULTS: All participants in the NoOC-group had P4 level ≥16 mmol/l in the LP and higher E2 and P4 concentrations in the LP than in the FP ($p<0.001$). E2 and P4 did not change from AP to IP in the COC-group. In the NoOC-group, PFO was 0.40 g/min (SD 0.09) in the FP and 0.43 g/min (SD 0.12) in the LP (mean difference 0.03, 95% CI -0.02–0.07, $p=0.253$). In the COC-group, PFO was 0.44 g/min (SD 0.11) in the AP and 0.48 g/min (SD 0.12) in the IP (mean difference 0.04, 95% CI -0.01–0.09, $p=0.099$). E2/P4 were not significantly ($p>0.05$) associated with PFO in any of the MC/HC phases.

CONCLUSION: E2 and P4 fluctuations during the MC cycle or the use of COC do not notably affect PFO. This discrepancy with previous work may result from the use of different testing protocols, as most studies reporting higher fat oxidation during the LP have used prolonged single-stage exercise, which is known to be crucial for maximal lipolysis [6].

THE INFLUENCE OF MENSTRUAL CYCLE PHASE ON DURABILITY

DOCTER, H., TAYLOR, M., MÜLLER, A., OSBORNE, J.O., SANDBAKK, Ø., DE KONING, J.J., NOORDHOF, D.A.

NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: In addition to maximal oxygen uptake (VO2max), fractional utilization of VO2max, and efficiency1, durability has been regarded as an important determinant of endurance performance2. Durability may be reflected by the change in any of the three other determinants over time,3. In women, a drop in repeated sprint performance following a simulated cycling race is exacerbated in the mid luteal phase4. However, it is unclear if menstrual cycle phase influences the ability to maintain efficiency. This study aimed to evaluate the ability to maintain efficiency after completing a high-intensity training session, and whether this ability is influence by the menstrual cycle.

METHODS: Twenty-four female endurance-trained females performed a high intensity training session (5x5min at 80% of velocity or power output at VO2max, 2min rest) on a treadmill or cycle ergometer in the early follicular (EF), ovulatory (O), and mid luteal (ML) phase of one menstrual cycle. Menstrual cycle phases were determined using the determined using calendar-based counting, urinary ovulation testing, and analysis of ovarian hormones. Metabolic power per kg body mass was calculated using gas exchange data during submaximal exercise (60% of velocity or power output at VO2max) before and after each training session and used as a measure of efficiency.

RESULTS: A multilevel linear model revealed a higher metabolic power after the training session ($p=0.041$, $r=0.24$) compared to before. A second model revealed that menstrual cycle phase did not significantly affect the change in metabolic power (EF vs. O: $p=0.388$, $r=0.16$, O vs. ML: $p=0.306$, $r=0.19$), although a medium effect size was found between the EF and ML phase ($p=0.058$, $r=0.35$; mean±SE running EF: -0.51±6.31W/kg, O: 6.04±14.9W/kg, ML: 13.96±6.82W/kg; cycling EF: -2.86±15.0W/kg, O: 3.69±6.65W/kg, ML: 11.6±14.9W/kg). The population of interest makes the study vulnerable for small sample sizes, which may have led to a low statistical power.

CONCLUSION: Efficiency is reduced following a high-intensity training session. There is some indication that the ability to maintain efficiency may be more compromised in the ML compared to the EF phase. However, due to the low statistical power no conclusions on the effect of menstrual cycle phase on durability can be drawn.

PROGESTERONE AND ESTRADIOL LEVELS DO NOT CORRELATE WITH SPRINT PERFORMANCE IN YOUNG PLAYERS WITHOUT CONTRACEPTION

IMBERT, S., DAUSSIN, F.N.
UNIVERSITÉ DE LILLE

INTRODUCTION: Rugby is an intermittent team sport in which acceleration and maximal speed are key parameters involved in performance. In womens physiology, the question of whether the menstrual cycle can influence performance is increasingly present in the scientific literature. The aim is to find out whether athletes hormonal levels can influence their speed performance.

METHODS: Nineteen young female rugby players (mean age: 15.9 ± 0.7 years, mean body mass: 67.4 ± 13 kg, mean height: 165 ± 7.9 cm) playing at the highest youth level were involved in this study. Players do not take contraception. Saliva samples were taken once a week on waking to determine their progesterone (pg/ml) and estradiol levels (pg/ml) during sixteen weeks. On the same day, the players performed two 40m sprints. The sprint performances were recorded and analyzed using a Global Positioning System (GPexe GPS Micro-technology) to determine the in-situ acceleration-speed profile. The analysis allowed us to determine the maximal theoretical acceleration (A0 in m/s2) and the maximal theoretical speed (V0 in km/h). Correlation between force-velocity parameters and progesterone and estradiol levels were tested. The players were asked to fill out a questionnaire about their feelings during the different hormonal cycles.

RESULTS: No correlation was found between progesterone (52.7±41) and estradiol (4.5±2.5) levels with maximal speed (25±1.6) respectively p=0.4 and p=0.18, V0 (26.4±1.7), p=0.34 and p=0.57, and A0 (5.7±0.6), p=0.29 and p=0.32. The analysis of the questionnaire on how the players felt about their menstrual cycle. Revealed that 71% of the players felt that, at least at times, it hurt their performance and only 9% of the players thought that it had a positive impact.

CONCLUSION: While hormonal variations occur during each cycle, no correlation was observed with in situ force-velocity profile parameters. These results contrast with the players feelings. Our data suggest that in the follow-up of young female players, hormonal monitoring is not a priority, especially when considering neuromuscular performance.

OP-MH21 Exercise and vascular function

THE MECHANICAL MECHANISM OF EXERCISE IMPROVING HYPERLIPIDEMIA-INDUCED ENDOTHELIAL INJURY: SHEAR STRESS ACTIVATES PIEZO1 TO PROMOTE MITOCHONDRIAL FUSION

LIU, X.
XI'AN JIAOTONG UNIVERSITY

INTRODUCTION: Physical exercise improves hyperlipidemia-induced endothelial injury by reducing circulatory lipid levels and enhancing mitochondrial function in vascular endothelial cells. However, the exact mechanism underlying its protective effects remains uncertain, despite recent research indicating that blood flow shear stress is a key mechanism through which exercise enhances endothelial function. It is still unclear whether blood flow shear stress contributes to the exercise-induced improvement of endothelial injury caused by hyperlipidemia, and the specific mitochondrial molecular mechanism remains to be elucidated. Piezo1, as a newly discovered mechanosensitive ion channel protein, plays a crucial role in response to mechanical stress.

METHODS: In this study, we utilized long-term and short-term hyperlipidemia models to elucidate the role of exercise in improving vascular damage caused by hyperlipidemia and whether fluid shear stress is involved. Furthermore, pharmacological interventions (PIEZO1 agonists and inhibitors) and PIEZO1 knockout mice were employed to validate PIEZO1 as a key molecule in exercise-induced improvement of hyperlipidemia-associated vascular damage. Finally, utilizing cellular and molecular biology techniques, we elucidated the molecular mechanism by which fluid shear stress promotes mitochondrial fusion through PIEZO1, thereby improving endothelial function.

RESULTS: This study demonstrated that exercise can increase blood flow shear stress and ameliorate endothelial injury in both long-term and acute hyperlipidemia models. Additionally, intravenous injection of the Piezo1 agonist Yoda1 into the tail vein has a similar effect to exercise in mitigating endothelial injury. Conversely, the beneficial effects of exercise in improving endothelial injury diminish in endothelial-specific Piezo1 knockout mice and following intravenous injection of the Piezo1 inhibitor GsTMx-4, indicating that Piezo1 is a crucial molecule for exercise-induced improvement of endothelial injury. Furthermore, in vitro experiments revealed that isolated mitochondria can directly respond to fluid shear stress and Yoda1. Blood flow shear stress can enhance endothelial cell mitochondrial fusion and function by activating the Piezo1-Mfn2-eNOS signaling axis.

CONCLUSION: These findings unveil a novel mechanism by which exercise promotes endothelial cell function by increasing blood flow shear stress to activate the Piezo1-Mfn2-eNOS signaling axis, and suggest that Piezo1 may present a new target for preventing and treating hyperlipidemia-induced endothelial injury.

MICROVASCULAR FUNCTION IMPAIRMENTS AFTER STEPS REDUCTION IN YOUNG SUBJECTS

GIUSTI, L., MARCIANO, A., NERI, M., BOTTINELLI, R., PORCELLI, S.

UNIVERSITÀ DI PAVIA

INTRODUCTION: Inactivity is an important and independent risk factor for all-cause mortality, and there is increasing evidence of the importance of minimizing sedentary behavior to reduce the risk of cardiovascular diseases (1). Endothelial dysfunction plays an important role in the pathogeneses of cardiovascular diseases, and impaired endothelium dependent dilation is directly linked with cardiovascular morbidity and mortality (2). Bedrest, which is a classical model utilized to study the physiological effects of severe inactivity, showed a negative impact on endothelial function (3,4). The effects of steps reduction, a milder form of inactivity, on microvascular responsiveness are currently unclear. In the present study, we investigate the effects of 14 days of steps reduction on microvascular function, evaluating acute post-occlusive reactive hyperemia by near-infrared spectroscopy (NIRS).

METHODS: Eighteen young subjects (12 males and 6 females; age: 22±3y, weight: 69.1±11.9kg, height: 172±7cm) were assessed before (PRE) and after 14 days of steps reduction (SR). Their physical activity was monitored through an accelerometer worn on the waist. Microvascular function was estimated by monitoring changes of tissue saturation index (TSI) during a prolonged ischemia followed by a reperfusion phase. The rate of muscle deoxygenation during the first minute of occlusion (Slope1) was used as proxy of resting muscle oxygen uptake. Time of ischemia (t-isch) and the lowest TSI value reached during occlusion (TSImin) were calculated to estimate the ischemic vasodilatory stimulus. The rate of muscle reperfusion during 10s (Slope2-10s) post-ischemia and the magnitude of reperfusion (TSIpeak) were calculated.

RESULTS: Steps count was effectively reduced by 82% from PRE to SR. Slope1 was not different between PRE (-0.11±0.07%*s-1) and SR (-0.12±0.10%*s-1; p=0.436). TSImin was lower after SR compared to PRE (46.2±7.1% vs 43.2±8.5%, respectively; p<0.05). Slope2-10s was similar between PRE (1.16±0.59%*s-1) and SR (1.12±0.38%*s-1; p=0.573) but it resulted significantly reduced after SR (-13%) when normalized for the ischemic vasodilatory stimulus.

CONCLUSION: After 14 days of steps reduction, resting muscle oxygen uptake did not change whereas endothelial function was impaired. Thus, a mild reduction of daily activity induced alterations at microvascular level, which are probably due to lower nitric oxide (NO) bioavailability and partial structural vascular modifications.

CAN SET CONFIGURATION MODULATE THE ARTERIAL STIFFNESS AND POST-EXERCISE HYPOTENSION RESPONSE IN POSTMENOPAUSAL WOMEN?

RÚA ALONSO, M., REVUELTA-LERA, B., NINE, I., RIAL-VÁZQUEZ, J., FARIÑAS, J., RIVERA-MEJÍA, S.L., OVIES-GUTIERREZ, F., IGLESIAS-SOLER, E.

UNIVERSITY OF A CORUÑA - Q6550005J

INTRODUCTION: Menopause is a critical phase in women's health, increasing the risks of hypertension and vascular dysfunction (1). Resistance exercise (RE) can promote a post-exercise hypotensive response in postmenopausal women (2). Set configuration can modulate the acute cardiovascular response to RE (3,4). However, menopause may influence the acute effects to exercise (2). Therefore, the aim of this study was to explore arterial stiffness and blood pressure response in postmenopausal women after RE protocols with different set configurations.

METHODS: 50 postmenopausal women with a physically active lifestyle (37 normotensive/13 hypertensive) participated in this study funded by the Spanish Ministry of Science and Innovation (PID2021-124277OB). After a medical screening and familiarisation with the RE protocol composed by four exercises, each woman completed one control (CON) and three experimental sessions equated by intensity (12RM load), volume (144 reps) and total resting time (18min), but differing in set configuration: 9 sets of 4 reps with 45s rest (9S); 6 sets of 6 reps with 72s rest (6S); and 4 sets of 9 reps with 120s rest (4S).

Arterial stiffness, measured by pulse wave velocity (PWV), was assessed before, immediately after, and 60 min after session. Blood pressure, including systolic (sBP), diastolic (dBP), and mean arterial pressure (MAP), as well as low frequency of SBP oscillations (LFsBP), were evaluated before and after each session at intervals of 5-15, 15-25, 30-40, and 40-50min.

RESULTS: No differences between normo- and hypertensive participants were observed.

ANOVA analysis detected a main effect of time, session, and time×session interaction ($p \leq 0.002$) for PWV. Immediately after session, all RE protocols caused higher values than CON ($p \leq 0.006$). Increases compared to baseline were observed only after 6S and 9S ($p \leq 0.039$), with no significant differences between the experimental sessions. After 60min from the end of the session, all RE protocols showed a reduction in PWV compared to immediately post-exercise records ($p \leq 0.005$), without differences between experimental sessions and CON ($p \geq 0.075$). Only a main effect of time was observed for sBP, MAP and LFsBP ($p \leq 0.021$).

CONCLUSION: Set configuration may modulate the arterial stiffness response after exercise, despite the absence of a post-exercise hypotension response in physically active postmenopausal women. Long set configurations increase arterial stiffness without providing the hypotensive benefit. Thus, in order to reduce the cardiovascular risk while still reaping the benefits of RE, short set configurations (i.e., an intensity of effort of 33%, 4 out of 12) should be recommended for postmenopausal women, similar to healthy young people (3,4).

COMPARATIVE EFFECTS OF DIFFERENT TYPES OF EXERCISE ON ENDOTHELIAL FUNCTION, ARTERIAL STIFFNESS, AND EXECUTIVE FUNCTION IN SEDENTARY YOUNG INDIVIDUALS: A RANDOMIZED CONTROLLED TRIAL

HUANG, J., YAN, X.
GUANGZHOU SPORT UNIVERSITY

INTRODUCTION: The present study aimed to determine whether high-intensity interval training (HIIT), moderate-intensity continuous training (MICT), and resistance exercise (RE) have different effects on endothelial function, arterial stiffness, and executive function (EF) in sedentary young individuals and explore the underlying mechanisms.

METHODS: Sixty-three sedentary participants were randomly divided into the HIIT, MICT, RE, and control groups. Macrovascular and microvascular endothelial function were assessed by measuring brachial artery flow-mediated dilation (FMD) and fingertip reactive hyperemia index (RHI), respectively. Arterial stiffness was evaluated by carotid-femoral pulse wave velocity (cfPWV), brachial-ankle pulse wave velocity (baPWV), ankle-brachial index (ABI), and augmentation index (AIx). EF performance was evaluated through Stroop and N-back tasks. The functional near-infrared spectroscopy (fNIRS) was employed to measure the cortical activation and real-time oxyhemoglobin concentration (Oxy-Hb) changes in different cerebral regions.

RESULTS: Compared to the baseline, mean shear rate, FMD, and RHI significantly increased and cfPWV significantly decreased in all three intervention groups but not the control group after 8 weeks of intervention. However, significant changes in FMD and peak diameter were seen in the HIIT group and the MICT group rather than the RE group, compared to the control group. In addition, a significant difference in the change of RHI was only observed between the control group and the HIIT group.

Compared to the baseline, the reaction time in the Incongruent Stroop task and the 3-back task significantly decreased after 8 weeks of HIIT and MICT. However, reduced reaction time in the Stroop interference task and the 2-back task were only observed in the HIIT group. During the Stroop task, the Oxy-Hb in the frontopolar area (FPA) significantly increased after 8 weeks of HIIT and MICT. Furthermore, significant increase in Oxy-Hb in the orbitofrontal area were only observed in the RE group, and significant increase in Oxy-Hb under the left of dorsolateral prefrontal cortex (L-DLPFC) and the right of dorsolateral prefrontal cortex (R-DLPFC) were only observed in HIIT. During the N-back tasks, the Oxy-Hb in the FPA region significantly increased after 8 weeks of HIIT and MICT. Furthermore, significant increases in Oxy-Hb under the L-DLPFC region were only observed in HIIT.

CONCLUSION: Eight weeks of HIIT, MICT, and RE effectively improved macrovascular and microvascular endothelial function and arterial stiffness in sedentary young individuals. However, HIIT and MICT rather than RE efficiently activated certain brain regions such as FPA and DLPFC and improved EF. Among these three exercise types, HIIT seemed to be the most effective to improve vascular and cognitive function in this population. Importantly, enhanced vascular function by exercise training is pivotal to the improvement in cognitive function.

A PHYSICAL ACTIVITY INTERVENTION WALKING-BASED CAN REDUCE PRO-OXIDANT ACTIVITY IN POLYATHEROMATIC PATIENTS

PIALOUX, V., MURA, M., RIVOIRE, E., KHENNICHE, L., THOMAS, A., MILLON, A.
UNIVERSITY CLAUDE BERNARD LYON 1

INTRODUCTION: Atherosclerosis remains a major contributor to the global burden of deaths. Atherosclerotic plaques can be located in any large artery bifurcation, as the carotid or the lower limbs (i.e. Peripheral artery disease [PAD]). As the plaque becomes unstable, it can promote thromboembolism leading into a stroke or a limp, dependent of the plaque location. A large cohort study of 3 000 participants, demonstrated that subjects with higher physical activity rates had lower odds of PAD and carotid atherosclerosis. Inflammation and oxidative stress and two major pathophysiological mechanisms involved in the development and deterioration of carotid and lower limb atherosclerosis.

The Physical Activity and Carotid Atherosclerotic Plaque haemorrhage (PACAPh) study is a 6-month interventional study. This abstract focuses on the results of circulating inflammation and oxidative stress of the PACAPh study comparing PAD non-PAD patients of the cohort.

METHODS: A total of 52 carotid atherosclerotic patients were included. At inclusion, sedentary (n=26) and non-sedentary (n=26; >8 and ≤8h/day sitting, Sedentary behaviour questionnaire); PAD (n=30) and non-PAD patients (n=22; ankle brachial index ≤ and > 0.90). Cytokines have been measured by multiplex and pro/antioxidant markers by colorimetric assay and enzymology. Wilcoxon rank-sum test was used to compare groups. Then the whole population was randomised 1:1 either in the physical activity or in the control group. In the physical activity group, the effect of the intervention on biological markers was tested in PAD and non-PAD patients. The interaction effect intervention*PAD was tested with a linear regression.

RESULTS: At inclusion, the most sedentary patients had increased blood concentrations of the pro-inflammatory cytokines CCL27, CCL11, IL1b, and MIF ($p<0.05$) in comparison with less sedentary patients. At inclusion, PAD patients had increased rates of pro-oxidant enzyme MPO ($p<0.05$) compared with patients with only carotid atherosclerosis. Moreover, the physi-

cal activity intervention decreased the concentration of MPO in patients with PAD, while it stayed stable in patients with only carotid atherosclerosis (interaction $p<0.05$).

CONCLUSION: These results suggest that the sedentary behaviour is associated with the level of circulating inflammatory markers in carotid atherosclerotic patients. It also appears that PAD increases the MPO pro-oxidant activity resulting mainly from circulating immune cells, in carotid atherosclerotic patients. More importantly, this MPO activity is reduced by our intervention specifically in PAD patients of our cohort. As our intervention is solely based on walking, it can be easily implemented in the everyday life of patients. In this context, reduce sedentary behaviour by practicing moderate intensity physical activity might be beneficial for these patients.

OP-AP09 The coach: Insights and Perspectives

EXPERT CONSENSUS ON CHARACTERISTICS IMPORTANT OR ESSENTIAL FOR ACHIEVING INTERNATIONAL PODIUM SUCCESS AS AN ELITE ENDURANCE RUNNER: A DELPHI SURVEY

ELVISH, T., KREMER, P., TROWELL, D., MILLET, E.L., TURNER, K.J., BONACCI, J., PICKERING, C., SAUNDERS, N.

DEAKIN UNIVERSITY

INTRODUCTION: Current literature identifies biological [1], psychological [2] and social characteristics [2,3] possessed by elite endurance runners. However, there is a lack of consensus on which characteristics are important for achieving podium success as an elite endurance runner. Improved understanding of the biopsychosocial profile of elite endurance-based runners can guide ongoing athlete development and allocation of resources when targeting international podium success. The aim of this study is to understand characteristics experts believe are important or essential for achieving international podium success as an elite endurance runner.

METHODS: Fourteen middle distance running (MDR) and 10 long distance running (LDR) experts participated in Round 1 and 12 MDR and eight LDR experts participated in Round 2 of a Delphi survey. Experts included coaches and practitioners who work with elite Australian able-bodied endurance-based runners. Experts were asked to rate, using a Likert scale (range:0= completely irrelevant to 5= essential), how important they believed each characteristic was for achieving international podium success in MDR and LDR. The list of characteristics presented was based on the findings of a systematic review and expert interviews, outcomes of a larger project. Characteristics endorsed as 'essential' or 'important' by >80% but <60% of experts in Round 1 were taken to Round 2. Characteristics were classified as important if ≤80% of experts endorsed the characteristic as 'essential' or 'important' [4]. Consensus was not sought beyond two rounds.

RESULTS: Of the 188 biopsychosocial characteristics presented 154 were endorsed or rejected in Round 1, hence 34 characteristics were included in Round 2. After Round 2, 22 MDR related biological, 19 LDR related biological, 30 psychological and 10 social characteristics were endorsed as being important or essential for international podium success. Biological characteristics endorsed by all MDR experts included; capacity to run rounds, maximal aerobic speed, tactical awareness and capacity to recover from training. Biological characteristics endorsed by all LDR experts; capacity to tolerate high training loads, capacity to pace, maximal oxygen uptake, capacity to recover from training, running economy and efficiency. Psychosocial characteristics endorsed by all endurance-based running experts included; ability to cope with pressure, dedication, resilience, self-belief, coach-athlete relationship and training environment.

CONCLUSION: Findings highlight the importance of a biopsychosocial approach to the development of elite endurance-based runners. These findings may be useful in continuing to profile elite endurance-based runners to better inform athlete development. Ongoing efforts to use these findings to monitor athlete progression in an effort to differentiate between those who do and do not achieve podium success, is warranted.

THE SKILL OF SPEED: INSIGHTS FROM WORLD-CLASS SPRINT COACHES ON THE DEVELOPMENT OF SPRINTING TECHNIQUE

MASON, J., ZECH, A.

FRIEDRICH SCHILLER UNIVERSITY JENA

INTRODUCTION: Periodisation frameworks in individual sports describe the organisation of training to achieve physiological adaptations which drive improvements in key qualities such as strength, power and endurance. Few frameworks address the organisation of training for the acquisition of technique and skill, particularly in track and field. Therefore, the purpose of this research project was to elicit insights into the practices and perspectives of world class coaches regarding training design for the development of technique in sprinters.

METHODS: A qualitative research design was employed using semi-structured interviews. Seven elite sprint coaches were recruited. To be eligible, coaches must have coached at least one sprint athlete to qualification for a major international

championship. Questions related to micro and macro aspects of training designed to develop and refine sprint technique. Inductive thematic analysis was used to analyse the interview transcripts (Braun & Clarke 2006).

RESULTS: Emergent themes indicate that coaches commonly manipulate constraints to develop and refine sprint technique, including the use of sprint drills. All coaches deliberately target elements of sprinting technique multiple times per week during both preparation and competition cycles, although the temporal organisation and progression of this dedicated practice over time differs. Progressions in skill training are typically represented by increases in intensity or complexity. Multiple coaches articulated difficulties creating robust changes in technique which transfer to race performance. While coaches identified common objectives for different sprinting skills, some emphasized that there is no single model that they orient their athletes towards and instead combine their understanding of biomechanics with the unique characteristics of each individual to inform areas of focus and the subsequent prescription of training. Overall, coaches rely largely on experiential knowledge when prescribing technical training, and strategies to monitor and evaluate the outcomes of this training are varied and sometimes absent.

CONCLUSION: These insights reveal common approaches shared by elite sprint coaches regarding skill acquisition in sprinting, highlight the complexities of refining sprint technique and indicate an absence of clear framework for progressing technical training over time. This demonstrates a need for coaches to have a strong understanding of the general biomechanical features underpinning sprint performance to appropriately identify the needs of the athlete and subsequently accommodate and exploit their organismic constraints. Future research should build on traditional skill acquisition research to design ecologically valid models for the development of sprinting technique to maximise the transfer of training to race day.

A STUDY OF THE RESOURCES USED BY FOOTBALL TACTICAL ANALYSTS: THE ROLE OF DATA

CASTELLANOS, A.M., PORTILLO, C., COTERÓN, J., MON-LÓPEZ, D., MARQUINA NIETO, M., GARCÍA ALIAGA, A., REFOYO ROMÁN, I., MURIARTE SOLANA, D.
UNIVERSIDAD ALFONSO X EL SABIO ; UNIVERSIDAD POLITÉCNICA DE MADRID

INTRODUCTION: The role of the football-focused tactical analyst is a work area that has been in high demand in recent years (1). Key skills such as a broad knowledge of the game, being an expert in the interpretation of the opponents and ones own play, as well as strong observational skills are required (2). However, there is limited scientific information to be found on the processes of analysis and how they have incorporated eminently objective data in a profession with such an important subjective component. The study aims to analyse the resources used by analysts in their daily performance, as well as their relationship with data within the analysis process.

METHODS: The data collection was carried out employing semi-structured interviews, which were specifically designed for this field, being checked by 4 experts, and passing a pilot interview, being modified according to the feedback received. The inclusion criteria determined were (i) Spanish speakers and (ii) experience in first divisions or national teams. A total of 18 analysts participated in the study; to contact them, we used a first contact through social networks (LinkedIn, Whatsapp, Twitter,...) and then a snowball sampling, recommending colleagues who met these criteria. The interviews were conducted by video call, where the analysts allowed to record the content and its subsequent analysis. The content analysis was carried out by two researchers, triangulating the results with a third qualitative researcher.

RESULTS: The analysts subjective perception of the opposing team is the most reliable information for them, alluding to their experience to detect important aspects of them. The objective data can offer them a different perspective to the conclusion reached by them, or contrast their original idea, being an element of secondary consultation complained by the lack of general context. This may contrast with a social moment in performance analysis where it may seem that data is the most important factor in explaining performance. Likewise, there are minimal skills in video editing software, written reporting, and data provider consultation. They report no use of predictive game algorithms.

CONCLUSION: Tactical analysts rely more on their knowledge of game interpretation to develop their work, although they accept and value positively the use of the data, they do not believe it is blindly reliable due to the lack of context in which it is given.

IMPROVING SPORT SCIENCE IMPACT IN ATHLETE-LED PRACTICE ENVIRONMENTS: A TRACK CYCLING PERSEPCTIVE

STADNYK, A., IMPELLIZZERI, F., STANLEY, J., MENASPÀ, P., SLATTERY, K.
UNIVERSITY OF TECHNOLOGY SYDNEY

INTRODUCTION: Like most high performance sports, track cyclists are typically supported within the training environment by coaches and interdisciplinary practitioners who, using evidence-based practices, guide the athlete through the process of performance development. To effectively impact their practices and athlete performance, practitioners must be able to

implement their knowledge and expertise in a way that complements the wider performance team. The aim of this study was to examine track cycling coaches' perspectives of the role and impact of sport science and research on their practice and the athlete development process.

METHODS: Semi-structured interviews were conducted with elite track cycling coaches (n=8) who had been working at the highest level of the sport (Olympics, UCI World Championships). The interviews addressed factors contributing to athlete preparation, and the current and potential impact of sport science on the development of elite track cyclists. Reflexive thematic analysis was conducted to identify common themes in participants' experiences and perspectives.

RESULTS: Three principal themes were identified from the data: 'conversation & the information dynamic', highlighting the impact of information and feedback within the performance team for developing collective training intelligence; 'integrating performance components for the individual', detailing the importance of individualised and integrated approaches to athletes' performance needs; and, 'science to complement the vision', examining the value of filtered data, and limitations of research in practice.

CONCLUSION: The findings highlighted two key contributors to performance team effectiveness: athletes deeply invested in, and actively contributing to, the development process; and, performance staff identifying and filtering research and data to impact decision making and athlete development. A four-stage model was developed from the collective findings for guiding sport scientists' impact in athlete-led practice environments. Additionally, the model outlines sport scientist-supportive actions for coaches and athletes, along with practice-supportive actions for researchers, to improve impact within the sport.

THE DEVELOPMENT AND IMPLEMENTATION OF A FREIREAN-INFORMED WORKSHOP ON TRAINING LOAD AND MATURATION MONITORING PRACTICES WITHIN ACADEMY-LEVEL SOCCER CLUB ENVIRONMENTS

THOMPSON, N., HUGHES, J.D., DE STE CROIX, M.B.A., ROBERTS, W.M.
UNIVERSITY OF NORTHAMPTON; UNIVERSITY OF GLOUCESTERSHIRE

INTRODUCTION: Professional soccer academies frequently monitor training load and maturation to foster player development and mitigate injuries linked to growth (1). However, how training load and maturation monitoring data impacts coaching practice remains unclear. For both practices to be successful within club environments, it has been suggested that a collaborative, integrative approach between the key stakeholders should be employed (2). One potential solution to enhance training load and maturation monitoring practices is through employing interdisciplinary approaches (3) however, this may not be feasible for clubs with limited resources. This study adopted a Freirean-informed coach-practitioner workshop design to reflect on training load and maturation practices within each club environment and identify potential solutions to improve coaching practice .

METHODS: Youth development pathway staff from two Football Association category three academy clubs were purposively sampled (coaches, n=10; sport science practitioners , n=5). Coaches and practitioners initially reflected on training load and maturation monitoring practices within their club environment, and this consequently informed the development of the workshop. Within the 2-hour workshop , collaborative, reflective group discussions around five key statements evaluated practices of training load and maturation monitoring within each club environment. Each workshop was analysed using a deductive, reflexive thematic analysis .

RESULTS: Five higher-order themes were identified (coach biography, coach philosophy, communication of data to coaches, educating coaches and adapting monitoring practices). Coaches' biographies and philosophies appear to influence their acceptance and implementation of training load and maturation monitoring, suggesting a potential mismatch with current practices. An absence of an interdisciplinary environment, and the need for enhanced communication and education on training load and maturation monitoring data were consistently noted across both clubs. Resource limitations, particularly in human support and time constraints were identified as major barriers. In response, clubs have begun developing strategies to adapt their monitoring practices.

CONCLUSION: Individual coach biography and philosophy may have a significant impact on their approach to adopting and implementing training load and maturation monitoring practices. Although the workshop facilitated a collaborative, multi-disciplinary environment, it was evident that both clubs adopted a segmented approach to training load and maturation monitoring practices. Future research should aim to develop a collaborative, co-constructed club environment that facilitates coaches learning of training load and maturation monitoring practices.

OP-MH19 Physiotherapy II

THE EFFECT OF AN INNOVATIVE WARM-UP PROGRAM APPLIED BEFORE TRAINING ON THE PERFORMANCE OF AMATEUR SOCCER PLAYERS

VARHAN, B., GUNDAY, C., BAYKAN, Y.S., SOLAK, S., ALIYI, D., KARACIMEN, S.
ISTINYE UNIVERSITY

INTRODUCTION: The warm-up period is a common pre-exercise routine performed to transition from a resting state to the necessary preparation for a sports competition, increase performance and reduce the risk of injury. The traditional warm-up routine typically includes a short period of low-intensity aerobic exercise, followed by stretching and sport-specific exercise. The aim of this study was to investigate the effect of a dynamic innovative warm-up program applied to amateur soccer players on physical fitness parameters such as muscle strength, cardiopulmonary and muscular endurance, agility, balance and flexibility.

METHODS: 21 athletes (mean age; 22.65±1.18) and 21 sedentary individuals (mean age; 21.85±17) were included in the study. Muscle strength by hand-held myometer, vertical jump test and triple jump test; endurance levels with cooper 12 minute running test, lateral bridge test and sorenson test; agility with shuttle running test and square test; their balance was evaluated with the star balance test and their flexibility with the sit and reach test, trunk extension test and trunk flexion test. After the first evaluation, the athletes were taught the pre-training warm-up program and were asked to apply it 3 days a week for 8 weeks. The control group, consisting of healthy sedentary men, was asked to continue their normal lives. Assessments were repeated at the end of 8 weeks. The warm-up program consisted of foam rollers, dynamic stretching and elastic band traction applications.

RESULTS: The groups were homogeneous. A significant difference was found both within and between groups in the athletes in quadriceps femoris and hamstring muscle strength (bilateral), bilateral triple jump, Cooper running test, Sorenson test, shuttle running test, square test and sit and reach tests ($p<0.01$). There was no change in the control group.

CONCLUSION: This newly created warm-up program, focusing on dynamic stretching and flexibility, made positive contributions to the muscle strength, flexibility and performance of the athletes. In the light of these findings, the importance of warm-up protocols before training has been revealed and also warm-up sessions prevent injury it is recommended that similar studies be conducted in other sports branches.

ASSESSMENT OF CORE STRENGTH AND STABILITY CONTROL ABILITIES FOR MALE GYMNASTS BY USING HUBER® 360

XUE, L.
GENERAL ADMINISTRATION OF SPORT OF CHINA

INTRODUCTION: During past decades, the skills of gymnasts have become more complex and sophisticated in line with the evolution of Code of Point, gymnastics techniques and equipment. The proportion of gymnasts suffering from injuries is also increasing caused by high-intensity, high-load training. Both core strength and stability control are extremely important abilities to gymnasts, which not only affect the athletes specific techniques performance, but are also important factors in preventing sports injuries.

The purpose of this research is to measure the core strength and stability control abilities and identify the potential injury risks of high-level junior male gymnasts with using the Huber®360 platform.

METHODS: Sixteen high-level junior male gymnasts from China were involved within this study. The age, height, and weight of the study subjects are expressed in the form of M±D, which are 15.9±1.4 yr,159.3±9.6cm, and 52.1±8.3kg respectively. Inbody 720 was used to measurement the body composition of the subjects. HUBER®360was the instrument used in this research, which is a device with an oscillating platform and two handles, as well as force sensors situated beneath the motorized platform and at the handle level. The Huber 360 software can be used for objectively assessment with a series of seven functional tests. According to the study purpose and objectives, out of the 7 tests, we shall only use two tests, the Stability limit test and Maximum strength test.

RESULTS: All the study subjects completed all the tests.

1. Body composition. The average body fat percentage of the 16 gymnasts is 5.4±2.7% (range from 3.0% to 12.0%), which is an excellent data for male gymnast. The low level of body fat percentage is not only the result of long-term training, but also the specific requirement of gymnastics. From the perspective of muscle mass distribution, there is no difference in muscle mass of the group of gymnasts investigated between the left and right upper limbs (3.0±0.7kg,3.0±0.7kg) and lower limbs (7.1±1.3kg,7.1±1.3kg).

2. Stability limit test. Considering the comparison of symmetry in the diagonal direction, the result demonstrated that four subjects showed diagonal advantage characteristic, that is, the data of result are very symmetrical in all four diagonal directions. Seven subjects showed a medium symmetrical in most diagonal directions. Four subjects showed unilateral dominance characteristic, the right side result of three of them is larger than left, and the other one is opposite. Only one subject showed relatively big differences between the front and back side.

3. Maximum strength tests. Considering the unilateral maximum strength difference between the push and pull, and the maximum strength difference of push (or pull) between the left and right side, the result demonstrated that five subject showed perfect balance in the comparation of unilateral or bilateral strength. Seven subjects' results showed that the bilateral strength is balance,

CONCLUSION: The study describes a preliminary test conducted on sixteen high-level junior male gymnasts with the HUBER®360platform. The tests and the findings are of great significance, which not only give suggestion that some gymnasts may be at risk for injury due to strength imbalances, and also point out the direction of next-step training.

UNDERSTANDING PHYSICAL THERAPISTS PERCEPTIONS OF ENGAGING IN PHYSICAL ACTIVITY PROMOTION

KENNEDY, W.

NORTHEASTERN UNIVERSITY

Introduction

Physical therapists (PTs) work with diverse populations to promote function, activity participation, and quality of life. PTs are also positioned to provide physical activity (PA) promotion; however, it has been suggested that they do not consistently do this with their patients. Investigation into barriers to including PA promotion in PT clinical practice have found that knowledge, time and resources are consistent barriers. One important consideration that has not been included in this area of research is how PTs conceptualize PA promotion in clinical practice. Understanding how PTs conceptualize PA promotion can lead to the development of strategies and tools to increase the consistency in which PA promotion is implemented in clinical practice.

Methods

Semi-structured virtual interviews were conducted. Participating licensed PTs were purposively recruited from a national survey sample to reflect diverse demographics and professional settings in the United States. Participants were given a list of PA promotion approaches that were considered typical within PT practice, and then asked to provide feedback. Inductive thematic analysis was used for qualitative analytical approach. Trustworthiness was established by use of reflexivity, triangulation, and memos to serve as an audit trail.

Results

A total of 10 participants completed the interviews. Most of the sample worked in outpatient clinical settings. The sample was evenly split between PTs working primarily with adults and those working primarily with children. There were two overarching themes that emerged from the interviews. 1) Specific guidelines on PA promotion are needed and should be tailored to specific clinical settings and patient populations; and 2) PTs should be leaders in PA promotion but must become better at it. Additional themes include the process of engaging in PA promotion and access to community resources also emerged.

Discussion

The findings revealed that participants have a wide range of perspectives on what PA promotion is. PTs expressed lacking some knowledge on how to promote PA wholistically. For example, when participants were given several ways that they could promote PA, they were only familiar with some of the suggestions. Participants did express that all of the suggestions were appropriate for the clinical setting and can support their patients in engaging in PA. Further, some participants recommended that PA promotion guidelines that are tailored to specific patient populations and clinical settings would support engaging in PA promotion with their patients. Participants believed that PTs should be leaders in clinical PA promotion but acknowledged that support is needed to ensure that they can engage in it efficaciously. The findings of the study implicate that to support the PA promotion in PT clinical settings, specific guidelines are needed to support knowledge and skill development, which in turn support PTs becoming leaders in clinical

THE EFFECT OF TOTAL SLEEP DEPRIVATION ON LOWER EXTREMITY ECCENTRİC MUSCULAR STRENGTH AND ACTIVATION

GURUHAN, S.1, ATALAY, N.A.1, HIRATA, R.2, ANDREUCCI, A.2, TOR, O.B.1, RATHLEFF, M.S.2

1. GAZI UNIVERSITY, DEPARTMENT OF PHYSIOTHERAPY AND REHABILITATION, ANKARA/TURKEY. 2. AALBORG UNIVERSITY, DEPARTMENT OF HEALTH AND TECHNOLOGY, AALBORG/DENMARK.

INTRODUCTION: Sleep is an essential component for optimizing health and sports performance. It has been reported, however, that athletes experience more sleep disturbances than non-athletes [1,2] For athletic performance, it is important to study how total sleep deprivation (TSD) affects eccentric contraction, which plays a major role in increasing strength and hypertrophy and preventing injuries [3]. The aim of this study was to investigate the effects of TSD on eccentric muscle strength and activation in hamstring and quadriceps.

METHODS: Twenty-one recreationally active individuals (10 males and 11 females, 21,05±1,46 year, 21,99±2,89 kg/m2) with good sleep quality (Pittsburgh sleep quality index and 5-point Likert scale) were enrolled in the crossover study. Each participant performed two test sessions with a 2-week washout period. The first test was performed in 2 hours after waking up. The second test was performed at the same time with the first one after 24 hours of sleep deprivation. The participants performed 5 repetitive eccentric contractions (900/s) using the isokinetic system for hamstring and quadriceps muscle groups in both prone and supine positions, respectively. Surface electromyography (Noraxon Inc., USA) was used to record the activation of the Biceps femoris (BF), Semitendinosus (ST), rectus femoris (RF), vastus lateralis (VL) and vastus

medialis (VM) during eccentric contractions. The peak torque and muscle activity was calculated for statistical analysis using 2nd, 3rd and 4th repetitions of each test.

RESULTS: There was no statistically significant difference between normal sleep and sleep deprivation states in terms of eccentric muscle strength of hamstring (p=0.088) and quadriceps (p=0.304) muscles, however, a decremental trend was observed. The muscular activation of the VL muscle during the isokinetic eccentric exercise test decreased significantly (p=0.045) in the sleep deprivation state compared to the normal sleep state, while there were no significant differences between normal sleep and sleep deprivation states in terms of muscular activation of the RF, VM, BF and ST muscles (p>0.05).

CONCLUSION: Our study showed no differences in the eccentric strength of hamstrings and quadriceps muscle groups, however, a decrease in the activation of VL following a 24-hour-sleep deprivation. Therefore, eccentric exercise programs may be more tolerable in the morning hours and show muscle specificity in TSD.

NORDIC WALKING TRAINING AND DETRAINING EFFECTS ON FUNCTIONAL STATUS, PERCEIVED FATIGUE, AND QUALITY OF LIFE IN PERSONS WITH MULTIPLE SCLEROSIS

LIBERALI, G., MARTINIS, L., CORREALE, L., DELL'ANNA, S., FILOSA, A., MACHADO, F.A., TAVAZZI, E., BERGAMASCHI, R., PEYRÉ-TARTARUGA, L.A., BUZZACHERA, C.F., MONTOMOLI, C.

UNIVERSITY OF PAVIA, ITALY;STATE UNIVERSITY OF MARINGÁ, BRAZIL;MULTIPLE SCLEROSIS RESEARCH CENTRE, NATIONAL NEUROLOGICAL INSTITUTE CASIMIRO MONDINO,ITALY;FEDERAL UNIVERSITY OF RIO GRANDE DO SUL,BRAZIL

Abstract

Multiple Sclerosis (MS) is a chronic neurologic disease characterized by motor dysfunction, cognitive impairment, and a pronounced impact on quality of life. Common symptoms include fatigue, ataxia, tremors, spasticity, paralysis, and pain, which often compromise functional aspects such as balance and walking capacity. Non-pharmacologic interventions, such as exercise training, are recommended for individuals with MS and may help alleviate disease-related symptoms. Nordic Walking (NW) is a popular mode of exercise involving walking with hand-held poles. Despite its growing popularity, there is no published evidence on the NW training effects in the MS population. Hence, the present study investigated the NW training and detraining effects on functional status, perceived fatigue, and quality of life in persons with MS.

Methods

Fifteen individuals (4 men and 9 women; mean age: 44 ± 11 yr) with definite relapsing-remitting MS (EDSS score < 4) met the inclusion and exclusion criteria and were enrolled in this study. They were trained twice weekly for 8 weeks, followed by 12 weeks of detraining. All participants were tested before and after the intervention period and after training cessation (follow-up). Aerobic endurance (2-min walk test), upper- (handgrip) and lower-body (30-sec chair stand test) muscle strength, gait speed (10-m walk test), and overall functional mobility (timed up and go test) were tested. Perceived fatigue (Modified Fatigue Impact Scale) and quality of life (MS Quality of Life Questionnaire) were also evaluated.

Results

The adherence rate was as high as 81%. There were significant changes in aerobic endurance, lower-body muscle strength, overall functional mobility, and gait speed following the NW intervention ($P < 0.05$). These changes persisted after training cessation ($P > 0.05$). In contrast, upper-body muscle strength did not change following the NW intervention ($P > 0.05$). While quality of life did not change over time ($P > 0.05$), perceived fatigue was reduced following the NW intervention ($P < 0.05$). These changes in perceived fatigue, however, did not persist after training cessation ($P > 0.05$).

Conclusion

Our results suggest that eight weeks of NW training improves functional status, perceived fatigue, but not quality of life, in individuals with MS. Some favorable changes persisted even after training cessation. Such findings encourage exercise professionals and other healthcare providers to support NW training as a feasible and safe approach in the MS population.

Re-imagining self-compassion: A healthy, effective pathway to mental toughness and performance under pressure

Shuge Zhang1,2*, Yutao Zho2,3, Luke Gibson1, Kirsten McEwan4

1 School of Sport & Exercise Sciences, University of Derby, UK

2 Hunan Research Centre of Excellence in Fitness, Health & Performance, China

3 College of Physical Education, Hunan University of Technology, China

4 School of Psychology, University of Derby, UK

Background: Mental toughness is commonly used to describe an athlete who strives to excel and fulfil set goals despite challenges. It involves a collection of personal recourses such as self-efficacy and optimism and reflects the ability to maintain or enhance performance under high pressure. However, traditional mental toughness training has largely focused on enriching athletes' personal resources such as mental skill use or enhancing threat detection and the ability to maintain high-level performance under pressure. Given the benefits of self-compassion in emotional regulation under difficult times in sport, in this project, we aimed to establish new evidence supporting the usefulness of a self-compassionate approach in fostering mental toughness in competitive athletes by taking a novel approach examining the interaction of athletes' self-compassion and fears of compassion in mental toughness.

Methods: Among 281 competitive athletes from 24 sports (Study 1) and 253 professional footballers from 12 teams (Study 2), we examined the interaction between athletes' self-compassion and fears of compassion on self-report (Studies 1 and 2) and coach informant rating of athletes' mental toughness and ability to maintain high-level performance under pressure (Study 2).

Results: Multilevel (clustered) moderation analysis demonstrated a positive link between self-compassion and mental toughness (regardless of self-report or coach rating), of which the relationship was stronger when fears of compassion in sport were low, not high. The negative influence of low self-compassion on mental toughness levels was amplified greater when fear of self-compassion (compared to when fear of receiving compassion from others) was low. Such results were consistent in the multisport sample (Study 1) and the professional football sample (Study 2).

Conclusion: The findings provide the first quantitative evidence of the facilitative role of interaction between self-compassion and fears of compassion in athletes' mental toughness. Incorporating self-compassion is not only a way to realise better mental well-being and enhanced morality in sport but also an effective strategy for performance enhancement. Sport organisations, coaches, and practitioners should consider incorporating a self-compassionate approach to developing athletes' mental toughness.

THE EFFECTS OF CONNECTEDNESS TO NATURE ON THE BENEFITS OF GREEN EXERCISE

ZHANG, D., LI, W., JIN, Y.

ZHEJIANG NORMAL UNIVERSITY

Introduction

Green exercise has been widely shown to provide synergistic benefits than those from exposure to other environments or from engaging in physical activity alone or being in a natural environment alone. Much of the literature has emphasized the importance of the positive effects of exposure to nature, which are affected by high connectedness to nature (CNT). Yet few studies have explored the effect of CNT on the benefits of green exercise. This study examined whether the differences of CNT in individuals play a role on exercise benefits, which is helpful to choose the suitable environment for recovery and exercise.

Methods

100 healthy college students were recruited through an advertisement at the university campus to answer a Connectedness to Nature Scale (Mayer & Frantz, 2004). Participants scoring in the top 27% were invited as the high-CNT group (14 females and 11 males), whereas participants scoring in the bottom 27% were invited as the low-CNT group (12 females and 11 males). Participants engaged in incremental cycling exercise at a moderate intensity while viewing images of nature or urban environments. Before and after cycling (test time), Chinese versions of the Profile of Mood States scale and the Rosenberg Self-Esteem Scale, and a two-choice oddball task were completed respectively.

Results

Significant interactions for environment × test time indicated that lower post-test scores in total mood disturbance, tension, fatigue subscales and higher score in vigor subscale in the natural environment condition than in the urban environment condition. An interaction for group × environment × test time showed that the high-CNT group has a significantly increased self-esteem scale scores after cycling in the natural environment, but not in the built environment, while the low-CNT group has a significantly increased self-esteem scale scores in both environments. The significant interactions for group × environment showed that the high-CNT group reports more Being Away and Fascination and Compatibility than the low-CNT group in the natural environment, and less Extent than the low-CNT group in the urban environment.

Discussion

Our results suggest that green exercise improves mood, self-esteem, and restorative experiences. Furthermore, individuals with high-CNT receive more exercise benefits in natural environments. This result might be attributed to feelings toward the natural environment. Individuals with high-CNT are closer to nature and have more positive feelings towards the natural environment, which can lead to more exercise benefits. On the other hand, individuals with high-CNT are less attracted to the urban environment and even report more negative feelings, which might impact the exercise benefits in the urban environment.

"WHY I MEDITATE?": ELITE ATHLTES' PERSPECTIVES OF USING MINDFULNESS DURING COMPETITION

LO, K.K.1, CHUNG, J.W.Y.2, SUN, F.3

1.HONG KONG SPORTS INSTITUTE; 2.KIANG WU NURSING COLLEGE OF MACAU; 3.THE EDUCATION UNIVERSITY OF HONG KONG

INTRODUCTION: Mindfulness training has shown promise in enhancing performance by reducing anxiety and increasing mindfulness and flow in elite athletes. However, there is limited understanding of how mindfulness techniques are specifically implemented during competitions. This qualitative study aims to explore the experiences of elite athletes participating in a mindfulness flow program (MFP). The research project has two primary objectives: (1) investigating the application of mindfulness during competition and (2) gathering participants recommendations and suggestions for future iterations of mindfulness-based interventions.

METHODS: A qualitative descriptive research design was employed, utilizing semi-structured interviews (Sandelowski, 2010). Twelve archers, including five who participated in the Asian Games, with an average experience of 8.9 ± 3.3 years, were recruited. Interviews were conducted after a 12-week intervention of the mindfulness flow program (MFP). Transcripts were analyzed inductively using an iterative process of reflexive thematic analysis (Braun & Clarke, 2022).

RESULTS: The qualitative findings revealed that athletes applied mindfulness practices during both practice and competition, such as "awareness of body sensation" to maintain balance in outdoor environments. Athletes engaged in exercises focusing on balance, such as standing on one leg or blindfolded practice, to enhance their body awareness. Adjustments were made based on observed differences between each shot to maintain the desired center of gravity, while accounting for external factors like wind. Moreover, athletes reported reduced reactivity to negative thoughts during competitions. Regarding intervention delivery preferences, half of the participants expressed a preference for face-to-face sessions, while others favored online-mode to save travel time. Shorter sessions (e.g., 60-75 minutes) over an extended period were preferred, with classes scheduled to avoid conflicts with sports-specific training.

CONCLUSION: This study provides valuable insights into the practical application of mindfulness techniques by athletes during competitive situations. Understanding the diverse ways mindfulness can be employed can assist psychologists and sports scientists in providing coaches with timely and relevant information to enhance athletes performance. Future research should explore how world-class athletes utilize mindfulness to enhance performance, examine the coach-athlete relationship, and investigate the broader impact of mindfulness on athletes daily lives.

THE EFFECTIVENESS OF GROUP-BASED RATIONAL EMOTIVE BEHAVIOR THERAPY (REBT) AND MINDFULNESS-BASED INTERVENTION (MBI) ON PERFECTIONISM AND EXECUTIVE FUNCTIONS AMONG HUNGARIAN ATHLETES

TÓTH, R., TURNER, M.J., MANNION, J., TÓTH, L.

HUNGARIAN UNIVERSITY OF SPORT SCIENCE

Introduction

In our research, we examined the effectiveness of Rational Emotive Behavior Therapy (REBT) and mindfulness-based interventions (MBI) concerning athletes perfectionism and executive functions. REBT focuses on identifying irrational beliefs and restructuring them to be more rational, while mindfulness aims to achieve acceptance and non-judgment through conscious presence. The main goal of our study was to uncover how group-based REBT and mindfulness interventions impact perfectionism, as well as executive functions (working memory, inhibition, cognitive flexibility) among athletes.

Methods

In our longitudinal study, a total of 46 Hungarian ice hockey players participated, with 12 individuals forming the REBT group, 14 in the mindfulness group, and 20 in the control group. Perfectionism was measured using the Short Almost Perfect Scale (SAPS), while executive functions were assessed using the computer-based Vienna Test System before and after the interventions. We analyzed our data using repeated measures analysis of variance (ANOVA).

Results

Our results indicate that athletes in the REBT group show significant decreases in both adaptive and maladaptive perfectionism after the interventions, along with improvements in inhibitory functions and cognitive flexibility test scores in the post-tests compared to the pre-tests. Members of the mindfulness group do not show significant differences in perfectionism before and after the interventions. However, they demonstrate improvements in information processing speed and in switching functions (cognitive flexibility). In the control group, there is a significant decrease in the speed of the test measuring cognitive flexibility in the post-tests compared to the pre-tests.

Discussion

Consequently, the restructuring of athletes irrational beliefs towards rationality can assist in reducing perfectionistic tendencies and contribute to the development of neurocognitive functions that could positively impact their athletic performance. Similarly, mindfulness-based intervention can enhance cognitive flexibility, thus contributing indirectly, if not

directly, to both mental health improvement and athletic performance. These findings could prove beneficial in shaping future research directions and expanding the toolbox of applied sports psychology.

Exchange Symposium

IS-EX01 ACSM-ECSS Exchange Symposium: High-Intensity Interval Training in the Prevention and Treatment of Cardiometabolic Disease

HIGH INTENSITY INTERVAL TRAINING IN HEALTH AND DISEASE

GIBALA, M.
MCMASTER UNIVERSITY

This presentation will consider evidence regarding the physiological basis of responses to high-intensity interval training to enhance health, with a focus on cardiorespiratory fitness and glycemic control. Emphasis will be placed on the role of brief, vigorous intermittent physical activity including emerging evidence regarding the efficacy of "exercise snacks" in both healthy individuals and those living with cardiometabolic disease.

HIGH INTENSITY INTERVAL TRAINING, THE PROS AND CONS

HALLE, M.
TECHNICAL UNIVERSITY MUNICH

This presentation will discuss the clinical role of high-intensity interval training versus moderate continuous training in different cardiovascular patient populations addressing coronary heart disease, heart failure and atrial fibrillation, particularly addressing clinical outcomes including morbidity and mortality.

Invited Symposium

IS-BM02 Explosive performance: lessons from the animal kingdom, from new testing paradigms, and from space

EXPLOSIVE STRENGTH: WHAT WE CAN LEARN FROM THE HIGH-PERFORMANCE OF ANIMALS

RUGGIERO, L.
UNIVERSITY OF KONSTANZ

Explosiveness is the ability to develop the greatest amount of force in the minimum time. This quality is key in the context of sport performance or physical activity, should the aim be to jump higher or sprint faster than competitors, to recover performance after an injury, or to avoid functional loss as consequence of immobilization, muscle disuse, or aging. To understand what makes people accelerate or decelerate faster, the spotlight is often on high-performance athletes, due to their amazing physical capabilities and resiliency. Sometimes however we overlook examples of explosive high-performance in Nature, a parallel world where Humans can learn from. In such cases, it is not about winning a medal, rather about predation and escape. Still, stakes are very high. In this presentation I will unravel the mechanisms of some of the most astonishing explosive performances in Nature, relating them to Humans, and to the lessons that we can learn out of it for the improvement of our rapid force production capacity. First, I will represent where the explosive capabilities of Human athletes stand in relation to other animals. As it can be guessed, we are not the strongest, but neither the weakest. I will then use the case of standing jumps as a model of explosive force from a static starting condition. To jump as high as possible, evolution has developed two main (divergent) mechanisms: the spring- (or latch-) and the muscle-mediated actuation. What if Humans jumped with a spring-actuated mechanism? And what if they did with a muscle-actuated mechanism? What do explosive force and jump height depend on in the two modes of actuation? And what are the drawbacks of using each mode? Such hypotheses and comparisons can shed light on the determinants of human explosive performance. Finally, I will present an example of a more dynamic situation in Nature to show how Biology can directly help sport-related outcomes. This example regards two seemingly different but congruent mechanisms in explosive performance: the predator-prey interaction in the wild and the change of direction in sport. As sport scientists and practitioners, typically we are not biologists. However, both animal- and sport-related movements are based on biological (common) principles. Some animals have exploited these principles to be high performers in their own habitat. Thus, interacting with Biology, while on one side may not provide in the short-term a performance-enhancing winning solution, may provide a framework to better understand the determinants of Human performance.

THE ROLE OF SYNAPTIC INPUTS TO MOTONEURONS IN DETERMINING RATE OF FORCE DEVELOPMENT

ŠKARABOT, J.
LOUGHBOROUGH UNIVERSITY

The motor units, comprised of the alpha motoneuron and all the muscle fibres it innervates, are the most basic elements of the neuromuscular system that transduce the summated synaptic inputs into twitches of individual muscle fibres. The key determinants of rate of force development are motor unit recruitment speed and discharge rate of the recruited motor units. The deterministic role of motor unit discharge rate characteristics in rate of force development underscores the importance of the properties of, and the synaptic input received by the motor pool in rapid force production. In the first part of this talk, I will first show computational and experimental evidence supporting the hypothesis that motor pool characteristics are directly implicated in the rate of force development of a given muscle. Specifically, I will demonstrate that the upper limit of motor unit recruitment in a given motor pool is linked to recruitment speed of motor units, and consequently, the rate of force development. In the second part of the talk, I will explore the neural substrate(s) underpinning the fast recruitment speed and high discharge rate of motor units underpinning rapid force production. I will introduce the importance of excitatory ionotropic inputs to motoneurons from the reticular formation in the brainstem, with experimental evidence suggesting the importance of augmenting the excitatory input to motoneurons via reticulospinal pathway to increase rate of force development and strength. Lastly, I will focus on the interaction of motor unit discharge characteristics and motor unit twitch properties when generating maximal rate of force development using a model of chronically resistance-trained and endurance-trained individuals that confer different adaptations to the neural and muscular system.

RAPID FORCE PRODUCTION IN REACTIVE MOVEMENTS: JUMPING WITH VARIABLE GRAVITY INDUCED STRETCH LOADS

WALDVOGEL, J.
UNIVERSITY OF FREIBURG

Explosive movements such as sprinting and jumping require a finely tuned coupling of eccentric and concentric muscle actions. It is known that stretch-shortening cycle (SSC) type actions require a well-tuned and pre-activated muscle-tendon unit (MTU), a short eccentric phase, and an immediate coupling of eccentric and concentric phases to develop high forces in a limited amount of time, to enhance reactive jump performance and to maximize energy storage and release. For meeting such criteria a perfectly coordinated interplay between the central nervous system (CNS) and the MTU is mandatory. The CNS regulates the MTU's stiffness by modulating the muscle activity prior and during ground contact, and such regulation is phase-, task- and stretch load-dependent. Previous experiments have predominantly used biomechanical methods such as electromyographic recordings, kinematics and kinetics to investigate the underlying mechanisms of SSC type actions. Technological advances such as ultrasound technique revealed direct insights into the muscle function and muscle-tendon interaction during dynamics. Furthermore, in many sports, as well as during human locomotion, requirements and environmental conditions are not necessarily constant and may change even rapidly. To functionally understand how the CNS and the MTU interaction are challenged by variable conditions, this presentation provides an overview of past and current studies investigating the effect of variable stretch load on the neuromuscular control and MTU interaction during reactive explosive movements. In such studies, the effect of variable stretch loads are limited to loading and unloading scenarios of +/- 20-30% of body weight. Stretch loads beyond these limits are normally experimentally challenging and associated with confounding effects. In contrast, parabolic flights are a unique paradigm to induce stretch loads ranging from 0.1 to 2g (-90% to +100% body weight), allowing near-natural movement execution. This presentation also provides an overview of existing parabolic flight experiments which aimed to investigate stretch load dependent modulations at the neuromuscular and muscle mechanical level. Furthermore, biomechanical and energetic consequences will be highlighted. Given the implications of overloading and unloading in weight and velocity-based trainings to enhance explosive force production, this presentation is of high scientific interest for sport scientists, coaches, athletes, as well as other practitioners. Findings from parabolic flight campaigns regarding rapid force production in overloading and unloading conditions may also inform other practitioners such as engineers in the interface with sport science.

OP-PN19 Fatigue II

INDIVIDUAL DIFFERENCES IN MENTAL FATIGUE RESPONSE: THE ROLE OF BASELINE COGNITIVE FUNCTIONS

SCHAMPHELEER, E., HABAY, J., PROOST, M., ROELANDS, B.
VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: Mental fatigue (MF) is defined as a psychobiological state induced by prolonged demanding cognitive activity [1]. It induces a subjective feeling of fatigue [2] and has implications for both physical and cognitive performance (e.g. impaired endurance and attention) [1, 3]. However, the level of emergence of MF is highly variable between individuals. Almost no factors have reliably been identified that can predict the response to MF [4]. Therefore, this study aimed to elucidate whether baseline cognitive functions could predict the susceptibility to MF and its impact on performance.

METHODS: We employed a randomized, single-blinded, counter-balanced, cross-over research design. Ninety-seven healthy participants (53 male, 32.7 ± 8.7 y) initially completed three cognitive tests (sustained attention to response task, psychomotor vigilance task, and N-BACK task) assessing their cognitive functions (attention, working memory, and response inhibition). In the experimental and control trial, participants respectively engaged in either a 45-minute Stroop task or documentary. Pre- and post-trial, participants rated their feeling of MF using a visual analogue scale (M-VAS). Post-trial, they completed a Go-NoGo task and a 15-minute cycling time trial to evaluate cognitive and physical performance. Linear regression was used to evaluate the relationship between cognitive abilities and MF effects.

RESULTS: Baseline cognitive functions did not significantly relate with M-VAS scores (F=1.527; p=.204; R2=.029) or the extent to which MF affects physical performance (F=.591, p=.670; R2=-.019). Additionally, baseline cognitive functions could not predict the effect of MF on cognitive performance, including reaction time on the Go stimuli (F=.647; p=.630; R2=-.016) and accuracy on both the Go (F=2.024; p=.098; R2=.044) and NoGo (F=1.594; p=.183; R2=.026) stimuli.

CONCLUSION: Baseline cognitive functions do not appear to reliably forecast susceptibility to MF or its effects on performance in healthy individuals. More research is needed to fully elucidate the individual response to MF, identify individuals who are more prone to MF and to develop targeted interventions.

PREFRONTAL CORTEX OXYGENATION DURING A MENTALLY FATIGUING TASK IN NORMOXIA AND HYPOXIA.

ROOSE, M., DE WACHTER, J., PROOST, M., HABAY, J., VERSTRAELEN, M., DE PAUW, K., MEEUSEN, R., ROELANDS, B.
VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: Mental fatigue (MF) arises from extended periods of demanding cognitive activity and impairs cognitive and physical performance [1]. Hypoxia is another stressor known for impairing performance. Typically, changes in cognitive and physical functioning at altitude are associated with alterations in brain oxygenation [2]. These changes are preferably measured in the prefrontal cortex (PFC), renowned for its role in higher-level cognitive function [2]. Therefore, we aim to examine whether oxygenation of the PFC plays a role in the development of MF.

METHODS: Twelve participants (age 22.9 ± 3.5 y; height 174.2 ± 8.2 cm; mass 69.9 ± 13.9 kg) completed four experimental trials, 1) MF in (normobaric) hypoxia (3.800m; 13.5%O2), 2) MF in normoxia (98m; 21.0%O2), 3) Control task in hypoxia 4) Control task in normoxia. Participants performed a 2-back task, Digit Symbol Substitution test and Psychomotor Vigilance task before and after a 60-min Stroop task or an emotionally neutral documentary. Brain oxygenation was measured through functional Near Infrared Spectroscopy. Subjective feelings of MF and physiological measures (heart rate, oxygen saturation, blood glucose and hemoglobin) were recorded. A 2 x 2 x 5 three-way repeated-measures ANOVA [Mental State (MF, CON) X FIO2 (normoxia, hypoxia) X Time (baseline, block 1, block 2, block 3, block4)] was used for the MVAS, fNIRS and Stroop task ACC and -RT. For data from the 2BACK, DSST, PVT, SaO2 Mood and BVAS, a 2 x 2 x 2 three-way repeated-measures ANOVA [Mental State (MF, CON) * FIO2 (normoxia, hypoxia) * Time (pre, post)] was performed.

RESULTS: The Stroop task resulted in increased subjective feelings of MF ($F(1.6, 16.2) = 19.3$, $p < 0.001$) compared to watching the documentary ($F(1.6, 15.5) = 6.3$, $p= 0.014$). 2-back accuracy was lower post task compared to pre task in MF_NOR and CON_NOR (PRE: 87.1 ± 7.72, POST 75.70 ± 12.88), while no differences were found in the other cognitive tasks. The fraction of inspired oxygen did not impact feelings of MF. Although performing the Stroop resulted in higher subjective feelings of MF, hypoxia had no effect on the severity of self-reported MF. Additionally, no evidence could be provided for a role of oxygenation of the PFC in the build-up of MF.

CONCLUSION: The role of PFC-oxygenation during the build up to MF and the associated interaction effects with altered oxygen availability were investigated within this study. Although MF was successfully induced, normobaric hypoxia seemed to have no effect on the severity of self-reported MF and subsequent cognitive function. Additionally, no evidence could be provided for the role of PFC oxygenation during a MF task.

IMPACT OF REPETITIVE MAXIMAL COUNTERMOVEMENT VS. SQUAT JUMPS PERFORMED UNTIL EXHAUSTION ON MOTOR PERFORMANCE FATIGUE OF THE QUADRICEPS MUSCLE AND ITS NEUROMUSCULAR UNDERPINNINGS

BEHRENS, M., HUSMANN, F., WEIPPERT, M., FELSER, S., BIELITZKI, R., BEHRENDT, T., SCHEGA, L., BRUHN, S., GUBE, M.
UNIVERSITY OF APPLIED SCIENCES FOR SPORT AND MANAGEMENT POTSDAM

INTRODUCTION: The countermovement jump (CMJ) and squat jump (SJ) are two basic movements that are required during physical activities and are used to monitor human performance. CMJ height is almost always greater than SJ height and the difference is thought to reflect the efficiency of utilizing the slow stretch-shortening cycle (SSC). The mechanisms contributing to the performance enhancing effect of the SSC include history-dependent muscle properties, recoil of elastic energy, pre-activation, and stretch reflexes. Although studies have investigated the mechanisms of the jump-dependent differences in performance, hardly any data exists on the effect of repetitive maximal CMJ and SJ performed until exhaustion on motor performance fatigue of the quadriceps muscle (i.e. decline in isometric maximal voluntary torque (IMVT)) as well as its neural (i.e. voluntary activation) and muscular (i.e. contractile function) underpinnings. It was assumed that a lower number of repetitions will be achieved in the CMJ compared to the SJ condition, with unique SSC-dependent neural and muscular adjustments.

METHODS: In a randomized, counterbalanced, crossover design, 14 males performed repetitive maximal CMJ and SJ every 4s until exhaustion, defined as a drop in jump height by 50%. Using peripheral electric nerve stimulation and dynamometry, neuromuscular function was assessed before and after exercise during each condition to analyze the impact of jump type (CMJ, SJ) on motor performance fatigue and its neural and muscular determinants. Additionally, mean heart rate (HR), blood lactate concentration (BLC), and effort perception were recorded during exercise. Motor performance fatigue as well as its neural and muscular determinants were quantified as percentage pre-post changes in IMVT (ΔIMVT), voluntary activation (ΔVA), and quadriceps twitch torque evoked by paired electrical stimuli at 100 Hz (ΔPS100), respectively.

RESULTS: Participants tended to perform fewer repetitions during CMJ compared to SJ (CMJ: 510±164, SJ: 663±308, p=0.081), while HR (CMJ: 165±15bpm, SJ: 164±17bpm, p=0.410), BLC (CMJ: 4.1±2.3mmol/l, SJ: 3.8±3.0mmol/l, p=0.370), and effort perception (CMJ: 16.5±1.7, SJ: 16.8±1.0, p=0.455) were similar between conditions. Furthermore, no differences between conditions were found for ΔIMVT (CMJ: -29.1±17.5%, SJ: -25.7±8.5%, p=0.429), ΔVA (CMJ: -30.4±21.4%, SJ: -34.9±16.7%, p=0.380), and ΔPS100 (CMJ: -16.4±20.8%, SJ: -22.7±19.9%, p=0.296)

CONCLUSION: Participants tended to perform a lower number of CMJ compared to SJ, while indices of internal load (HR, BLC, effort perception), motor performance fatigue, and the decrease in neuromuscular function were comparable between conditions. This might be related to the involvement of the slow SSC, which resulted in a greater jump height and mechanical strain during the CMJ, probably leading to an earlier exercise termination accompanied by the same extent of motor performance fatigue and neuromuscular impairments.

NEUROMUSCULAR ENDURANCE AND FATIGABILITY: SEX DIFFERENCES IN CHILDREN AND YOUNG ADULTS

LEDERGERBER, R., LICHTENSTEIN, E., ROTH, R.
EXERCISE AND TRAINING SCIENCE

INTRODUCTION: Prepubertal children exhibit distinct neuromuscular characteristics when compared to adults, including reduced voluntary activation and fatigability, and a possibly lower recruitment of larger motor units that innervate predominantly fast-twitch fibers (1,2). Depending on exercise modality, childrens fatigue is also more pronounced centrally rather than peripherally (1). Additionally, there is evidence that females may experience less fatigue than males, though studies focusing on this aspect in children are sparse (3). Hence, this study was designed to examine neuromuscular differences by age and sex in knee extensor muscle endurance until failure.

METHODS: A cohort of 23 prepubertal children (9.4±0.9y) and 23 adults (23.4±2.4y, 54% F), undertook a maximal voluntary isometric contraction (MVCpre), a task to failure at 60% of MVCpre, and a subsequent MVCpost in knee extensors. Surface electromyography (EMG) was recorded for the rectus femoris (RF), vastus medialis (VM), and vastus lateralis (VL) at 0, 25, 50, 75, and 100% of individual time to failure (TTF). Age and sex differences were quantified for TTF, MVCpre-post, and the root mean square (RMS) and median frequency (MDF) values of the EMG signals using linear models and Cohens d effect sizes.

RESULTS: Moderate age-related differences were noted in TTF (d=-0.54), along with a large age*sex interaction (d=1.06). Children experienced a greater change in MVCpost (d=0.42), with negligible age*sex interactions (d≤0.2). At the onset of the trial (0% TTF), children showed less activation in all muscles (d≥1.18), and as the failure-task progressed, age-related differences were observed in the RMS and MDF for RF, VL, and VM (d≥0.14), with minimal differences attributable to sex and age*sex interaction (d≤0.19).

CONCLUSION: Childrens reduced capacity to produce MVCpost and the smaller changes in EMG readings could indicate a dominance of central over peripheral fatigue. This is further suggested by the lower initial muscle activation in adults, indicating a conservation of larger, more fatigue-prone motor units, which might be less recruited in children (2). The observed differences in neuromuscular fatigability, especially in girls, emphasize the need for further in-depth studies that should also address sex-specific differences in training and developmental changes.

EFFECT OF MENTAL FATIGUE ON COGNITIVE FUNCTION AND PHYSIOLOGICAL RESPONSES TO EXERCISE IN REFEREES

AHMED, H., DIXON, D., DAVISON, G.

UNIVERSITY OF SULAIMANI

INTRODUCTION: Introduction: Mental fatigue is a psychological phenomenon that is caused by prolonged and/or demanding cognitive activity. It is important to estimate factors that impair referees' performance especially in the second half of a football match. There is limited research on the potential effects of mental fatigue on both physical and cognitive performance of referees.

METHODS: Methods: Twelve (12) active football referees aged between 18-45 years (mean ± SD: age 32.3 ± 10.0 years) were recruited from Kent County Football Association (KCFA) to take part in the study. The referees were required to visit the laboratory on three separate occasions: a familiarisation (visit 1) and two main trials (control and mental fatigue, visits 2 and 3). Referees were required to perform a 90 min intermittent treadmill protocol after 30 min of a Stroop task: either incongruent (mental fatigue condition) or congruent (control condition). They were required to undertake the FIFA video clip test (decision-making) at the beginning (during warm-up: 13 min) and end of exercise (last 13 min). Exercise was an intermittent test which lasted 90 min in total. Heart rate, RPE and blood lactate measures were recorded before, during and after exercise. Referees also completed the PVT before and after the Stroop task, at half time and post-exercise, and the Brunel Mood Scale (BRUMS) before and after the pre-match PVT and after the post-match PVT.

RESULTS: Result: The mental fatigue condition caused a significant decrease in decision-making performance (correct decisions, beginning: 76.7 ± 7.2% decreased to end exercise: 64.6 ± 7.8%, $p < 0.001$) compared to no change in the control condition). The PVT performance was also significantly reduced post-Stroop test, at half time and post-exercise, but to a greater extent in the mental fatigue condition ($p < 0.05$).

CONCLUSION: In conclusion: mental fatigue had a negative impact on referees' cognitive performance during and after exercise. This may have implications for optimising referees' preparation and cognitive performance in real matches, which should be explored further.

Exchange Symposium

IS-EX02 CSSS-ECSS Exchange Symposium: Talents Identification of Youth Football Players

TALENTS IDENTIFICATION OF YOUTH FOOTBALL PLAYERS AND THEIR STRENGTH AND CONDITIONING TRAINING IN CHINA

LI, H.

CHINA INSTITUTE OF SPORT SCIENCE

The development of Football needs to start with youth training. The performance of elite youth football players represents the football level of a nation in the next decade. With the purpose of better understanding the strength and conditioning level of Chinese elite youth football players and identifying talents with science-based methods, the study selected 729 elite football players of U12-16, who registered under the Chinese Football Association (CFA). The players were tested with body posture, velocity, strength, endurance, agility, and flexibility in the training camp organized by CFA. It's found that compared with the youth elite football players at the same level and age in the countries strong in football, the velocity, strength, endurance, agility and flexibility of Chinese youth elite football players were relatively lower, which indicates that the strength and conditioning training in youth football players in China is overlooked to a certain extent. Meanwhile, using the method of Quartile, the study sets up the criteria of Chinese youth elite football players at the age of 12 to 16, which consists of 4 grades: outstanding, good, pass and fail. The players were encouraged to meet the requirements of pass and good. Moreover, the key players with great potential were analyzed specifically. The weaknesses of their physical fitness were pointed out, and the strength and conditioning training suggestions were provided for precise training.

RESEARCH ON ASSESSMENTS AND IMPROVEMENT STRATEGIES OF 1V1 OFFENSIVE AND DEFENSIVE ABILITY FOR YOUTH FOOTBALL PLAYERS

DINGMENG, R.

BEIJING SPORT UNIVERSITY

The "Chinese Football Association Youth Training Outline" highlights the significance of assessing and training youth football players' 1v1 ability. To better serve the talent identification, ability assessment, and training plan for elite young players,

the current study designed six scenario-based assessment methods to assess the players' performance during matches in 1v1 offensive and defensive situations. Based on the performance characteristics of 1v1 offensive and defensive behaviours, the research design consisted of three stages: action initiation, action selection, and action connection, including 12 evaluation criteria. Moreover, after investigating the relationships between players' athletic ability, coaches' subjective criteria, and the players' performance of 1v1 offensive and defensive skills, this study compared the advantages and disadvantages of different assessment methods. Research findings showed that: 1) scenario-based assessment methods are effective in capturing players' 1v1 offensive and defensive ability; 2) action selection is essential in 1v1 offensive and defensive ability; 3) players' speed quality and technical proficiency are key factors influencing their 1v1 offensive and defensive ability; 4) implementing targeted 1v1 training in various scenarios can significantly enhance players' individual offensive and defensive capabilities.

THE IMPORTANCE OF THE MUSCLE FIBER TYPE COMPOSITION FOR (YOUTH) FOOTBALL

LIEVENS, E.
GHENT UNIVERSITY

Muscle fiber type composition is an important performance determinant in multiple sports. Moreover, it has a large genetic component, contributing to talent for sports with specific exercise demands. In explosive, short duration sports elite athletes typically have a large share of fast-twitch fibers (type IIa and IIx), which contributes to larger power production capabilities. On the other hand, the best endurance athletes dispose of a large proportion of fatigue resistant slow-twitch fibers (type I). The optimal muscle fiber type composition in intermittent team sports is less straightforward, since these sports are characterized by mixed demands. Studies examining muscle fiber type composition in high level football players are scarce. Presumably because the current gold standard to measure muscle fiber type composition is an invasive muscle biopsy. In 2011, we validated a noninvasive technique to estimate muscle fiber type composition by measuring muscle carnosine based on proton magnetic resonance spectroscopy (1 H-MRS). Recently, this method was used on a cohort of 194 high level football players. A large heterogeneity in muscle fiber type compositions was found, in which 33% had a slow, 45% had an intermediate and 22% had a fast typology. Despite the fact that elite football games have become considerably faster over the past decades, rendering players' speed and power abilities as important performance characteristics, our data in elite Belgian football players rather shows the opposite: an underrepresentation of fast-twitch players. Moreover, no differences in muscle typology were found between positions (goalkeeper, center back, full back, midfielder, winger or forward). Next to positional differences, we prospectively monitored hamstring strain injuries in this cohort. Having a fast muscle typology was identified as a novel, and profound risk factor for hamstring strain injuries, which is possibly linked with a higher fatigue in fast typology players. In lab conditions FT individuals showed a more pronounced performance decrement during high-intensity exercise and need to recover longer compared to ST individuals. Which was recently corroborated in football games, as the decline in high-intensity running activities from first to second half was found to be more pronounced in players with a fast muscle typology. In conclusion, possessing a particular muscle typology is not required to play any football position at the national level. However, there are indications that FT players might fatigue more toward the end of the game compared to ST players, which likely makes them more prone to injury. Therefore, fast-twitch players might need a personalized training approach, to prevent overtraining, muscle injuries and possibly drop-out.

OP-AP02 Endurance performance

BOTH A 1-WEEK MODERATE-INTENSITY AND A 1-WEEK HIGH-INTENSITY INTERVAL TRAINING BLOCK IMPROVES DETERMINANTS OF ENDURANCE PERFORMANCE

ODDEN, I., SOLUM, K.S., MØLMEN, K.S., RØNNESTAD, B.R.
INLAND NORWAY UNIVERSITY OF APPLIED SCIENCES LILLEHAMMER

INTRODUCTION: High-intensity interval training (HIT) is considered effective for improving endurance performance in endurance athletes. Moreover, block periodization of HIT is well-known to provide additional performance improvements in endurance athletes (1). The effectiveness of moderate-intensity interval training (MIT) and the ideal training volume in this intensity zone have been widely discussed (2, 3). Cyclists often utilize both MIT and HIT in their annual training, yet the relative effectiveness of these two training regimes remains poorly explored. Hence, we aimed to compare the within-subject responses to a one-week MIT block characterized by longer work durations but lower effort, against a standard one-week HIT block with shorter work durations but higher effort, in cyclists.

METHODS: Twenty-two cyclists (♂, 21; ♀, 1; age, 19.2(3.6)years; maximal oxygen consumption (VO2max), 69.5(6.0)mL/min/kg) first conducted a 7-day MIT block and thereafter a 6-day HIT block. Both blocks were followed by a six-day taper, and the blocks were separated by ~2 months of usual training. The MIT block included six MIT sessions with 5-7x10-14-min work intervals aiming for 14-15 on the Borg 6-20 rating of perceived exhaustion (RPE). The HIT block included five HIT sessions all performed as 5x8.75-min series with multiple short intervals targeting 16-18RPE. The cyclists´ maximal 1-min power output (PO) during a VO2max-test (pVO2max), PO corresponding to 4 mmol/L [blood lactate]

(PO@4mmol), 15-min maximal PO (PO@15min), and VO2max were assessed before and after each training block. Potential differences in pre-test values between blocks were accounted for in the statistical analysis.

RESULTS: The total work interval duration in MIT and HIT block were 7:04 and 3:42 hours, respectively, with average RPE during work intervals being 14.5(0.3) and 17.1(0.4), which corresponded to 65.8(4.2) and 70.9(5.8)% of pVO2max, 85.5(3.6) and 90.0(2.7)% of HRmax, and 2.9(0.8) and 7.5(1.5)mmol/L [blood lactate], respectively. Both the MIT and HIT block effectively improved the cyclists´ pVO2max (2.4(4.5) and 3.7(3.2)%), PO@4mmol (4.5(4.5) and 2.1(2.7)%), PO@15min (4.9(8.7) and 2.8(5.3)%), and VO2max (1.5(3.9) and 2.4(3.8)%). The improvement gains did not differ between blocks, except for the improvement in PO@4mmol which was greater following the MIT block compared to the HIT block (p=0.05).

CONCLUSION: Both a MIT block, featuring lower exercise intensity but longer accumulated work interval durations, and a HIT-block, characterized by higher exercise intensity but shorter accumulated work interval durations, effectively enhance endurance performance determinants and PO@15min. Notably, the significantly greater PO@4mmol improvement following the MIT block compared to the HIT block indicates some work intensity-specific training adaptations.

THE INFLUENCE OF MENSTRUAL CYCLE PHASE ON SLEEP STAGES AND SLEEP QUALITY IN EUMENORRHEIC ENDURANCE TRAINED WOMEN.

TAYLOR, M., HROZANOVA, M., NORDENGEN, L., SANDBAKK, O., NOORDHOF, D.

UNIVERSITY OF TROMSØ

INTRODUCTION: Sleep is critical for physiological and psychological restoration and is widely recognized as one of the important factors for athletic recovery. There are indications that sleep may be affected by the fluctuating ovarian hormones across the natural menstrual cycle (MC). However, there is a lack of consensus in the literature due to differences in the determination and verification of MC phase, along with a focus on clinical populations rather than athletic women. Accordingly, the aim of this study was to investigate the effects of MC phase on sleep stages and markers of objective and perceived sleep quality in eumenorrheic, endurance trained women.

METHODS: Sixteen naturally menstruating, endurance-trained women (mean±standard deviation: 31±5 years; 62±7 kg, VO2max 55±5 mL·kg-1·min-1) were included. For two MCs participants used an at-home unobtrusive sleep monitor (Somnofy) and self-reported perceived sleep quality on a visual analog scale. MC phases were determined using calendar-based counting, urinary ovulation prediction testing, and serum hormone analysis of estrogen and progesterone. Only eumenorrheic cycles (i.e., cycle length ≥21 and ≤35 days, positive urinary ovulation test and mid-luteal progesterone ≥16 nmol·L-1) were included in the analysis. MC phases were defined as: early follicular- (EFP, first two nights after the start of menstruation), late follicular- (LFP, the two nights prior to a positive ovulation test), ovulatory- (OP, the night of a positive ovulation test and one night thereafter), mid-luteal- (MLP, the nights 7-8 days after a positive ovulation test), and late luteal-phase (LLP, the two nights prior to the onset of the subsequent menstruation). Data were analysed using linear mixed effect models in RStudio.

RESULTS: MC phase had a significant main effect on the distribution of light (p=0.011), slow wave (p=0.026), and rapid eye movement (REM, p=0.008) sleep. Total sleep time was (mean±SD) 7.2±0.7h in EFP and remained stable across the MC (p=0.162). Sleep stages were distributed as follows; 56±4% light, 17±4% slow wave and 27±4% REM sleep in EFP. During MLP, there was more light (+4%, p=0.008) and less slow wave (-3%, p=0.027) sleep compared to EFP. MC phase did not have a main effect on perceived sleep quality (p=0.768), sleep efficiency (p=0.115) or wake after sleep onset (p=0.214).

CONCLUSION: Endurance-trained women have more light and less deep sleep in MLP compared to EFP, despite no change in total sleep time or markers of objective or perceived sleep quality. While it is currently unclear how small changes in the distribution of sleep stages may influence an individual's recovery and wellbeing, these findings indicate that MC phase, among other factors (e.g. stress, training load, etc.), should be considered when monitoring or managing sleep in female endurance women.

THE RELATIONSHIP BETWEEN MUSCLE FUNCTIONS AND ENDURANCE RUNNING PERFORMANCE IN FOUR CLUSTERS: FROM THE CLASSIFICATION OF 120 RUNNERS BASED ON RUNNING FORMS

EIHARA, Y., KINOSHITA, M., JOTOKU, K., MAEO, S., KANEHISA, H., ISAKA, T.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Running economy plays a critical role in endurance running performance and can be enhanced by adding strength training to daily running [1]. However, the effects of strength training on endurance running performance vary among individuals [2] because the importance of muscle functions for each runner differs depending on running forms. For example, rearfoot strikers demonstrate greater activation of biceps femoris than forefoot strikers [3]. In addition, runners with a large knee range of motion (ROM) activate rectus femoris during the propulsion while runners with a small knee ROM tend to utilize energy through the stretch-shortening cycle (SSC) [4]. This study aimed to classify runners based on running forms and examine the relationships between muscle functions and endurance running performance within classified groups.

METHODS: 120 endurance runners (60 males) participated in this study. The participants were tested for muscle functions, including isometric and isokinetic (30°/s and 180°/s) knee extension/flexion torque, slow SSC ability (CMJ height), and fast SSC ability (drop jump and 3-rebound jump performances). Endurance running performance was assessed from the oxygen cost of running at 11 km/h and seasonal records. Ankle joint angle at touch-down and knee joint ROM during the stance phase were measured during running at 11 km/h. Cluster analysis was conducted based on two kinematic variables in each sex. Pearson correlation analysis was performed in each cluster to assess the relationships between muscle functions and endurance running performance.

RESULTS: The runners were divided into four clusters for each sex. In both sexes, there was a positive relationship between knee flexion torque and endurance running performance in runners who exhibited ankle dorsiflexion at touch-down (r=0.54–0.59). A positive relationship was found between isometric knee extension torque and endurance running performance in female runners who exhibited ankle plantarflexion at touch-down (r=0.60–0.83). Isometric and slow isokinetic knee extension torque was positively correlated to running economy in male runners with a large knee ROM (r=0.52–0.61), while fast isokinetic knee flexion torque and fast SSC ability relative to slow SSC ability were positively associated with endurance running performance in those with a small knee ROM (r=0.42–0.85).

CONCLUSION: The relationships between muscle functions and endurance running performance varied depending on the individual's running forms, as suggested by previous research findings [3, 4]. In addition, knee flexion strength appeared to be more critical in males, whereas the importance of knee extension strength may be greater in females for better endurance running performance. Thus, when runners and coaches select strength training, running forms as well as sex should be considered to maximize the improvement in endurance running performance.

ENDURANCE BEYOND LIMITS: EXPLORING THE INTERPLAY OF PERCEIVED FATIGUE AND PHYSIOLOGICAL RESILIENCE IN BACKYARD ULTRA-ENDURANCE RUNNERS

ARENALES ARAUZ, Y.L., AMPE, T., ROELANDS, B., DE PAUW, K.

VRIJE UNIVERSITEIT BRUSSEL, BELGIUM

INTRODUCTION: The Backyard Run is an ultra-endurance event where athletes run a 6.7 km lap every hour until the "last man is standing". This challenging event spans several days, imposing rigorous mental and physical demands. There is an increasing interest in exploring (1) the factors that drive individuals to surpass boundaries and (2) differences in performance. Evidence suggests that mental toughness and physiological resilience (PR), defined as the decoupling of heart rate and running speed, predict performance during ultra-endurance events (1, 2). Yet, the intricate interplay between perceived fatigue and PR during such extreme events remains unclear. We aim to explore the distinctions between proficient and less proficient runners in a backyard run, focusing on PR, perceived fatigue, and metabolic parameters.

METHODS: Eleven male ultra-runners (38 ± 8 years, BMI: 23.1 ± 1.05 kg/m², VO2max: 61.3 ± 4.4 ml/min/kg) were analyzed during a "Backyard Ultra" event in Belgium (April 2023). Runners were categorized into two performance levels based on the number of completed laps (i.e. <35 laps, >35 laps). Throughout the event, heart rate and running speed were monitored to quantify PR. Mental and physical fatigue, and glucose levels were evaluated every four laps. Additional fatigue-related blood markers (i.e. cortisol, C-reactive protein, creatine kinase) were examined before and after the event. Linear mixed-effects regression models were employed. To mitigate potential multicollinearity among fixed effects, we conducted Pearson correlations. A significance level of $p<0.05$ was used for all tests.

RESULTS: Models indicated a significant interaction effect ($p < 0.001$) between all perceived fatigue measures and performance levels, when predicting PR. Among less proficient runners (<35 laps), elevated PR was associated with increased mental and physical fatigue ($p=0.002$, $p=0.024$). In more proficient runners (>35 laps), the PR was not significantly associated with the increase in perceived mental and physical fatigue. The significant negative interaction ($p <0.001$) between glucose levels and event duration on PR was independent of performance levels. Post event, athletes exhibited elevated creatine kinase ($p<0.001$) and C-reactive protein levels ($p<0.001$), with a trending increase in cortisol ($p=0.055$).

CONCLUSION: Less proficient runners consistently show a more explicit link between perceived fatigue and PR during a backyard ultra-endurance run. This association is more complex for more proficient runners, although they feel mentally and physically fatigued, this does not affect their PR. Which possibly predicts their higher performance.

THE UPDATED CONCEPT OF THE POLARIZATION INDEX ENABLES THE INTEGRATION OF THREE INTENSITY ZONES IN ONE NUMBER AND IDENTIFIES POLARIZED TRAINING IN AN EXTENDED DEFINITION RANGE

STAUDNER, J., BAYER, X.1, HAUTSCH, N.1, MÖLLER, T.1, PETERSEN, P.1, TREFF, G.2

1: UNIVERSITY OF VIENNA, 2: PARACELSUS MEDICAL UNIVERSITY, SALZBURG

INTRODUCTION: The polarization index (PI) is a high-performance sports centered concept published in 2019 (Treff et al.) and currently applied in 31 peer-reviewed articles. It relates the fractions of a training intensity distribution (TID) consisting of the zones (z) 1, 2, and 3 as

PI = log10(z1/z2*z3*100) (eq. 1) and defines polarized TIDs if the result is > 2.00.

Since the publication of the PI, a variety of issues related to transforming context conditions appeared: (a) automated database entries are increasingly used, leading to previously unusual TIDs with intensity zones < 0.01; (b) TIDs are attracting increasing attention in the public health sector (Festa et al. 2023) where, due to lower total volumes and session frequencies, TIDs occur that are virtually never reported in high-performance sports as, e.g., z3 < z1 < z2, which can result in negative log10-arguments of eq.1; and (c) the general approach to quantify TIDs is more open to subjective ratings and session goal-based quantifications than before. To deal with some of these challenges, it was proposed to limit the calculation of the PI to TIDs z1>z3>z2 (Arjona et al. 2023), which would, however, limit its applicability. Here, we propose an update to adapt the PI without limiting its definition space.

METHODS: Given that z1,z2,z3 ∈ [0,1] and z1 +z2 +z3 = 1, where z1, z2 denote the measured fractions rounded to two decimals and z3 = 1-z1 - z2,

PInew =

0 if z1=0∨z3=0,

0 if z2=0∧ z3=0.01,

log10((min(z1,z3) *(max(z1,z3)-0.01))/0.01*100)*sgn(z1-z3) if z2=0∧(z1∧z3)>0.01,

log10((z1*z3)/z2*100)*sgn(z1-z3) else (eq. 2)

where sgn x:= –1 if x<0, 0 if x=0, and 1 if x>0.

RESULTS: A TID (given as z1-z2-z3) of (0.991-0.001-0.008) will be quantized to (0.99-0.00-0.01) and the respective PI results in 0, thereby indicating a non-polarized TID in contrast to 2.90 with eq. 1, indicating a polarized TID. Applying eq. 2, the PI of the TID (0.15-0.05-0.80) will result in -2.38 (non-polarized) instead of 2.38 with eq. 1.

CONCLUSION: Particularly the exclusive consideration of intensity zones with at least 1% of the total proportion avoids negative arguments in the log10 algorithm and the indication of a polarized TID if the fraction of z3 is not higher than 0.01. Furthermore, eq. 2 allows for the calculation of the PI in such "inversely polarized" TIDs while avoiding falsely positive indication of a polarized TID when z2z3>z2) with z2=0, subtracting the 0.01 fraction from the larger z1 accounts for the typical underestimation of the z3 percentages in heart rate-based quantifications. Thus, our proposal allows a broad application of the PI concept in health and performance-focused databases, regardless of the method used to quantify intensity zones. A 10-DAY (POLY)PHENOL-RICH DIET DID NOT IMPROVE RECOVERY FROM EXERCISE-INDUCED MUSCLE DAMAGE COMPARED TO A (POLY)PHENOL-RESTRICTED DIET IN RECREATIONALLY STRENGTH TRAINED MALES AND FEMALES

HANSELL, E., THORLEY, J., REYNOLDS, K.M., ŠKARABOT, J., JAMES, L.J., CLIFFORD, T.

LOUGHBOROUGH UNIVERSITY

INTRODUCTION: (Poly)phenols may mitigate exercise-induced muscle damage (EIMD), ostensibly due to their antioxidant and anti-inflammatory properties. However, such research is limited to high doses of (poly)phenols in singular foods or compounds, such as tart cherry juice or curcumin. Indeed, there is a paucity of research on whether interventions containing a range of (poly)phenolic foods can attenuate symptoms of EIMD, such as muscle function loss, and delayed onset of muscle soreness (DOMS). Providing a range of (poly)phenol-rich foods could elicit synergistic effects, enhancing the efficacy of (poly)phenol interventions, and offer an alternative to concentrated supplements. Thus, the aim of this study was to examine whether a (poly)phenol-rich diet could attenuate markers of EIMD.

METHODS: Thirty (n=18 males, n=12 females) recreationally strength trained individuals (age 23±3 y; height 1.74±0.11 m; mass 71.3±11.5 kg) were randomly assigned to a (poly)phenol unrestricted (U-POL) or (poly)phenol restricted (R-POL) diet for 10 days. The U-POL diet was further supplemented with high (poly)phenol foods (40 g/day of dark chocolate and walnuts) and the R-POL diet with low (poly)phenol foods (40 g/day of milk chocolate and peanuts). On day 8 of their diet, participants completed 200 eccentric knee extensions at 60°s-1 on an isokinetic dynamometer. Pre (PRE), post (POST), 24 h-post (24H), 48 h-post (48H), and 72 h-post-exercise (72H), maximum isometric voluntary force of the knee extensors (MIVF), DOMS (0-200mm VAS), and via femoral nerve stimulation, voluntary activation (VA), rate of twitch development within 0-50 ms (RTD.50), time to peak twitch (CT), and half relaxation time (0.5RT) were assessed. At PRE, POST and 48H, white blood cell (WBC), neutrophil (NEU), and lymphocyte (LYM) counts were measured. Mixed-model ANOVAs were used to examine for group x time-point interactions; Bonferroni adjustments were applied for post-hoc tests.

RESULTS: Energy intake, macronutrient intake, and total work completed during exercise did not differ between groups (P≥0.293). The U-POL group consumed more (poly)phenol-rich foods in total than the R-POL group (+322 g/day; P<0.001), including more fruits, vegetables, herbs and spices (+158 g/day; P<0.001), and wholegrains (+69 g/day; P=0.004). MIVF was reduced by ~31% post-exercise and remained ~12% below baseline at 72H (P<0.001). Exercise increased DOMS, which peaked at 48H (+148%; P<0.001). VA, CT, RTD.50, and 0.5RT were reduced at POST (P≤0.019), and at 24H for VA and RTD.50 (P≤0.043). NEU were elevated at POST (P<0.001), and LYM were reduced at POST and 48H (P<0.001). No significant group (P≥0.432) or interaction (P≥0.160) effects were observed for any variable.

CONCLUSION: A (poly)phenol-rich diet for 10 days did not significantly influence MIVF, DOMS, neuromuscular function, or WBC counts in the 72-h following 200 eccentric muscle contractions, possibly due to an insufficient dose and/or the inherent inter-individual variability in EIMD responses.

INCORPORATION OF N-3 PUFA INTO SKELETAL MUSCLE MEMBRANES ALTERS GLOBAL GENE EXPRESSION IN YOUNG AND OLDER ADULTS

BANIC, M., GALLAGHER, I.J., VAN DIJK, M., WITARD, O.C., DICK, J.R., GALLOWAY, S.D.R., RODRIGUEZ-SANCHEZ, N.
UNIVERSITY OF STIRLING

INTRODUCTION: The incorporation of omega-3 polyunsaturated fatty acids (n-3 PUFA) into the phospholipid membrane of human skeletal muscle cells modulates muscle protein turnover. However, differential effects of n-3 PUFA ingestion on gene expression in young and older adults are yet to be fully understood and may contribute, in part, to age-related differences in n-3 PUFA impact on skeletal muscle. We sought to determine the influence of n-3 PUFA ingestion on global gene expression profiles in skeletal muscle of young and older adults.

METHODS: Thirteen young (23±3 y, 7 female) and eleven older (67±6 y, 7 female) adults supplemented their diet, in capsule form, with 1.26g/day n-3 PUFA (720mg EPA + 540mg DHA) over 12 wk. Muscle biopsies were obtained at baseline and after 12 wk of supplementation for analysis of n-3 PUFA phospholipid membrane composition using gas chromatography, and global gene expression using microarrays. Gene category enrichment was determined using the Molecular Signatures Hallmark gene sets and data were analysed using R. Lean and fat mass was quantified via dual-energy X-ray absorptiometry, physical activity status monitored with ActiGraph GT3X+, and handgrip strength assessed using a Takei handgrip dynamometer.

RESULTS: The percent of n-3 PUFA relative to total fatty acids increased in muscle phospholipid membranes of young (+1.4 ± 0.2%) and older (+1.5 ± 0.5%) adults after 12 wk with no significant age-related differences (P>0.05). In young adults, n-3 PUFA ingestion downregulated two pathways related to bioenergetics (Ox Phos and ROS) and four pathways related to tissue regeneration (MYC targets, DNA repair, IFN-α, IFN-γ), while one pathway linked to tissue regeneration (Mitotic spindle) was upregulated. In older adults, three pathways related to tissue regeneration (Epithelial mesenchymal transition, Angiogenesis, IFN-γ) were upregulated, while one gene set related to bioenergetics (Ox Phos) was downregulated. Differential regulation of IFN-α, and IFN-γ gene sets was observed between age groups (upregulation in older adults, downregulation in young adults). Although physical activity increased from 39 ± 6% to 42 ± 6% of recorded time, there was no significant difference between age groups (P>0.05). No significant effect of n-3 PUFA ingestion on lean mass or strength was observed in young or older adults (P>0.05).

CONCLUSION: To conclude, the incorporation of n-3 PUFA into skeletal muscle membranes differentially alters gene sets involved in skeletal muscle regeneration and bioenergetics in young and older adults. These effects were unrelated to changes in physical activity status, lean mass, and strength over the 12-wk supplementation period. This study highlights the potential clinical application of n-3 PUFA supplementation in remodelling skeletal muscle across the lifespan.

THE EFFECTS OF 10 WEEKS OF SUPERVISED RESISTANCE TRAINING WITH TIME-RESTRICTED EATING OR NORMAL DIET ON BODY COMPOSITION IN OBESE MEN WITH METABOLIC SYNDROME

YAVETZ, R., LAHAV, Y., STERNFELD, R., GEPNER, Y.
TEL AVIV UNIVERSITY

INTRODUCTION: Resistance training (RT) and time-restricted eating (TRE) are established lifestyle modalities for enhancing body composition. Yet, their combined effect has yet to be determined. This study aimed to determine the effects of RT with either TRE or normal diet (ND) on fat mass (FM) and fat-free mass (FFM) in obese men with metabolic syndrome (MetS).

METHODS: In this randomized controlled trial, 32 obese men with MetS (aged 49.1±5.8y, BMI 31.0±4.0kg/m2, body fat 33.7±4.6%) were randomly assigned to TRE of 8 hours of eating and 16 hours of fasting (n=16) or ND (n=16) for ten weeks. Both groups consumed an isocaloric diet and underwent the same supervised whole-body RT three times per week. Body composition changes were assessed using dual-energy X-ray absorptiometry (DXA) scans pre- and post-intervention. A 2-way repeated measures ANOVA evaluated the within- and between-group differences and interaction.

RESULTS: After 10 weeks of intervention, body weight significantly decreased for the TRE group (-1±1.4 kg, p=0.02) and slightly increased (0.3±1.8 kg) for the ND group. Both dietary interventions decrease FM (TRE: -2.3±1.2 kg, ND: -2.2±1.7 kg, p<0.001 for both), with no significant differences between the groups. Although both groups showed a considerable improvement in FFM (TRE: 1.3±1.1 kg, p=0.001, ND: 2.5±0.9 p=0.001), the increase was more substantial in the ND group (p=0.003), indicating a differential effect of diet on muscle mass gains in combination with RT.

CONCLUSION: Both TRE and ND, along with RT, improve body composition in obese men with MetS, but ND was more effective in enhancing FFM. This suggests that meal timing and duration can influence muscle mass.

INGESTION OF A BLEND CONTAINING WHEY PLUS COLLAGEN PROTEIN INCREASES BOTH MYOFIBRILLAR AND MUSCLE CONNECTIVE PROTEIN SYNTHESIS RATES

AUSSIEKER, T., HERMANS, W.J.H., KAISER, J., HENDRIKS, F.K., HOLWERDA, A.M., SENDEN, J.M., VAN KRANENBURG, J.M.X., GOESSENS, J.P.B., SNIJDERS, T., VAN LOON, L.J.C.

MAASTRICHT UNIVERSITY

INTRODUCTION: Ingestion of whey protein has been reported to increase myofibrillar but not muscle connective protein synthesis rates both at rest as well as during recovery from exercise. It has been speculated that the inability of whey protein ingestion to increase muscle connective protein synthesis rates is attributed to an insufficient provision of glycine as a precursor for de novo collagen synthesis. Recently, we defined a whey and collagen protein blend (5:1 ratio) to improve post-prandial plasma glycine availability following protein ingestion. The present study assessed the ability of such a whey and collagen protein blend to increase both myofibrillar and muscle connective protein synthesis rates both at rest and during recovery from exercise.

METHODS: In a randomized, double-blind, parallel design, 28 young men (age: 25±5 y; BMI: 23.6±2.3 kg/m2) were randomly allocated to receive either 30 g of protein (25 g whey and 5 g collagen protein; BLEND, n=14) or a non-caloric placebo (PLA, n=14). Subjects received primed continuous intravenous infusions with L-[ring-13C6]-phenylalanine. Following a single session of unilateral leg resistance type exercise (leg press and leg extension), subjects ingested either BLEND or PLA. Blood and muscle biopsy (both legs) samples were collected in post-absorptive state, immediately after ingestion and over a subsequent 5 h recovery period to assess both myofibrillar and muscle connective protein synthesis rates. Time-dependent variables were analyzed by a two-factor repeated-measures ANOVA. Non-time-dependent variables were compared between treatment groups using an independent t-test. A statistical level of $P<0.05$ was accepted. All data are expressed as mean±SD.

RESULTS: Protein ingestion strongly increased plasma amino acid concentrations, including plasma leucine, glycine, and proline concentrations ($P<0.001$), whilst placebo ingestion showed no changes ($P>0.05$). There were no differences in post-absorptive myofibrillar and muscle connective protein synthesis rates between treatments ($P>0.05$). Post-prandial myofibrillar and muscle connective protein synthesis rates were higher in the exercised compared with the rested leg ($P<0.001$). In addition, myofibrillar protein synthesis rates were higher in BLEND compared to PLA in both the rested (0.038±0.008 and 0.031±0.006%/h, respectively; $P<0.05$) and exercised (0.052±0.011 and 0.039±0.009%/h, respectively; $P<0.01$) leg. Muscle connective protein synthesis rates were higher in BLEND compared to PLA in the rested (0.062±0.013 and 0.051±0.010%/h, respectively; $P<0.05$), but not the exercised (0.090±0.021 and 0.079±0.016%/h, respectively; $P=0.11$) leg.

CONCLUSION: Ingestion of a blend containing whey (25 g) plus collagen (5 g) protein increases both myofibrillar and muscle connective protein synthesis rates at rest and further increases myofibrillar but not muscle connective protein synthesis rates during recovery from exercise in recreationally active, young men.

PERSONALIZED HYDRATION STRATEGY IMPROVED FLUID BALANCE AND EXERCISE PERFORMANCE IN THE HEAT

WANG, H., LI, H., EARLY, K.

ZHEJIANG NORMAL UNIVERSITY

INTRODUCTION: Typically, sweat rate and sweat electrolyte losses have a large inter-individual variability and this makes specific hydration plan for a large population so difficult. However, a personalized approach to hydration can overcome this issue to meet a person's particular fluid and sodium needs. Thus, the purpose of this research was to investigate the effects of a personalized hydration strategy (PHS) on body fluid balance and high-intensity intermittent exercise performance.

METHODS: Twelve healthy, active participants completed a maximal oxygen consumption test (VO2max) and two 5-day trial arms. One arm was under normothermic condition (NOR; ~23°C) and the other arm was under hyperthermic condition (HYP; ~35°C). Each arm began with 3 days of familiarization exercise phase, which consisted of a 45min treadmill run at 50% VO2max. After the familiarization phase, participants randomly performed the main exercise trial with a either PHS and control (CON; day 4 and 5). The PHS was prescribed according to a participant's fluid and sweat sodium losses during familiarization phase. CON was selected the commercially available electrolyte beverage drinking ad-libitum. The main exercise trial consisted two phases: first phase was 45min treadmill run at 50% VO2max and second phase was high-intensity intermittent exercise (HIIT) at 80%VO2max, 5% grade for 60s followed by a fast walk at 40%VO2max, 5% grade for 30s until voluntary fatigue. Fluid replacement was only allowed in the first phase of exercise trial. PHS participants drank the solution with amount equally distributed every 10min, whereas CON participants drank ad-libitum. Participants then crossed over to the second arm with a washout period of 7 days to result in the following trials: NOR+PHS, NOR+CON, HYP+PHS, and HYP+CON. Canal temperature (Tc), heart rate, thirst perception, rating of perceived exertion (RPE), and the parameters of fluid balance (sweat and urine sodium [Na+]) were assessed.

RESULTS: In PHS trials, participants had a significantly greater fluid intake and less body mass loss compared to CON, regardless of environmental condition (all $p<0.001$). HYP+CON produced the lowest sweat Na+ concentration (56.2±9.0mmol/L) compared to other trials (all $p<0.001$). Under NOR condition, no HIIT exercise performance advantage

was found in PHS. However, under HYP condition, participants in HYP+PHS had a lower RPE (9±3 vs. 10±3, p=0.03) and Tc (37.0±0.4°C vs. 37.1±0.5°C, p=0.03) in the first phase of exercise compared to HYP+CON. HYP+PHS had the lowest thirst perception (3.6±2.4) compared to HYP+CON in the second phase (4.2±2.2, p=0.004) and HYP+PHS had a greater HIIT exercise performance (765±452s) compared to HYP+CON (548±283s, p=0.04).

CONCLUSION: PHS reinforces fluid intake and successfully optimizes hydration status and offset sweat sodium loss, regardless of environmental conditions. However, PHS may be or is more important to prevent negative physiological consequences during high-intensity exercise in the heat.

METABOLOMIC PROFILE OF SWIMMING SESSIONS PERFORMED AT DIFFERENT EXERCISE INTENSITIES IN HIGH PERFORMANCE SWIMMERS

GOVUS, A., LAWLER, N.G., MITCHELL, L.J.G., GOLDSMITH, C., KOZLOVSKAIA, M., PYNE, D.B.
LA TROBE UNIVERSITY

INTRODUCTION: Metabolic phenotyping uses mass spectrometry to comprehensively profile hundreds to thousands of metabolites (the products of metabolism) in a small blood volume (~0.02-0.10 mL). Such information can provide a detailed overview of the metabolic responses to swimming sessions performed at difference exercise intensities. This study explored the metabolic responses associated with three swimming sessions performed in the moderate, heavy, and severe exercise intensity domains in high performance male and female swimmers.

METHODS: Sixteen (9 males, 7 females, age: 16-24 years) Tier 3 swimmers performed a 12 × 25 m step test to determine their critical swimming speed. One week later, swimmers undertook three swimming sessions performed in the moderate (5 × 400 m on 6' at A1/A2 speed), heavy [3 × (8 × 100m on 1' 40 holding critical speed, 100 m recovery on 2')], and severe exercise intensity domains [3 × (1 × 35 m dive max on 2', 2 × 50 m dive max on 3', 200 m recovery on 5']. Each session was scheduled two days apart. 1.0 mL capillary whole blood samples were collected before and immediately following the cool down for each session, centrifuged and 0.1 mL of blood plasma was frozen for metabolic phenotyping using 1H-NMR and LC-MS spectrometry to give broad lipoprotein, lipidomic and amino acid coverage.

RESULTS: Preliminary random forest classification analysis of pre- vs. post-exercise time points revealed that exercise in the severe domain altered metabolites involved in membrane structure and energy metabolism (triacylglycerol's and phosphatidylethanolamine's), whereas exercise in the heavy and moderate domain mainly altered free fatty acids involved in oxidative energy metabolism and the inflammatory response (e.g., eicosatrienoic acid). Analysis of the log2fold change of post/pre-exercise values between swimming sessions distinguished different fatty acid profiles involved in cell membrane structure and the inflammatory response between sessions performed in the moderate, heavy, and severe domains, respectively. However, the metabolomic profile of the swimming sessions performed in the moderate and heavy domains could not be discriminated from each other as they showed a similar metabolic response.

CONCLUSION: Similar metabolic responses (altered fatty acid metabolism) were observed in the swimming sessions performed within the moderate and heavy domains, but changes in metabolites involved in cell membrane structure and the inflammatory response were key features of exercise performed in the severe intensity domain. Further research is needed to understand the variability and long-term metabolomic responses to routine swimming training in high performance swimmers.

BACKYARD RUNNING: A GUT MICROBIAL SHIFT AFTER AN ULTRA-ENDURANCE RUNNING EVENT

AMPE, T., ARENALES ARAUZ, Y.L., DEMUYSER, T., ROELANDS, B., DE PAUW, K.
VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: Both ultrarunning, an extreme sport pushing participants to their physiological limits, and the gut microbiota have gained enormous interest in recent years. Despite this growing interest, research on physiological responses during ultra-endurance events is limited, especially research on the relation with the gut microbiota1,2. Therefore, this study aims to fill this gap by exploring changes in the gut microbiota during a Backyard ultra-endurance running (BYR) event. Understanding these alterations is crucial for understanding their impact on energy metabolism, immune function and long-term health.

METHODS: Eight male ultrarunners (41 ± 9 years old, BMI: 23.0 ± 1.1 kg/m²), with personal BYR records ranging from 100.5 km to 677 km, were monitored before, during and after a BYR event. Gut microbiome was examined before (pre), immediately after (post) and two weeks after the event (recovery). Athletes diets were tracked using Food Frequency Questionnaires (pre and recovery) and food diaries (during). Together with the diet, other gut related metadata (e.g. medicines, surgeries,…), as well as performance data during the event (e.g. heart rate, pace, lactate,…) were collected in order to correlate and/or correct for during the gut microbiome analysis.

RESULTS: Preliminary results show differences in beta-diversity of the gut microbiome between pre, post and recovery samples. On phylum level, a shift in the Bacteroidetes/Firmicutes ratio was observed, with a decreased abundance of

Bacteroidetes post event compared to pre event in 6 out of 8 athletes. Additionally, in 6 out of 8 recovery samples, an increased abundance of Bacteroidetes compared to post and pre event was shown. Consistently, on family level, Prevotellaceae exhibited lower abundance in the post and higher abundance in the recovery samples. For Bifidobacteriaceae a higher abundance was found post event for 5 athletes. Lastly, results indicate a high variance in Lachnospiraceae abundance across the different time points.

CONCLUSION: Performing an ultra-endurance running event is associated with a temporary shift in bacterial composition in the gut and with the increased/decreased representation of some bacterial phyla and families immediately after the event and after recovery. Correcting for and/or correlating the gut microbiome data with the diet and metadata of the athletes, should confirm these results. Notwithstanding, the abundance of Prevotellaceae and Lachnospiraceae are typically associated with a higher fiber intake, which was lower during the event. Further analysis on species level, as well as metabolomic analysis should reveal further details on the effect of an ultra-endurance running event on the gut microbiome.

METABOLOMIC SIGNATURE OF SHORT-TERM LOW ENERGY AVAILABILITY

NUSSER, V., MURPHY, C., WASSERFURTH, P., KOEHLER, K.

TECHNICAL UNIVERSITY OF MUNICH

INTRODUCTION: The impact of low energy availability (LEA) on metabolic processes has been widely documented in the literature, with notable alterations observed in various metabolic, endocrine and physiological pathways, e.g., sex hormones as well as indicators of bone and iron metabolism. However, a comprehensive understanding of the metabolic perturbations associated with LEA remains elusive. Metabolomics, capable of analyzing a vast array of metabolites at once, provides a unique opportunity to uncover the potentially complex metabolic signature of LEA, which holds promise for improved detection and characterization of LEA status.

METHODS: In this study, we employed nuclear magnetic resonance-based metabolomics to quantify 250 metabolites and metabolite ratios in post-intervention blood samples obtained following short-term exposure to LEA (15 kcal/kg fat-free mass (FFM)/day) and normal EA as control (CON; 40 kcal/kg FFM/day). Blood samples utilized in our analysis were sourced from two larger crossover design studies (n=13, 85% males, aged 23.2±3.5 years), one of which involved daily aerobic exercise across both conditions, expending 15 kcal/kg FFM/day. We used generalized estimating equations to evaluate the effects of LEA on metabolite concentrations, while employing multiple logistic regression to predict LEA status based on metabolic profiles.

RESULTS: We observed significant condition effects in 120 out of 250 metabolites, independent of exercise. Notably, triglycerides (LEA vs. CON: 0.63±0.20 vs. 0.99±0.44 mmol/L, adjusted $p<0.05$), fatty acids (9.22±1.38 vs. 10.65±2.51 mmol/L, adjusted $p<0.05$), ketone bodies (0.30±0.25 vs. 0.03±0.02 mmol/L, adjusted $p<.001$) and very-low density lipoprotein (VLDL) sub-classes (adjusted $p<0.05$) exhibited significant differences. Furthermore, the stepwise inclusion of these variables into a logistic regression model demonstrated their ability in predicting LEA status (LEA ~ Acetoacetate + Total triglycerides + Ratio of saturated fatty acids to total fatty acids, AIC=18.3, $p<.001$).

CONCLUSION: Our analysis revealed significant group differences across a broad spectrum of metabolites, indicative of a transition towards increased fat utilization, ketosis, VLDL lipolysis and lipid transfer to high-density lipoprotein particles. These findings underscore the potential of metabolomics for identifying the metabolic signature of LEA, which may in turn be used to identify individuals currently exposed to LEA.

EFFECTS OF ECCENTRIC CYCLING EXERCISE TRAINING WITH NEUROMUSCULAR ELECTRICAL STIMULATION AND COMPRESSIVE GARMENT ON PHENOTYPES AND MITOCHONDRIAL METABOLISM IN T LYMPHOCYTES

PENG, S.C., LU, T.Y., LO, K.M., WANG, J.S.

CHANG GUNG UNIVERSITY

INTRODUCTION: Eccentric cycling training improves exercise performance via lower metabolic demand. Assistive devices like neuromuscular electrical stimulation (NMES) and compressive garments (CG) are reported to attenuate muscle damage following high-intensity eccentric exercise. Mitochondria in T lymphocytes dominate acquired immunity and metabolism. The current understanding of eccentric cycling exercise combined with assistive devices on mitochondrial functions in T-lymphocytes remains unclear. This study attempted to evaluate the effects of eccentric cycling exercise training combined with assistive devices on phenotypes and mitochondrial metabolism of T lymphocytes.

METHODS: Twenty sedentary healthy males were randomly assigned to either eccentric cycling with assistive devices (ECA, n=10) or eccentric cycling only (ECC, n=10). Cardiopulmonary exercise testing (CPET) was conducted to determine aerobic fitness. All subjects performed ECA or ECC at an intensity of 60% to 120% maximal workload progressively on a bicycle ergometer for 40 min/day, 5 days/week for 5 weeks. A high-resolution respirometer and flow cytometer were used for analyzing mitochondrial metabolism and phenotypes in T lymphocytes. Statistics were presented using two-way repeated measures ANOVA with Bonferroni post-hoc test.

RESULTS: The ECA (176 ± 7 vs. 190 ± 8 watts, p<0.05) and the ECC (174 ± 2 vs. 192 ± 7 watts, p<0.05) both increased work rates of CPET after training for 5 weeks. The ECA decreased the pain visual analogue scale on the first week of exercise training (ECA:2.0 ± 0.5 vs. ECC:4.0 ± 0.2, p<0.05), compared to the ECC. An elevation of the percentage of central memory T cells (CD45RO+62L+) was observed in the ECC (20.9 ± 0.9 vs. 26.3 ± 2.4 %). Moreover, the intervention enhanced mitochondrial fatty acid oxidation (FAO) of lymphocytes in both ECA (29.0 ± 2.7 vs. 37.7 ± 2.9 pmol/s/106 cells, p=0.044) and the ECC (28.4 ± 3.3 vs. 38.3 ± 2.5 pmol/s/106 cells, p=0.039), the latter also increased respiration of Complex II of electron transport chain (ETC) (17.8 ± 2.2 vs. 23.7 ± 1.6 pmol/s/106 cells, p=0.023).

CONCLUSION: The ECA predominately alleviates perceived muscle soreness during exercise training. In addition, both ECA and ECC increase mitochondrial FAO capacity, whereas only the ECC enhances ETC Complex II metabolism, and there is no significant difference between the two regimens.

OP-MH08 Resistance training in older adults

INVESTIGATING THE EFFECTS OF PEER-VOLUNTEER SUPERVISED RESISTANCE TRAINING ON PHYSICAL FUNCTION AND STRENGTH IN COMMUNITY-DWELLING OLDER ADULTS.

DOWLING, C., KING, L., FITZPATRICK, P., OHAGAN, C.

SOUTH EAST TECHNOLOGICAL UNIVERSITY CARLOW

INTRODUCTION: Resistance training (RT) improves physical function (PF) and strength in older adults. However, a dependency on health and exercise professionals may hinder older adults' accessibility to RT. Replacing health and exercise professionals with peer volunteers may increase the accessibility of RT to older adults. The aim of this study was to determine the effectiveness of peer supervised RT for improving PF and strength in older adults.

METHODS: Stage 1: Six RT trained older adults (68 ± 4 years, 50% female) completed a 4-week programme of workshops to prepare them for supervising RT sessions. The programme was designed and delivered by the lead researchers and topics included anatomy, principles of RT, RT for older adults, RT safety, exercise instruction, intensity monitoring, and an externally accredited sports first aid qualification.

Stage 2: Ninety-eight community dwelling, healthy older adults (67 ± 4 years, 86% female) were randomly assigned to Peer Supervised RT (PEER), Professionally Supervised RT (PRO), or to a non-exercise Control (CON). Training groups completed 10 weeks of RT, training twice weekly. PF was assessed using the Timed Up-and-Go (TUG) and the 30 Second Chair Stand Test (30CST). Strength was measured using Handgrip dynamometry (HG). A two-way repeated measures ANOVA determined the effects of training and supervision type on physical outcomes.

RESULTS: Drop-out rates were similar in PEER (22%) and PRO (25%). However, retention (defined as returning a completed training diary, attending > 50% of training sessions, and participating in all testing sessions) was higher in PRO (72%) than PEER (60%). Participants attended 80% of training sessions with no difference between groups. TUG improved in both PEER (8.24 ± 0.31s vs 7.00 ± 0.20s; $p < 0.001$, $\eta p2 = 0.31$) and PRO (7.70 ± 0.28s vs 6.78 ± 0.178s; $p < 0.001$, $\eta p2 = 0.26$), as did 30CST (PEER; 16.90 ± 0.85 stands vs 22.05 ± 1.00 stands; $p < 0.001$, $\eta p2 = 0.56$, PRO; 16.65 ± 0.77 stands vs 23.30 ± 0.91 stands; $p < 0.001$, $\eta p2 = 0.72$) and HG (PEER; 27.10 ± 1.89kg vs 28.84 ± 1.83kg; $p = 0.013$, $\eta p2 = 0.10$, PRO; 29.25 ± 1.713kg vs 33.28 ± 1.67kg; $p < 0.001$, $\eta p2 = 0.41$). There were no changes in any of the outcome measures in CON.

CONCLUSION: A 4-week programme of workshops was sufficient at providing voluntary peers with the skills required to effectively supervise a 10-week RT intervention for older adults. Peer supervised RT was as effective at improving PF and strength as professionally supervised RT.

THE ADAPTIVE RESPONSE DURING THE FIRST 8 WEEKS OF RESISTANCE TRAINING IN ELDERLY AND YOUNG ADULTS: A PRELIMINARY ANALYSIS

SPINELLO, G., SAMPIERI, A., GOLDIN, E., MASARIN, A., FRANCHI, M.V., CAMPA, F., CASOLO, A., PAOLI, A., MORO, T.

UNIVERSITY OF PADUA

INTRODUCTION: Aging is an inherent aspect of human life, characterized by a progressive decline in muscle mass and strength1. Older adults typically experience decreased muscle mass, alteration in muscle fiber size and composition, and impaired neuromuscular function compared to younger adults2. Physical exercise, particularly resistance training (RT), plays a primary role in counteracting age-related problems3. Understanding differences in adaptive response to RT between elderly and younger adults is crucial to optimize training outcomes for both populations. Therefore, we aimed to study changes in response to 8 weeks of RT focused on lower limbs between young adults (Y) and elderly (E).

METHODS: Fourteen young adults (23.7±3.0 years) and seven older adults (71.9±5.7 years) underwent a progressive dynamic RT program (3 times/week) for 8 weeks. Training protocol involved 3 sets of leg press, lunges, and leg extension and 3 upper body exercises (2 sets). Neither group had prior experience with RT. Participants were assessed at the beginning (T0), after 4 (T1) and 8 (T2) weeks. Isometric muscle strength was evaluated during maximal voluntary force (MVC) and submaximal trapezoidal contractions (15, 35, 50, and 70%), with concurrent recording of high-density surface EMG (HDsEMG) from vastus lateralis muscle. Dynamic muscle strength was evaluated with 1RM leg press and leg extension.

Body composition and muscle size (CSA) were assessed with DXA and ultrasonography (US), respectively. Moreover, muscle biopsies were obtained at T0 and T2.

RESULTS: Preliminary results demonstrated a significant increase in strength parameters. Specifically, isometric MVC significantly increased (p<0.001) from T0 to T1 (Y=+8.52%, E: +15.51%) and from T0 to T2 (Y= +20.49%, E= +17.78%) in both groups and from T1 to T2 in Y only (+8.22%). Similar results were observed in 1RM test. US analysis revealed a time x age interaction (p<0.001) for quadriceps CSA: in particular, Y significantly increased muscle size at all time points, whilst E increased only from T0 to T2. Consequently, the ratio between MVC and CSA was unaltered in the Y group but increased from T0 to T2 in the E group.

CONCLUSION: Our results suggest that an 8-week RT improved muscle strength parameters and CSA in both cohorts. However, it appears that the adaptive mechanism might be different: in the elderly strength gain seems more attributable to neural adaptation rather than morphological changes. This hypothesis could be further confirmed by the analysis of HDsEMG and muscle biopsies.

SYNERGISTIC RELATIONSHIP BETWEEN CHANGES IN MUSCLE MASS AND BIOELECTRICAL IMPEDANCE ANALYSIS PARAMETERS AFTER 12 WEEKS OF RT IN OLDER WOMEN

STAVINSKI, N., MAGALHÃES, J., ROSA, G., SARDINHA, L., CYRINO, E.

STATE UNIVERSITY OF LONDRINA

INTRODUCTION: Bioelectrical impedance analysis (BIA) parameters are often associated with cellular health and plausibly with muscle function. On the other hand, it is unknown whether prospective changes in muscle thickness due to resistance training (RT) are associated with changes in BIA-derived parameters. Therefore, we aimed to analyze the synergistic relationship between changes in muscle mass and BIA-derived parameters following 12 weeks of RT in older women.

METHODS: One hundred and seventeen older women (69.4 yrs ± 5.7 yrs) were allocated either to a RT group (n = 56) to be submitted to a 12-week RT full-body program or to a control group (n = 61). Both groups were evaluated at the beginning of the study and after 12 weeks using a BIA device to assess reactance (Xc, ohms), resistance (R, ohms), and phase angle (PhA, °), while a B-mode ultrasound was used to determine muscle thickness of three sites (arm flexors, and lateral and mid-thigh). The sum of the three sites was used as a surrogate for muscle thickness measurements (SUMmt). Dual-energy X-ray absorptiometry was also used to estimate total fat mass (FM). Repeated measures correlation was used to examine the synergistic relationship between BIA parameters and muscle thickness over time, while linear mixed models with a random intercept were used to determine the relationship when adjusted for age and FM.

RESULTS: After the intervention, Xc significantly increased in RT group (48.3 ± 7.8 to 52.8 ± 7.4) and reduced in control group (49.4± 8.22 to 46.7± 8.20), with a significant group*time interaction at the follow-up (P < 0.001). R increased only in RT group (555 ± 68 to 571 ± 63), while PhA increased in the RT group (4.97 ± 0.52 to 5.28± 0.50) and reduced in the control group (5.03 ± 0.48 to 4.78 ± 0.52), with a significant group*time interaction at the follow-up (P < 0.001). The SUMmt (cm) increased in RT group (18.2 ± 3.1 to 19.4 ± 3.0) and reduced in the control group (18.5 ± 2.8 to 17.9 ± 2.7), with a significant group*time interaction at the follow-up (P < 0.001). The SUMmt was associated with Xc (rrm = 0.50), R (rrm = 0.42), and PhA (rrm = 0.44) in the RT group, whereas no significant association was found between SUMmt and the BIA parameters in the control group (P ≥ 0.050). When adjusted by age and FM, a one-unit increase in the SUMmt in the RT group was associated with an increase of 0.83 ohms (CI 95%: 0.13/1.55 ohms) in Xc and 0.11° (CI 95%: 0.07/ 0.15°) in PhA, but not associated with R (P = 0.625). On the other hand, a one-unit increase in the SUMmt in the control group was associated with a reduction of -7.50 ohms (CI 95%: -12.6/-2.4 ohms) in R and 0.07° (CI 95%: 0.02/0.12°) in PhA, but it was not associated with Xc (P = 0.922).

CONCLUSION: Changes in SUMmt induced by RT can explain a significant part of the BIA parameters in older women. Our results suggest that changes in muscle thickness due to RT might have a role in cellular health.

THE EFFICACY OF 12-WEEK PROGRESSIVE HOME-BASED STRENGTH AND TAI-CHI SNACKING PROGRAMME IN OLDER ADULTS: A MIXED-METHOD RANDOMISED CONTROL TRIAL

LIANG, I.J., PERKIN, O.J., WILLIAMS, S., MCGUIGAN, P.M., THOMPSON, D., WESTERN, M.J.

UNIVERSITY OF BATH

INTRODUCTION: Preventing frailty in older age is crucial for maintaining independence, preventing falls, sustaining a good quality of life, and reducing the strain on health and social care due to population ageing. Currently, only 20% of adults aged 65 years or more meet the recommended guidelines for muscle strength and balance, with common participation barriers such as low self-efficacy, limited attendance at leisure settings, time constraints, and fear of pain or injury. This study aimed to investigate the efficacy of a home-based strength and Tai-Chi "exercise snacking" intervention as an easily accessible and engaging exercise solution for older adults.

METHODS: Following a qualitative study and a pilot trial examining 28-day versions of the exercise programme to establish feasibility and improve acceptability [1-2], a 12-week randomised controlled trial was conducted. The trial aimed to

explore the efficacy of exercise snacking in improving physical function and psychological outcomes. Pre-frail older adults (n=90) were randomly assigned to either 12 weeks of progressive twice-daily 10-minute strength and Tai-chi exercises or a waitlist control group. Physical function and self-reported psychological outcomes were assessed at baseline, 4, 8, and 12 weeks. Additionally, a subset of 26 intervention participants underwent semi-structured interviews to provide feedback on their experiences. Quantitative data were analysed using linear mixed models, while qualitative data were analysed using a deductive framework analysis.

RESULTS: Intervention participants exhibited improvements in strength and balance, as measured by the Short Physical Performance Battery, with estimated mean differences of 1.73 [95% CI 1.31/2.16; p<0.0001] at week 4, 1.36 [95% CI 0.95/1.77; p<0.0001] at week 8, and 1.42 [95% CI 1.00/1.85; p<0.0001] at week 12 compared to the control group. Qualitative findings indicated that participants found the programme accessible and beneficial, enhancing self-efficacy in physical activities for older adults.

CONCLUSION: A 12-week, home-based, 20-minute daily progressive exercise snacking programme can yield clinically meaningful improvements in physical function. This approach presents a low-cost, scalable method to increase strength and balance exercise participation among pre-frail older adults.

THE EFFECTS OF INDIVIDUALIZED FLYWHEEL INERTIAL VERSUS FREE-WEIGHT EXERCISE BASED ON MAXIMUM POWER LOAD IN OLDER ADULTS

SMAJLA, D., STERMECKI-PUKL, M., ŠARABON, N., SPUDIC, D.

UNIVERSITY OF PRIMORSKA

INTRODUCTION: Resistance training stands out as an effective tool for older adults, slowing the aging process and preventing declines in muscle performance and functional ability. As an alternative to gravity-dependent weights, flywheel inertial devices have emerged, offering the potential for subjects to generate greater force and power. This capability is crucial in mitigating the decline in muscle power output, a primary consequence of aging [1]. Numerous studies have undertaken comparisons between flywheel training and traditional weight-based training [2,3]. However, past research has often overlooked the objective equalization of intensity between flywheel and weight-based training, thereby limiting the conclusiveness and comparability of the effectiveness of both training methods. Our research aimed to assess the impact of a six-week exercise protocol (twice weekly) on the functional abilities of elderly individuals.

METHODS: The subjects were randomly divided into two groups. Both groups performed all-out squats at peak power loading conditions, where the experimental group (EG: N=16, 69,3 ± 5 years) used a flywheel inertial device and the control group (CG: N=14, 67,2 ± 13 years) exercised with a hex-bar (exercises for other muscle groups were identical). Before the six-week protocol, subjects underwent two familiarization visits and initial measurements, including determining the load where maximum power output was achieved (flywheel and hex-bar), balance assessment in tandem stance, up-and-go test, sit-to-stand test, the strength of knee flexors and extensors on the isokinetic device.

RESULTS: Analysis of variance revealed no significant effect of time or time-group interaction. Both groups demonstrated significant improvement in the sit-to-stand test (EG: 25 % vs. CG: 20,2 %, $p < 0,001$) and the up-and-go test (EG: 13,1 % vs. CG: 8,5 %, $p < 0,001$). An improvement was also detected in the test of maximal strength of the knee extensors (EG: 51.7 % vs. CG: 51.2 %, $p < 0.001$) and knee flexors (EG: 48.8 % vs. CG: 33.8 %, $p < 0.001$).

CONCLUSION: Flywheel inertia-based exercise has demonstrated itself as a viable alternative to traditional training by offering variable resistance based on the exercisers performance in the preceding repetition. While the EG showed slightly greater relative improvements, conducting more extended intervention studies is essential for drawing definitive conclusions in the future.

OP-AP12 Elite Running

BACKYARD RUNNING: PUSHING THE BOUNDARIES OF HUMAN PERFORMANCE

DE PAUW, K., JONES, A.M., AMPE, T., ARENALES ARAUZ, Y.L., ROELANDS, B.
VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: Backyard running is an extremely demanding ultra-endurance event where athletes strive to complete a 6.7 km lap every hour. As a 'last man standing' competition, the event concludes when the second-to-last participant quits, leaving the final runner to complete the ultimate lap. Remarkably, several athletes have surpassed the 100-lap mark, equivalent to an astounding 670 km. As the popularity of extreme ultra-endurance events continues to grow, understanding the physiological, psychological, and medical implications of participating in events like backyard running is paramount for safeguarding athletes' health and promoting informed training and participation strategies. Therefore, our objective is to assess the influence of backyard running on various aspects of performance, i.e. pacing, resilience, cognitive functioning and cardiovascular responses.

METHODS: Twelve male ultrarunners (38 ± 8 years old, BMI: 23.5 ± 1.6 kg/m², VO2max: 60.8 ± 4.7 ml/min/kg) participated in this study, with personal Backyards records ranging from 15 to 101 laps, covering distances between 100.5 km to 677 km. Participants were monitored during the "Backyard Ultra" event held on April 15th, 2023, in Kasterlee, Belgium. Cognitive performance was determined using a cognitive test battery COGNITION, including 8 cognitive tasks, before, during and after the event. During the event the rating of perceived exertion (RPE), lactate and heart rate (HR) were assessed. Physical performance was investigated using the total amount of completed laps and running speed per lap. Linear mixed-effects regression models were applied, and post-hoc t-tests were conducted using the Satterthwaite's method. A significance level of $p<0.050$ was employed for hypothesis testing.

RESULTS: Athletes completed 34 ± 17 laps equalling 227.8 ± 113.9 km with average speeds starting at 9.0 km/h and slowing down to 7.5 km/h at the end of the event. Based on the 5 training zones assessed for each participant after their cardiopulmonary exercise testing, participants ran 85.2% in zone 1 (i.e. recovery), 9.5% in zone 2 (i.e. long duration endurance), 0.1 % in zone 3 (i.e. extensive endurance), and 0.0% in zones 4 and 5 (i.e. intensive endurance and resistance, respectively). Physiological resilience (i.e. HR/speed) altered between athletes, with significantly lower values in the more proficient backyard runners at the end of the event ($p<0.050$). HR and lactate levels remained constant, whereas a progressive increase in RPE was noticed ($p\leq0.001$). A significantly worsened reaction times was observed for several cognitive tasks after the event ($p\leq0.050$), indicating reduced psychomotor speed.

CONCLUSION: These observations underscore the pivotal role of cognitive performance in constraining extreme ultra-endurance running. It also suggests that implementing strategies that enhance psychomotor speed could potentially have a positive effect on one's performance in such demanding endurance activities, including backyard running.

THE INFLUENCE OF 2-WEEK TRAINING OVERLOAD ON PHYSIOLOGICAL RESPONSES AND MARKERS OF TRAINING STRESS IN ENDURANCE ATHLETES

TALSNES, R.K., KVAM, N.O., STENSHEIM, J., SANDBAKK, Ø., NOORDHOF, D.
NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

INTRODUCTION: Endurance athletes are susceptible to an imbalance between training load and recovery, which can result in maladaptation, an unexplained decrement in performance and potential overtraining syndrome. In order to prevent athletes from transitioning along the continuum from being acutely fatigued towards overtraining syndrome, early detection and subsequent adjustments to the training process are imperative. Several studies have investigated the influence of training-overload protocols on various physiological responses and subjective-fatigue markers. Nevertheless, there is a need for contemporary knowledge into the comprehensive influence of training overload on physiological responses and markers of training stress commonly used in the overtraining literature. Therefore, this study aimed to investigate the influence of 2-week training overload on physiological responses and markers of training stress in endurance athletes.

METHODS: Nine trained endurance athletes (distance-runners and triathletes, n=6 males; VO2max = 66.8±4.9 mL·min-1·kg-1; n=3 females, VO2max = 56.6±6.6 mL·min-1·kg-1) completed 1-week baseline training, 2-week training overload (50-70% progressive increase in training load) and 1-week recovery (30-40% reduction in training load from baseline). Immediately after each training period, physiological responses during submaximal steady-state stages and a maximal incremental time to exhaustion (TTE) test while treadmill-running were assessed, as well as subjective fatigue measures and blood biomarkers.

RESULTS: No changes from baseline to after training overload were found for TTE and VO2max, although both increased after the recovery period (Δ31±24 sec and 80±75 mL·min-1, P<.05, respectively). Both maximal heart rate and blood lactate levels during the TTE test (-4±3 beats·min-1 and -1.5±1.7 mmol·L-1, P<.05), as well as heart rate and blood lactate levels at the same submaximal speed (-5±3 beats·min-1 and -0.4±0.4 mmol·L-1, P<.01), were reduced after training overload. However, these physiological responses were normalized to baseline-values following the recovery period. Subjective-fatigue markers (1-10) including perceived readiness (-2.3±1.3-point, P<.01), muscle soreness (-1.8±1.9-point, P=.02),

and fatigue (-2.3±1.8-point, P<.01) were impaired after training overload but normalized to baseline-values after the recovery period.

CONCLUSION: This study provides valuable insights into the comprehensive influence of training overload in endurance athletes. The present findings indicate that sports practitioners should incorporate information derived both from regular physiological tests and subjective fatigue-markers to detect maladaptive states at an early stage.

*Preliminary analyses due to ongoing data collection. Data including more participants and blood biomarkers with relevance for both overtraining syndrome and relative energy-deficiency in sports will be presented.

UPHILL AND HORIZONTAL INTERVAL RUNNING SESSIONS: EFFECTS ON PHYSIOLOGICAL AND NEUROMUSCULAR PARAMETERS

DANTAS DE LUCAS, R., MATTOS, B.K., TREMEL, A.C., LANZARINI, L.D.V., BORSZCZ, F.K., GUGLIELMO, L.G.A., TURNES, T.
FEDERAL UNIVERSITY OF SANTA CATARINA

INTRODUCTION: The physiological and neuromuscular effects of uphill running training need for more evidence, to improve knowledge and a proper prescription (Barnes et al., 2013). It is well known that running at different speeds and slopes induces changes in predominantly concentric or eccentric muscle contractions, which could influence the acute and chronic responses (Lemire et al. 2008). This study aimed to compare the acute physiological and neuromuscular parameters from two-interval running sessions performed by incline and horizontal treadmill settings.

METHODS: Twelve endurance-trained runners performed two incremental running tests until exhaustion (De Lucas et al. 2021), and two interval sessions composed of 10 repetitions of 1 min at maximal speed or incline that were obtained in the incremental tests (i.e. maximal aerobic workload), with recovery periods between repetitions of 1 min. VO2 and heart rate (HR) were continuously measured and averaged for each exercise interval, and for the entire session. Accordingly, the O2 pulse was calculated as the ratio of VO2/HR. Before and immediately after the 3rd, 6th, and 10th repetitions, the runners performed a countermovement jump (CMJ) to assess the neuromuscular performance. Paired t-test and ANOVA were used for analysis.

RESULTS: The maximal workload obtained from the incremental tests, and then used for interval sessions were 17.5 +/- 1.0 km/h and 17.0 +/- 1.7%, respectively, for horizontal and incline tests. The mean VO2 of the entire exercise intervals was lower for horizontal than incline sessions (52.5 +/- 6.5 and 54.7 +/- 6.7 ml/kg/min; ~91% VO2max, p =0.03), while HR was significantly higher for horizontal than the uphill session (163 +/- 10 and 157 +/- 9 bpm, respectively; p =0.01). In this way, the O2 pulse was greater for uphill than the horizontal session (25.2 +/- 3.8 and 23.3 +/- 3.4 ml/beat, respectively; p <0.01). In comparison to the baseline values of CMJ height obtained before the horizontal (32.5 +/- 4.3 cm) and incline sessions (32.8 +/- 4.4 cm), there was a decrement after the 3rd repetition for both sessions (31.5 +/- 4.4 and 31.6 +/- 3.8 cm, respectively). However, there was an augment after the 6th (33.0 +/- 4.5 cm), and 10th (33.2 +/- 4.3 cm) intervals only during the horizontal interval session. During the uphill session, the CMJ values after the 6th (31.9 +/- 4.2 cm) and 10th interval (32.2 +/- 4.1 cm) was similar to the baseline.

CONCLUSION: The interval sessions (10×1:1-min) performed by incline and horizontal at the maximal aerobic power can elicit different VO2 and HR responses, suggesting a greater cardiac efficiency during the uphill running. Regarding neuromuscular performance, one could observe that a more concentric running (i.e uphill) seems to induce more fatigue than horizontal (and eccentric) running during this kind of interval session.

THE EFFECTS OF MODERN FOOTWEAR TECHNOLOGY ON RUNNING ECONOMY: CAN TREADMILL TESTS PREDICT OUTDOOR RESULTS?

BELTRAMI, F., BAUMANN, G., NOLÉ, M., SPENGLER, C.M.
ETH ZURICH: EIDGENOSSISCHE TECHNISCHE HOCHSCHULE ZURICH

INTRODUCTION: Modern running shoes have revolutionized long-distance performances by decreasing the oxygen uptake (VO2) required to run at a given speed, which is termed running economy. Most studies performed to date rely on treadmill testing, but the extent to which these findings translate to outdoors running is not known. This study therefore aimed to compare running economy and perception of effort and comfort between running on a treadmill and running on an athletics track, using two different footwear, a modern running shoe combining high compliance, resilience and a longitudinal carbon plate in the midsole and a typical entry-level shoe.

METHODS: Following a familiarization trial including an incremental test, 16 well-trained male runners (weight 70 ± 6 kg, age 28 ± 5 years, peak oxygen uptake [VO2peak] 64 ± 4 ml·kg-1·min-1, peak running speed 20.0 ± 0.8 km·h-1) completed two testing visits, once on a treadmill and once on an athletics track. Each experimental visit consisted of twelve 5-min runs at submaximal speed (16 km·h-1) alternating two different footwear conditions: an entry-level running shoe (30 mm ethyl vinyl acetate [EVA] midsole thickness; weight 300 g per shoe; forefoot compliance 0.006 mm·N-1, resilience 74.5%) and a modern, carbon-plated running shoe (40 mm Polyether-block-amide [PEBA] midsole; weight 205 g per shoe; forefoot compliance 0.008 mm·N-1, resilience 85.1%). The shoe order was randomized and balanced between each of the four replicates, but kept constant between days. Gas exchange and heart rate were measured continuously

throughout the runs whereas as perception of effort and comfort were assessed at the end of each run using a 10-cm visual analogue scale. For comparisons, the last 2 min of each 5-min run were averaged across the repetitions.

RESULTS: With the modern running shoe, participants showed improved running economy on the treadmill (2.4 ± 1.1% and on the track (4.0 ± 1.2%), and lower heart rate on the treadmill (-1.3 ± 0.6%) and on the track (-2.0 ± 0.6%), compared with the entry-level shoe (all P < 0.001). Additionally, all participants showed reduced VO2 with the modern shoes whether tested on the treadmill (range -0.9 – -4.5%)) or track (range -2.0 – -6.7%). Perceived effort was lower with the modern shoes on both surfaces (P < 0.001) while perceived comfort was higher (P < 0.001). The magnitude of the differences in VO2 between shoes was smaller during treadmill than during track running (P < 0.001, Cohen dz 1.13). Differences in VO2 measured between shoes on the treadmill did not correlate with the differences measured on the track (relative differences r = 0.258, P = 0.336; absolute differences r = 0.340, P = 0.336).

CONCLUSION: Systematic testing with four replicates showed that the benefit of the modern running shoe during outdoor running could not be estimated from treadmill testing. Athletes should thus be encouraged to rely on outdoor testing or other metrics when choosing between different modern shoes.

ESTABLISHMENT OF PHASE SEPARATION METHOD USING IMU AND MEASUREMENT OF MUSCLE ACTIVITY DURING ONE RUNNING CYCLE ON A TREADMILL

KAJIWARA, W., HIROSE, K., KONDO, A., MIYAMOTO, N., UDA, S., ONODERA, K., NAKANO, H., TAKEDA, M.

DOSHISHA UNIVERSITY

INTRODUCTION: In this study, we attempted to analyze electromyograms (EMG) for each phase of a running cycle (4 phases: braking-, propulsion-, recovery-, and pre-activation phase) using motion phase detection by Inertial measurement unit (IMU).

METHODS: One male 800 m runner (34 years, 184 cm, 70 kg) was measured on a treadmill (RL2700E X 1000, Rodby, Sweden). The running speed increased gradually and reached the predetermined 25 km/h velocity after 10 seconds. An IMU (1000 Hz, DSP wireless motion sensor, Sports Sensing, Japan) was attached to the pelvis, thighs, lower leg, and feet, and the data were acquired during the running at the 25 km/h velocity for 15 cycles. IMUs data were processed for 8 s (15-23 s) after confirming that the subject had reached a constant speed of 25 km/h. To divide 4 phases of one running cycle, the posture (roll and pitch angles) of the waist, thigh, lower leg, and foot were estimated using the Extended Kalman Filter (EKF), and joint angles was calculated during running. The subject was captured with a camera (200 Hz, Basler ace, BASLER, Germany) from right beside the treadmill (90 degrees to the subject) during running, and the video data was used as a valid basis for estimating the running phase and joint angles estimated from IMUs. EMG (1000Hz, DSP wireless EMG sensor, Sports Sensing, Japan) was measured at 10 locations on the right leg: (1) gastrocnemius, (2) soleus, (3) tibialis anterior, (4) biceps femoris long head, (5) semitendinosus, (6) vastus lateralis, (7) rectus femoris, (8) tensor fasciae latae, (9) gluteus maximus, and (10) rectus abdominis.

RESULTS: The correlation coefficient (r) between the joint angle data estimated by the IMU and measured by the camera was r = 0.86 (p < 0.01) for the hip, r = 0.99 (p < 0.01) for the knee joint, and r = 0.83 (p < 0.01) for the ankle joint, showing a high correlation between them for all joints. The joint angle changes estimated from the IMU were divided into 4 phases of running based on the timing of each phase of one cycle obtained from the video data. As a result, the feature points of the joint angle at the timing of each running phase were clarified. Based on these featured angle joint points of the IMU, the 4 phases of one running cycle were divided for all 14 steps. The mean average errors for the phase separation timing between the IMU and the video were 0.003 ± 0.0024 sec for the braking-phase, 0.004 ± 0.0029 sec for the propulsion-phase, 0.003 ± 0.0031 sec for the recovery-phase, and 0.002 ± 0.0025 sec for the pre-activation-phase, and all within 2 standard deviations. The ten muscle activities measured showed phase-specific activity during 4 phases of one running cycle.

CONCLUSION: Based on the results of this study, it would be possible to divide a running cycle into 4 phases using the estimated joint angles changes measured by IMU, and to establish a method for analyzing muscle activity for each phase.

EFFECTS OF CLASSROOM-BASED ACTIVE BREAKS AND STANDING DESK ON HEALTH-RELATED FITNESS AND EXECUTIVE FUNCTIONS IN ADOLESCENTS

PRIVITERA, M., DE GIORGIO, A., CORREALE, L., LIBERALI, G., MARTINIS, L., DELLANNA, S., BERNARDES, A.G., IVANISKI-MELLO, A., PEYRÉ-TARTARUGA, L.A., MONTOMOLI, C., BUZZACHERA, C.F.

UNIVERSITY OF PAVIA, ITALY; ECAMPUS UNIVERSITY, ITALY; FEDERAL UNIVERSITY OF RIO GRANDE DO SUL, BRAZIL.

Introduction

Adolescents spend much of their daily time in schools, which are ideal settings for promoting health-related behaviours. Unfortunately, schools have often neglected such behaviours, including physical activity, due to their focus on academic achievement and economic restrictions. Decreased levels of physical activity, however, may compromise the scholarly purposes of academic achievements. A plausible solution is to promote time-efficient physical activity interventions, such as breaking up prolonged sedentary times with light-intensity physical activity and/or using standing desks. Whether such interventions affect parameters of health and fitness and executive functions, however, is still uncertain. We, therefore, investigated the single and combined effects of classroom-based active breaks and using standing desks on adolescents health-related fitness and executive functions.

Methods

Participants were 100 secondary school students (78% females, aged 15 to 17 yr). Four classes were randomly assigned into one of four groups: control (CT, n = 20), active breaks (ACT, n = 26), standing desks (STD, n = 26), and active breaks and standing desks combined (ACT+STD, n = 28). In both the ACT and ACT+STD groups, participants completed 3 × 8-min active breaks per weekday for 12 weeks, while in both the STD and ACT+STD groups participants completed 3 × 8-min using standing desks. In the ACT+STD group both interventions were alternate. Health-related fitness, i.e., muscular strength/power/endurance, aerobic endurance, flexibility, and blood pressure, and executive function, i.e., short-term working memory, visual attention, and task switching, were assessed at baseline and post-intervention. ANCOVA tests using baseline values as covariates were used, with P-value set as <0.05.

Results

The adherence to the interventions was relatively high (>80%). There were significant improvements in muscular endurance, aerobic endurance, flexibility, and systolic blood pressure (P<0.01), primarily in the ACT group. Similarly small, but non-significant trends were observed for muscular strength (P=0.06) and diastolic blood pressure (P=0.06). No between-group differences were observed for muscular power and all indicators of executive function (P>0.05).

Conclusion

Our findings suggest that classroom-based physical activity interventions appreciably impact health-related fitness, but not executive function, in secondary school students. The most noticeable benefits were observed when breaking up prolonged sedentary times with light-intensity physical activity. These results underscore the importance of incorporating physical activity breaks within classroom settings.

This research was funded by the Ministero dellIstruzione (DD 90 20/10/2022).

GAME ON, GRADES UP? INVESTIGATING THE IMPACT OF A TEACHER AND PUPIL DESIGNED ACUTE PHYSICAL ACTIVITY BREAK ON CHILDRENS COGNITION

DIXON, S., TEMPEST, G.D., HETTINGA, F., MCCULLOGH, N.

NORTHUMBRIA UNIVERSITY

Introduction

Physical Activity (PA) is beneficial for children's physical and mental health. Schools play a crucial role in children's health promotion strategies, and amidst a demanding academic curriculum, PA breaks should be optimised to promote key cognitive and psychological variables linked to academic performance. Feasibility, ease of implementation, and effectiveness from key stakeholders perspectives should also be considered. Utilising an acute approach provides insight into the immediate impact of PA break strategies, complementing long-term PA research. Therefore, the primary aim of this study was to examine the impact of an acute PA break, designed by children and teachers, on children's cognitive function.

Methods

In a prior study, we co-designed a PA break with children and teachers, which resulted in a 5-min PA break, consisting of playground games, performed outdoors with the whole class. Using a fully repeated measures design, preadolescent children (n=120, aged 5-11 years old) completed 5-min of playground games, usual practice (The Daily Mile) and a control (no PA) condition in a randomised and counterbalanced order. Rating of perceived exertion (RPE 1-10 scale) was measured following each PA condition and cognitive function (Stroop and Connections Tests) was measured pre, post (10-min) and following (45-min) each condition. A dependent t-test (RPE) and separate Condition (playground games, usual practice, control) by Time (pre, post, follow-up) repeated measures ANOVAs (response time and/or accuracy) were conducted (significance level, p=0.05).

Results

Perceived exertion was higher for the playground games (M=4.89, SD=2.83) vs. the usual practice (M=3.60, SD=2.87) condition (t(103) = -3.98, p<0.001). For the Connections Test, a main effect of Time (F(2,194) = 12.09, p<0.001), indicated improved accuracy pre to post (M=76.42, SD= 30.08, M=80.57, SD= 35.01) vs. post to follow-up (M=81.91, SD= 33.71). Whereas for the Stroop Test, a Condition by Time interaction (F(3,318) = 3.15, p=0.023), indicated no change in accuracy between conditions pre to post. However, accuracy reduced post-10min to follow-up in the playground games (M=93.75, SD=12.85) condition vs. usual practice (M=95.55, SD=10.44) and control (M=95.42, SD=10.77) conditions. No significant effects were recorded for response time (p>0.05).

Conclusions

A PA break consisting of playground games was co-designed to promote physiological and cognitive benefits. Compared to usual-practice, playground games felt more physiologically challenging, yet children's cognitive function was maintained at 10-min, but not 45-minutes later. These findings acknowledge the importance of the timing and type of cognitive assessment employed, and contribute to the development of feasible and effective, child and teacher led PA breaks, to harness cognitive benefits throughout the school day.

OPERATIONALISING PHYSICAL LITERACY: INVESTIGATING A PLAY-BASED PRACTITIONER EDUCATION PROGRAMME FROM PRACTITIONER TO CHILD IN THE UK

WING, K., DE STE CROIX, M., ROBERTS, W.M., BAKER, C.

UNIVERSITY OF GLOUCESTERSHIRE

INTRODUCTION: There is currently a growing inactive population of young people globally. It is widely recognised that practitioner education could impact children's Physical Literacy (PL) and subsequent Physical Activity (PA) throughout life [1]. Boing is a workshop-based programme that aims to help practitioners develop children's PL through active play; however, the programs impact is unknown. The aim of this study was to explore the efficacy of practitioner training and reach to children as the end user, using a novel, multi-method RE-AIM (Reach, Effectiveness, Adoption, Implementation, Maintenance) approach.

METHODS: 926 practitioners from 45 organisations were recruited. Three sequential questionnaires explored practitioner education pre, post and 6-months after training for self-reported attributes: knowledge, confidence and attitude (Likert scale). Wilcoxon signed-rank tests for non-parametric data investigated changes in attributes. Rank-biserial correlation [r] was utilised to calculate the effect size [2]. Further Bayesian statistical analysis was utilised to investigate changes between organisational groups. Practitioner interviews (n=17) captured perceived barriers and facilitators to use 1-year post-training. Finally, the child's voice was explored using Unfinished Stories: a novel drawing-based interview approach with 12 children from 3 organisations. Thematic content analysis was completed on both verbal data (practitioner and child) and visual narratives (child).

RESULTS: Quantitative: Perceived attributes towards PL was poor across the UK. Boing training elicited significant changes across all organisational groups ($p<0.001$, $r=0.94$). This was retained 6-months after training, however, significant decreases between post training and 6-months were evident ($p=<0.001$, $r=0.49$). Notably organisational groups did not differ with extreme evidence found for equal groups ($BF10 =<0.001$).

Qualitative: Five higher-order themes emerged from practitioners including organisation structure and paedology. Practitioners reported widespread adoption of Boing, however, barriers such as reduced contact time and policy led to practitioners not maintaining use over the year. Three higher-order themes emerged from children, including digital play and social interaction. Children described technology, identified family/friends and detailed sport/games with adults commonly absent. This differed from the practitioner narrative.

CONCLUSION: Current knowledge, confidence and attitude toward PL among practitioners is poor. Boing is effective at improving this; however, further support is required to promote continued use. Despite this, children have their own unique view of play that differs from their adult counterparts. The role of unsupervised and digital play must be acknowledged if the voice of the child is valued in child-centred research and policy [3] to promote PA throughout life.

EDUCATORS' PERCEPTIONS OF RISKS FOR PHYSICAL ACTIVITY RELATED INJURIES IN EARLY CHILDHOOD EDUCATION AND CARE (ECEC)

SOLLERHED, A.C.

KRISTIANSTAD UNIVERSITY

Introduction

Many parents worry that children will injure themselves in physical activity, which leads them to banning physically active play to a high degree. Educators in early childhood education and care (ECEC) also seem to worry about children getting hurt in physically active play, which can lead to restrictions on childrens ability to move in ECEC. The diminution of opportunities for physical activity contributes to several risks for ill health, for example being overweight and developing other health problems as well as affecting the development.

Aim

The aim of the study was to investigate ECEC educators' experiences, and perceptions of risks in children's physical activities and the ways these perceptions influenced the educators' decisions to offer opportunities for physical activities and movement in ECEC.

Methods

Semi structured interviews were carried out with 18 ECEC educators, 17 females and one male, working in five preschools in Sweden. The educators were either preschool teachers or day-care-assistants with 5-38 years in service in ECEC. The length and depth of the interviews varied, but they generally lasted between 30 and 90 minutes. The interviews were

digitally recorded and transcribed verbatim before analysis. The transcripts were analyzed by a combination of thematic analysis and qualitative content analysis.

Results

The analysis revealed three themes with adherent sub-themes.

1. Responsibility for the children included the sub-themes Caretaking and Empathy.

2. Fear of being accused included the sub-themes Fear of being hung out in media and Fear of being seen as unaccountable in the work team.

3. Low competence in movement included the sub-themes Low expectations on children's movement skills and Low personal movement skills.

Discussion

The educators described that they felt a great responsibility for the childrens safety towards the parents. If the children got hurt, they sometimes felt personal pain and anguish because they found it distressing when children hurt themselves. But they also feared being accused of not taking good care of the children. The fear of being exposed in the media was palpable, as was the fear of their colleagues opinions about what activities children could be allowed to do. Overall, their competence in leading physical activities with the children was perceived as low, resulting in limitations on the range of movement and what the children were allowed to do. Their own motor skills were limited, and many movements were considered too difficult to perform, both for themselves and for the children.

Conclusion

ECEC educators' concern about injuries and overprotective behavior risks hindering children from physical activity and movement, which in the long run can pose a a great risk to children's health and wellbeing, which should be taken under consideration. Finding a balance between safety and allowing children to explore and learn risk-management is essential for overall well-being.

Oral Presentations

OP-MH05 Disabilities and sport participation

ACUTE EFFECTS OF A MOTOTHERAPY SESSION ON THE EXPLOSIVE STRENGTH OF PEOPLE LIVING WITH DIFFERENT ABILITIES. PILOT STUDY.

PATANÈ, P., RE, F., STURARO, E., FEBBI, M., VANDONI, M., CARNEVALE PELLINO, V., GATTI, A., MARIN, L.
MASTER DEGREE COURSE OF MOTOR SCIENCES

INTRODUCTION: The literature shows that sports activities improve the overall well-being of the individual, inducing the body to produce endorphins. There is a significant reduction in stress levels and an overall improvement in the perception of ones body image even among people living with disabilities.

Freestyle Motocross is a sport activity, born from motocross, in which athletes perform stunts during jumps. In Italy, in 2008, the champion Vanni Odera, with a multidisciplinary team, created the "Freestyle Motocross Therapy" (FMX). An adapted version that allows people living with disabilities to get on a motorcycle with a trained rider, and ride a safe track. FMX has also been carried out with great success in hospitals, but the acute effects on participants functional capabilities have not yet been evaluated. The aim of this study was to evaluate the acute effects of an FMX session on the explosive strength of the upper limbs of a sample of people living with different abilities.

METHODS: Twelve people with different abilities (2 female), age 23±10.6, where recruited, received study information, signed an informed consent and completed the Satisfaction Profile (SAT-P) questionnaire, which investigates quality of life. Each person freely choose one of the three motocross events, held in Northern Italy between 15/05/2022 and 15/10/2022 , at the end of which perform the FMX. The posture on the bike was adapted to the abilities of each participant who could sit: on the side, on the tank with the legs crossed or on the passenger seat. To assess the explosive strength of the upper limbs, participants performed the medicine ball throw test (2 kg.) before (T0) and after (T1) the FMX. In both sessions, three throws were done and the best result, misured in meters, was considered.

RESULTS: SAT-P shows that the quality-of-life levels of the sample are homogeneous among the participants. In the medicine ball throw, 11 out of 12 participants improved the achieved distance at T1 compared to T0; the result, expressed as mean and standard deviation, (2.62±0.91; 2.10±1.07) is statistically significant (P-Value < 0.05).

CONCLUSION: Data show that, in acute, the FMX experience improved explosive strength.

Since we haven't done interventions to improve muscle strength, it's clear that results are due to a nervous system response. Moreover, caregivers reported that for a few days there were improvements in the performance of activities of daily living and mood. Although more studies are needed, it's possible to hypothesize that FMX may be a good integration of the care pathway of people living with different abilities.

THE ACUTE EFFECTS OF SITTING VOLLEYBALL PERFORMANCE ON THE SPINAL CURVATURES, RANGE OF MOTION AND MUSCULOSKELETAL PAIN IN ELITE-LEVEL PLAYERS

GAWEL, E., ZEBROWSKA, A., ZWIERZCHOWSKA, A.

AKADEMIA WYCHOWANIA FIZYCZNEGO IM. JERZEGO KUKUCZKI W KATOWICACH

INTRODUCTION: Lower limb amputation is known to significantly disturb body's biomechanics. The preliminary research conducted by the authors of the present study suggests that there is a relationship both between the impact of the impairment and the impact of sitting volleyball (SV) training on the structural and functional changes in player's body, however there is still lack of research that evaluated this issue in terms of initial playing position lateral lower limb amputation vs. no amputation. The aim of the study was to (1) identify and compare the structural (depth) and functional (ROM) state of the spinal curvatures and pelvis in the sagittal plane of able-bodied SV players and amputee SV players in terms of compensatory mechanism, (2) indicate the dominant location of the compensatory changes and the dominant model of the compensatory mechanisms in each of the analyzed groups of players, (3) identify the prevalence and location of the musculoskeletal pain and its predictors related to body's compensatory mechanisms.

METHODS: 26 elite-level SV players from 6 European countries participated in this study. They were divided into SG1 of lateral amputee SV players, SG2 of able-bodied SV players. A natural experiment method (SV game) was used in the study, followed by acute assessment of the functional changes in the spinal curvatures and theirs ROM assessed by Medi Mouse. Moreover, a Nordic Musculoskeletal Questionnaire from the last 7 days was used to assess the prevalence and location of the musculoskeletal pain.

RESULTS: Both groups were characterized by normative thoracic kyphosis, however deeper angle was observed in SG2, that simultaneously was characterized by decreased ROM both in flexion and extension. Moreover, in both groups a decreased depth of the lumbar lordosis angle and pelvis tilt (85%, 77%) were observed the most frequent, including decreased depth of theirs ROM. In SG1 statistically significant relationships were observed between years of SV training and the depth of pelvic tilt ($R=(-0.58)$, $p<0.05$), while in SG2 years of SV training correlated with the depth of thoracic kyphosis angle ($R=0.62$, $p<0.05$). Shoulders pain was reported the most frequent, that was found to correlate with years of SV training ($R=0.6$, $p<0.05$) in SG1 and with the depth of pelvic tilt ($R=(-0.69)$, $p<0.01$) in SG2. Furthermore, in both groups shoulders pain was found to correlate with ROM of the thoracic spine in extension(SG1) or lumbar spine in extension (SG2).

CONCLUSION: The impact of the lower limb amputation on the magnitude of the anteroposterior spinal curvatures seems to be suppressed by the impact of SV performance (extrinsic compensation). Pelvic tilt and lumbar spine can be indicated as the most common location of the compensatory changes. Moreover, SV training seems to induce functional adaptations in theirs ROM. Shoulders seems to be the most frequent location of the pain, that may be associated both with sitting position and functional adaptations in the musculoskeletal structures.

PERIODIC HEALTH EVALUATION IN PARA ATHLETES: A POSITION STATEMENT BASED ON EXPERT CONSENSUS

SILVA, A., PINHEIRO, L., VERHAGEN, E., OCARINO, J., FAGHER, K., AHMED, O., DALTON, K., MANN, D., WEILER, R., OKOTH, C., BLAUWET, C., LEXELL, J., KNEEPENS, H., DERMAN, W., WEBBORN, N., RESENDE, R.

UNIVERSIDADE FEDERAL DE MINAS GERAIS

INTRODUCTION: Para athletes present a broad range of sports-related injuries and illnesses, frequently encountering barriers when accessing healthcare services1. Furthermore, their diverse impairments and the specialized equipment used in competitions require individualized approaches to comprehend their overall health2. The Periodic Health Evaluation (PHE) is a valuable tool for continuously monitoring athletes' health, screening for health conditions, and identifying barriers to athlete's performance3. Additionally, the PHE assists in the surveillance of health problems by establishing baseline information for each athlete and providing crucial information in case of emergencies. This position statement aims to guide sports healthcare providers in the PHE for para athletes across key impairment categories: intellectual, musculoskeletal, neurological and vision.

METHODS: A panel of sixteen international experts, including epidemiologists, physiotherapists, optometrists, and physicians with expertise in para athlete health, convened via videoconferences to discuss the position statement's purpose, methods, and themes. They formed working groups to address underlying medical condition, cardiorespiratory, neuromusculoskeletal, nutritional status, mental and sleep health, concussion, and female para athlete health assessment considerations. The PHE's effectiveness lies in its comprehensive approach.

RESULTS: Health history review can provide insights into factors impacting para athlete health, inform physical assessments, and help healthcare providers understand each athlete's needs. During the PHE, considerations should encompass the specific requirements of the sport modality and the impairment itself. The evaluation enable early interventions tailored to the athletes health history. Moreover, the PHE serves as an opportunity to educate para athletes on preventive strategies that can be integrated into their training routines, enhancing their performance and overall health.

CONCLUSION: This position statement can potentially enhance clinical practice and improve the healthcare quality for para athletes, ultimately contributing to their overall health and well-being.

"2032 IS A DREAM FOR US": EXPLORING AMPUTEE FOOTBALL PLAYERS' UNDERSTANDING OF CLASSIFICATION IN PARA SPORT AND ITS APPLICATION TO AMPUTEE FOOTBALL

ESATBEYOGLU, F., GULTEKIN, B., KAYIRAN, H.

BOZOK UNIVERSITY

INTRODUCTION: The goal of the Para sport classification is to group athletes with a similar impairment into classes to increase participation and promote fair competition by minimizing the impact of eligible impairment on the outcome of competition. Despite its popularity, amputee football is not recognized as one of the Para sports by the International Paralympic Committee (IPC) due to it is lack of an evidence-based classification system. Therefore, the aim of this study was to explore the views of amputee football players on classification in Para sport and how it can be applied to amputee football.

METHODS: Semi-structured one-to-one dept interviews were conducted with 12 amputee football players (11 outside, 1 goalkeeper) aged 28.2 ± 5.57 years with 8.4±5.12 years amputee football sport experience. The participants' amputation levels were reported as transhumeral (n=1), knee disarticulation (n=3), transtibial (n=3), and transfemoral (n=5). Hermeneutic phenomenological analysis was used to capture the understanding of amputee football players views on Para sport classification and its application to amputee football for future direction. Transcribed interviews were analyzed inductively, followed by a deductive analysis.

RESULTS: Four themes were identified based on our analysis: (1) effect of amputation level, (2) meaning of amputation cause (acquired vs congenital), (3) lack of knowledge related to Para sport classification, and (4) its application amputee football classification.

CONCLUSION: The findings of this study suggest the need for a multidisciplinary scientific approach in order to establish an evidence-based classification system in amputee football. The international governing body of amputee football should be encouraged to initiate a fair classification system in amputee football according to the requirements by the IPC.

HIGHER PREVALENCE OF OSTEOPENIA IN NON-SPORTS ACTIVE COMPARED TO SPORTS ACTIVE WHEELCHAIR USERS

RISVANG, L.C., LILJEGREN, A.M.F.2, BAUMGART, J.K.3, VAN DIJK, J.W.4, STRØM, V.1,5, RAASTAD, T.1, JONVIK, K.L.1

1NORWEGIAN SCHOOL OF SPORT SCIENCES, 2WESTERN NORWAY UNIVERSITY OF APPLIED SCIENCE, 3NORWEGIAN UNIVERSITY OF TECHNOLOGY AND SCIENCE, 4HAN UNIVERSITY OF APPLIED SCIENCES, THE NETHERLANDS, 5SUNNAAS HOSPITAL

INTRODUCTION: Wheelchair (WC) users are at high risk of low bone mineral density (BMD) due to a lack of mechanical loading. Weight-bearing exercise can impact bone health, and thus, this study aimed to investigate the prevalence of low BMD in sports active versus non-sports active WC users and among different impairments.

METHODS: In this cross-sectional study, BMD of lumbar spine, hip, and femoral neck were measured by dual-energy x-ray densitometry. Participants were defined as sports active if they were currently active in organized sports for >1 yr. WC users answered an adapted International Physical Activity Questionnaire (IPAQ-SF) for the week before testing. Data are presented as mean±SD or mean difference [CI]. One-way ANOVA, independent t-tests, and Pearson correlation analyses were employed. Only valid scans were included; analysis n is provided where data are missing.

RESULTS: The study included 64 Norwegian WC users (35±10 yrs; 41% female; 50% sports active). Impairments were spinal cord injury (SCI; n=26), cerebral palsy (CP; n=21), spina bifida (n=7) or other (n=10). Overall, the BMD of the lumbar spine (n=62), hip (n=63), and femoral neck (n=63) was 1.10±0.22, 0.80±0.15 and 0.79±0.16 g/cm^2, respectively. The prevalence of osteopenia (Z-score<-1.0) was 45% for the lumbar spine, 69% for the hip, and 75% for the femoral neck.

Sports active had a lower prevalence of hip osteopenia than non-sports active (56% and 83%, n=32 vs. n=28; P=0.011). However, the BMD Z-scores did not significantly differ (0.4 [-0.1 – 1.0]; P=0.11). No differences were seen for lumbar spine or femoral neck BMD Z-scores. Lumbar spine BMD was weakly correlated with IPAQ-SF score (Pearson R=0.29; n=56; P=0.029). Lean body mass was moderately correlated with both lumbar spine and hip BMD (Pearson R=0.53 and R=0.43, respectively; n=60; both P<0.001), but no association was found for either current weekly strength training sessions or years of strength training experience with any of the BMD sites (all P>0.05).

Lumbar spine BMD Z-score was lower in those with congenital compared to acquired impairments (1.1 [0.4 – 1.9]; n=32 vs. n=29; P=0.004), in line with the tendency towards lower BMD Z-scores in those with CP compared to SCI (-1.2 [-2.4 – 0.0]; n=20 vs. n=24; P=0.050). However, hip BMD Z-score tended to be lower in those with acquired than congenital impairments (-0.5 [-1.1 – 0.0]; both n=31; P=0.056).

CONCLUSION: Osteopenia was highly prevalent, varying from 45% at the lumbar spine to 75% at the femoral neck. Those with congenital impairments had lower BMD at the lumbar spine but higher BMD at the hip than those with acquired impairments. Sports active had a lower prevalence of hip osteopenia than non-sports active, although no differences were seen in Z-scores. Strength training is generally recommended to improve bone health but was not associated with BMD in our population. Thus, further investigations of the effects of sports participation and strength training are highly warranted.

OP-MH14 Exercise and COVID-19 I

POST-COVID-19 SYNDROME (METABOLIC SYNDROME CONNECTION) AND EXERCISE INTERVENTION BENEFITS

KWAK, Y.S.
DONG-EUI UNIV

INTRODUCTION: Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has infected millions of people worldwide and caused a pandemic that is still ongoing. The virus can cause a disease named as COVID-19, which is composed of multi systemic manifestations with a pulmonary system predominance with often damage to numerous other cells and organs, leading to an array of symptoms. Many individuals have reported persistent symptoms and/or complications lasting beyond 4 weeks, which is now called post-COVID-19 syndrome. While the precise definition of Post-COVID may be lacking, the most common symptoms reported in many studies are fatigue and dyspnea that last for months after acute COVID-19. Other persistent symptoms such as cognitive and mental impairments, chest and joint pains, palpitations, myalgia, smell and taste dysfunctions, cough, headache, and gastrointestinal and cardiac issues were reported.

The purpose of this integrative review is to summarize and evaluate post-COVID-19 syndrome from a biological perspective and also discuss about physical exercise interventions. It is thus imperative to study post-COVID (short-term) and long-COVID (long-term) effects, specifically as local and systemic pathophysiological outcomes of other coronavirus-related diseases with the exercise interventions.

METHODS: Pubmed, CINAHL, Scopus, Web of Science and Google Scholar search engines were used to identify the definition, mechanism, pathophysiology of short and long post-COVID and to find long COVID-19 and exercise-intervention benefits.

RESULTS: Medical treatments for COVID-19 (anticoagulants, corticosteroids, anti-inflammatory drugs, oxygenation therapy and ventilation) and vaccination have improved patient outcomes. The majority of patients will recover spontaneously or after acute-phase management, but clinicians are now faced with long-term complications of COVID-19 including a large variety of symptoms, defined as "post-acute COVID-19 syndrome". Since the lungs are the most involved organs and the post-COVID prolonged and persistent effects are mainly related to the pulmonary system, it is crucial to define and predict the outcome and to determine the individuals that can progress to fibrosis and loss of function of lungs. The findings from our review indicated that there were four pathophysiological categories involved: virus-specific pathophysiological variations, oxidative stress, immunologic abnormalities, and inflammatory damage.

CONCLUSION: Although studies examining the pathophysiology of post-COVID-19 syndrome are still relatively few, there is growing evidence that this is a complex and multifactorial syndrome involving virus-specific pathophysiological variations that affect many mechanisms but specifically oxidative stress, immune function, and inflammation. Further research is needed to elucidate the pathophysiology, pathogenesis, and longer term consequences involved in post-COVID-19 syndrome. This recent research summarizes the current literature regarding the pulmonary complications in post-COVID syndrome and the management of these conditions with regular physical exercise. Multicomponent exercise-intervention program (4-5 days per weeks, 35-60% HRR, 100-250 minutes aerobic exercise) considered especially for the post-COVID syndrome patients were recommended with all forms of psychological support such as meditation and MBI. Adopting life style changes will be helpful to reduce post-COVID-19 syndromes

EXERCISE THERAPY IN SUBJECTS WITH POST-COVID-19 SYNDROME: EXPLORATORY DATA ANALYSIS OF DROPOUTS OF A TRAINING INTERVENTION STUDY

SICK, J., STEINBACHER, V., KOTNIK, D., KOENIG, F., RECKING, T., BENGSCH, D., KOENIG, D.
UNIVERSITY OF VIENNA

INTRODUCTION: Between 6.5 and 28.5% of people infected with SARS-CoV-2 experience long-lasting sequelae described as the Post-COVID-19 Syndrome (PCS). Recently, exercise has been investigated as a non-pharmacological therapy and it has shown to improve physical function, health-related quality of life and symptom severity. Nevertheless, some experts raised concerns about the implementation of exercise therapy in this population as post-exertional malaise (PEM) is a frequent symptom. This data analysis describes the characteristics of a study sample that discontinued an exercise intervention in order to identify possible predictors for dropout.

METHODS: As part of a randomized controlled trial, 47 patients with PCS were allocated to 12 weeks of endurance or concurrent training. Patients with PEM or a Post-COVID-19 Functional Status Score of ≥3 were excluded. The sample was grouped into subjects that finished the intervention (n=28) and dropouts (n=19) and subsequently analyzed via a group comparison of metric (independent t-Test or U-Test) and categorical data (chi-squared test). Furthermore, a logistic regression model with several predictors (BMI, age, days since COVID-19 infection, VO2peak, SF36 score, fatigue score and number of symptoms) as well as the odds ratios for dropout of the most prevalent symptoms were calculated.

RESULTS: Reasons for dropout were viral or bacterial infection (n=7), COVID-19 reinfection (n=5), compliance issues (n=4), worsening of symptoms (n=2) and injury (n=1). Dropouts and non-dropouts did not significantly differ in any demographic or outcome variable at baseline. A trend towards significance was found for the number of PCS symptoms reported at inclusion (non-dropouts: 4.7±2.6, dropouts: 6.4±3.2, p=0.058). No independent risk or protective factors were identified in

the logistic regression (p=0.345). Dizziness was the only symptom significantly associated with dropout (OR: 7.6, 95% CI: 1.4; 42.1, p=0.021).

CONCLUSION: Two subjects discontinued the training due to a worsening of their symptoms. Despite screening for exercise intolerance before enrollment, this could possibly be related to PEM. Otherwise, the overall high dropout-rate in this sample might be attributed to increased rates of respiratory tract infections and possible PCS-related alterations in immune function which increase susceptibility to infections. Dizziness could be a predictor for poor exercise tolerance, however further investigation and larger samples are needed.

THE EFFECT OF A BLENDED DIGITAL AND FACE-TO-FACE REHABILITATION PROGRAMME ON PHYSICAL FITNESS AND FUNCTIONAL CAPACITY IN PEOPLE WITH LONG-COVID.

SIMPSON, A., GALE, L., KILLINGBACK, C., DUKE, C., FENWICK, A., MOORE, D., WILLIAMS, A., HALEY, P., PEARSON, M., CROOKS, M.

UNIVERISTY OF HULL

INTRODUCTION: Long-Covid symptoms affect approximately 3% of the UK population (1.9 million people), highlighting the pressing need for an effective and scalable rehabilitation intervention. This study aimed to assess the efficacy of a novel blended rehabilitation programme on physical fitness and functional capacity of individuals with self-reported long-Covid.

METHODS: Participants enrolled on a 12-week rehabilitation programme, consisting of two distinct phases. The initial 6 weeks involved remote live group-based and on-demand exercise sessions, while the subsequent 6 weeks transitioned to in-person rehabilitation sessions at local council leisure centres. Throughout the programme participants received telephone consultations and engaged in educational and social activities. Physical fitness and functional capacity were measured using the 30 second sit-to-stand (STS) test and the Duke Activity Status Index (DASI) at baseline and after 6- and 12-weeks of rehabilitation.

RESULTS: 141 participants enrolled, 69% were female, mean (SD) 50 (12) years. Significant improvements were observed in physical fitness and functional capacity. Mean (SD) 30 second STS repetitions increased from 10 (6) at baseline, to 12 (6) at 6-weeks and 14 (5) at 12-weeks of rehabilitation ($P<0.001$, $\eta2= 0.173$), with 62% of participants demonstrating an improvement of more than the minimally clinically important difference (MCID) of 2 repetitions over the course of the rehabilitation programme. Similarly, DASI scores improved from 34 (15) at baseline to 39 (14) at 6-weeks and 42 (14) at 12-weeks of the programme ($P<0.001$, $\eta2= 0.268$), with 58% of individuals demonstrating improvements of more than the MCID (5 units).

CONCLUSION: A blended digital and face-to-face rehabilitation programme resulted in statistically and clinically important differences in physical fitness and functional capacity in patients with self-reported long-Covid and may provide a scalable solution to assist in widescale treatment of long-Covid.

FEASIBILITY AND EFFICACY OF AN UNSUPERVISED AEROBIC EXERCISE TRAINING PROGRAM FOR PARTICIPANTS WITH PERSISTENT SYMPTOMS >12 MONTHS AFTER SARS-COV-2 INFECTION: A RANDOMIZED CONTROLLED PILOT STUDY

WIEWELHOVE, T., EMMEL, C., SCHNEIDER, C., EIßMANN, M., BRUDER, O., SCHMIDT, B.

IST UNIVERSITY OF APPLIED SCIENCES

INTRODUCTION: The aim of the present pilot study was to assess the feasibility and general efficacy of a twelve-week individualized aerobic exercise training intervention for patients with persistent symptoms following a SARS-CoV-2 infection (long COVID syndrome).

METHODS: A total of 62 individuals with persistent symptoms, including respiratory issues, headaches, and concentration problems, 12 months post SARS-CoV-2 infection, were randomized into the intervention or control group, stratified by age and sex. Following initial assessments and detailed training consultations, the intervention group underwent a 12-week unsupervised aerobic endurance training intervention. The control group was instructed to maintain their existing activity levels at the time of the initial assessment for 12 weeks without engaging in additional systematic training. Both groups documented each training session using monitoring software. After 12 weeks, both groups underwent a final assessment. Self-reported health parameters (e.g., severity of persistent symptoms after SARS-CoV-2 infection), body composition (including muscle and fat mass), and spiroergometric and performance-related measures (e.g., VO2max and W at ventilatory thresholds 1 and 2) were recorded during the initial and final assessments. Out of the initially randomized 62 individuals, a total of 54 were included in the final analysis due to dropouts. The analysis was conducted as an intention-to-treat, per-protocol, and as-treated analysis, as well as using regression methods (difference-in-differences approach [DID]).

RESULTS: The calculated confidence intervals from the DID showed no clinically relevant differences in the changes of measured parameters between the groups. The calculated effect sizes from the DID revealed small to moderate positive effects on various self-reported health parameters favoring the endurance training intervention, but no effects on body composition and spiroergometric measures. When comparing analysis principles, fewer positive effects on various self-reported health parameters were observed in the per-protocol analysis compared to the intention-to-treat and as-treated analyses. The effects on body composition and spiroergometric measures did not differ based on the analysis principle. Training monitoring indicated low adherence.

CONCLUSION: An unsupervised endurance training program had a slight positive impact on relevant health perception parameters in individuals with persistent symptoms after SARS-CoV-2 infection. Regarding changes in physiological and

subjective health and performance markers, the intervention showed neither efficacy, likely partially attributed to low adherence, nor harm.

PERSISTENCE OF DYSPNEA, FATIGUE AND EXERCISE INTOLERANCE 2 YEARS AFTER THE ORIGINAL SARS-COV-2 INFECTION: IN THE SEARCH FOR PATHOPHYSIOLOGICAL MECHANISMS

BALDASSARRE, G., ZUCCARELLI, L., FAVARETTO, T., URSELLA, C., PALOMBA, A., SOZIO, E., TASCINI, C., GRASSI, B.
UNIVERSITY OF UDINE

INTRODUCTION: Following the acute infection with the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), a substantial percentage of patients refer persisting and often debilitating symptoms like dyspnea, fatigue and exercise intolerance. These symptoms are often grouped in a syndrome termed "Long COVID". The aim of the present study was to evaluate the persistence of Long COVID symptoms after about 2 years from the original infection, and to investigate potential pathophysiological mechanisms.

METHODS: After about two years (26±5 months, x±SD) from the original COVID-19 infection, 26 sedentary patients, males and females, were recruited for the present study. Among these patients, 12 (Long COVID; 57±6 yr) complained the persistence of symptoms related to Long COVID, whereas 14 (CTRL; 57±8 yr) did not refer these symptoms. Quality of life was assessed by the SF-36 questionnaire. Microvascular/endothelial function (increased femoral artery blood flow) during passive leg movements was evaluated by Eco-Doppler. Knee extensors maximal muscle force was assessed by isometric dynamometry. Participants performed an incremental test (INCR) and a moderate-intensity (MOD) exercise on a cycle ergometer. Pulmonary gas exchange was determined. Skeletal muscle oxidative function was evaluated in-vivo by determining the recovery kinetics of skeletal muscle O2 uptake ($\dot{V}O_2$m) by near-infrared spectroscopy and the repeated occlusions method.

RESULTS: Significantly lower scores were observed in Long COVID vs. CTRL patients in all the investigated domains by SF-36, indicating a poorer quality of life in the first group. No signs of sarcopenia were identified by an ultrasound index of muscle mass. Muscle strength was similar between the two groups. The variables evaluating microvascular/endothelial function were not different in the two groups, although below reference values. During INCR, $\dot{V}O_2$peak (23.0±4.9 vs. 26.6±6.3 mL/kg/min; p=0.12) and "ventilatory thresholds" were not significantly different in Long COVID vs. CTRL. Signs of inefficiency of pulmonary ventilation (slope of pulmonary ventilation vs. CO2 output greater than >38) and a different ventilatory pattern (greater respiratory frequency, lower tidal volume) were observed in a subgroup (n=4) of Long COVID. Both pulmonary $\dot{V}O_2$ on-kinetics during MOD and $\dot{V}O_2$m-off kinetics following MOD were not different between the two groups

CONCLUSION: More than two years after an initial infection with the SARS-CoV2 virus, some symptoms belonging to the Long COVID syndrome (i.e. dyspnea, fatigue and exercise intolerance) are still present in some patients. Nevertheless, no differences were observed between Long COVID and CTRL patients for almost all variables evaluating the pathophysiological mechanisms potentially responsible for the symptoms which were investigated. Symptoms may be attributable to other factors (i.e. psychological/neurological) which were not investigated.

LOST IN TRANSLATION: AWARENESS, UNDERSTANDING, AND INTERPRETATIONS OF ORAL HEALTH ADVICE FOR ATHLETES – A PILOT STUDY.

BURLEIGH, M., SIMPSON, A., OHANLON, R., HENRIQUEZ, F., EASTON, C.
THE UNIVERSITY OF THE WEST OF SCOTLAND

INTRODUCTION: Carbohydrate supplementation is recommended to support performance. This has implications for oral health as frequent carbohydrate consumption causes dental decay and erosion. The prevalence of dental diseases in elite athletes exceeds that of the general population and impacts on performance and quality of life. Dental disease can be prevented by improving oral hygiene and reducing carbohydrate consumption frequency. Dental healthcare professionals (DHP) should consider barriers to behaviour change when advising athletes. Other members of the athlete support network, including coaches, may also provide advice. However, prevention advice given by DHP and Coaches and its applicability to Athletes is currently unknown.

METHODS: Guidelines for preventing dental disease in elite sports settings were reviewed. An online questionnaire, consisting of multiple-choice, scenario-based, and open-box questions was constructed to assess the knowledge and attitudes of Athletes, Coaches and DHP regarding dental disease risk and prevention. The questionnaire was piloted with Athletes (N=10) and Coaches (N=11) at the Scottish Athletics Track and Field Championships and to DHP at Glasgow Dental Hospital (N=11). DHP and Coaches were asked what dental advice, if any, they provided. Athletes were asked what dental advice they had received from their Coaches or DHP. Knowledge scores were compared with chi-squared tests and open-box question responses were analysed with deductive thematic analysis.

RESULTS: Knowledge of dental disease risk in elite athletes was poor (Correct responses Athletes 46 SD 11%, Coaches 34 SD 20%, DHP 38 SD13%). 27% of DHP believed athletes were at increased risk of disease. A greater proportion of DHP felt they had a role in the provision of diet advice relating to dental disease prevention compared to Coaches (Coaches=45%, DHP=100% p=0.04). When asked about their role in disease prevention in Athletes, there was no significant difference between groups (Coaches=36%, DHP=18% p=0.06). All DHP indicated they deliver diet advice to every patient, but only 30% of Athletes stated they had received diet advice from their DHP. Thematic analysis revealed athlete oral health was an unfamiliar topic for all groups and that DHP and coaches feel athletes are responsible for their own oral health.

CONCLUSION: Athletes, coaches, and DHP are unaware of the high prevalence of dental disease in elite sports. Despite DHP stating that they delivered targeted preventative advice, the results of the thematic analysis and responses from Athletes indicate this advice is either inadequate or not delivered. Coaches did not feel confident delivering advice to prevent dental disease. Organisations with responsibility for Athlete wellbeing should raise awareness of risk factors of dental disease specific to elite sports and ensure Athletes, Coaches and DHP are aware of feasible evidence-based ways to reduce risk.

INJURY TRENDS IN SOUTH AFRICAN FEMALE RUGBY UNION PLAYERS

PAUL, L., VILJOEN, W., READHEAD, C., SEWRY, N., CANTWELL, L., JONES, B., HENDRICKS, S.

UNIVERSITY OF CAPE TOWN

INTRODUCTION: Over the past decade, womens rugby has experienced rapid growth. This increase in participation has led to an emphasis on both performance and player safety. Understanding injury trends at various participation levels, enables development of injury prevention strategies tailored to these different levels, thus improving the development pathway for young female players. Therefore, the aim of this study is to report the different match injury tends in different age groups (U16, U18, U20 and National) among female rugby union players.

METHODS: All data were collected from annual South African women's rugby provincial or international competitions for each age group in 2023. These competitions include the u16 and u18 Girls Youth Weeks, SA U20 Women's competition and WXV 2 international Women's tournament (National level). All injuries used for analysis were match time-loss injuries. Injury data were presented as counts, proportions, and injury rate. Overlap of confidence intervals were used to determine significant differences between groups.

RESULTS: The highest injury incidence occurred in the U16 age group, while the lowest injury incidence was observed at the National level (U16: 88 (95% confidence intervals (95%CI): 50-125) injuries per 1000 player hours, National: 25 (95%CI: 0-53) injuries per 1000 player hours). Tackle related injuries had the highest injury proportion, except at the National age group. U16, U20 and National age groups exhibited the highest concussion incidence (U16: 21 (95%CI: 3-39) concussions per 1000 player hours, U20: 17 (95%CI: 5-29) concussions per 1000 player hours, National: 17 (95%CI: 0-40) concussions per 1000 player hours). The tackle event was the highest contributor to concussions (64% average), except at the National age group.

CONCLUSION: When examining patterns across U16 to National female rugby union age groups, there is a decrease in injury rates as the age groups increase. This study highlights that youth players are at higher injury risk than senior players. Tackle-related injuries remain the primary contributors to injury proportions, particularly for concussions. It is vital to prioritize tackle technique coaching and conditioning for female rugby players to address these injuries

STUDDING THE RELATIONSHIP BETWEEN LIFESTYLE HABITS AND PEDBE CLOCK IN SCHOOLED CHILDREN

PLANS SALAS, E., VASILEVA, F., FONT-LLADÓ, R., HOMS-ÀVILA, J., CAZORLA, J., BARRETINA, J., ESTELLER, M., LÓPEZ-ROS, V., PRATS-PUIG, A., JÓDAR, A.

ESCOLA UNIVERSITÀRIA DE LA SALUT I LESPORT - UNIVERSITAT DE GIRONA

INTRODUCTION: The Paediatric-Buccal-Epigenetic (PedBE) clock (1) may be used to determine the environmental factors that influence the DNA methylome in children.

Lifestyle is the individual habits, behaviours and choices that define the way of living such as: physical activity (PA), sleep and nutrition. Healthy lifestyle habits are associated to a number of health-related outcomes.

Integrated Neuromuscular Training (INT) is a comprehensive approach of physical training that focuses on motor competence. However, the relationship between the INT and the epigenetic age in children has never been studied before.

Our aim was to study whether childhood lifestyle habits as well as a 3-month-INT can affect the PedBE clock.

METHODS: A total of 40 children [7.58±0.34 years; 60% girls] were enrolled in the study. Subjects were recruited from schools in Cassà de la Selva and Salt.

Data on PA, sleep and nutrition were collected for the descriptive study. Based on the WHO recommendations (2); 60 minutes of moderate or vigorous PA per day, 10 hours per day of sleep, and a score of 8 or more in the Kidmed test were used to categorize two groups: children compliant and non-compliant whit those recommendations. For the analytical study, children were randomly divided into two groups: control or intervention group. The intervention group developed an INT program as a warm-up in physical educations lessons in the schools.

Genome-wide DNA methylation analysis was conducted on saliva samples using the Illumina Methylation Epic Array v2.0. Measures of epigenetic age acceleration were calculated using the PedBE clock. Triaxial Actigraph GT3X accelerometers

(Actigraph, Pensacola, FL, USA) were used to asses PA. Sleep data was collected with self-assess questionnaire. The Kidmed test was use to collect nutritional data. CAMSA protocol were assessed to evaluate motor competence.

RESULTS: Children compliant with physical activity and sleep recommendations showed 6 and 4-month decrease, respectively in PedBE clock when compared with non-compliant (both $p<0.037$). No differences were observed for diet recommendations. Although non-statistical significance was reached, children who undergo the INT showed a 1-month decrease in PedBE, whereas the control group showed an increase of 1.18 months.

CONCLUSION: The combination of healthy lifestyle habits and the application of the INT at school, may reverse epigenetic aging in school-children. More studies are needed for a better understanding of the mechanisms behind those associations.

THE TIME COURSE OF INJURY RISK AFTER RETURN-TO-PLAY IN PROFESSIONAL FOOTBALL

ZHANG, G., BRINK, M., AUS DER FÜNTEN, K., TRÖß, T., WILLEIT, P., MEYER, T., LEMMINK, K., HECKSTEDEN, A.

SAARLAND UNIVERSITY

INTRODUCTION: Injury risk in professional football remains high in the weeks following return-to-play (RTP). However, the time course of injury risk after RTP (i.e., the hazard curve) is largely unknown. Given the economic and competitive implications of injury burden, this knowledge gap impedes on RTP decision-making and post-RTP player management. Therefore, this study aimed to characterize the hazard curve for non-contact, time-loss injuries after RTP in male professional football (soccer) and to investigate the influence of the severity of index injury and the playing position.

METHODS: Media-based injury records from the first German football league were collected over four seasons as previously published [1]. Time-to-event analysis [2] was employed for the non-contact, time-loss injury after RTP. The Kaplan-Meier survival function was used to calculate the cumulative hazard function, from which the continuous hazard function was retrieved by derivation. The severity of index injuries was categorized according to the time loss concept: minimal (1-3 days), mild (4-7 days), moderate (8-28 days), and severe (>28 days) [3]. The playing position was considered as the players main position when the subsequent injury occurred, including goalkeeper, defender, midfielder, and forward.

RESULTS: 1623 observed and 1520 censored events from 646 players were analysed. The overall shape of the hazard curve was compatible with an exponential decline of injury risk, from an approximately two-fold level shortly after RTP towards baseline, with a half-time of about four weeks. The peak of the hazard curve was slightly delayed for moderate and more clearly for severe index injuries, as compared to minimal and mild index injuries. In contrast to other playing positions, forwards encountered a rising risk of subsequent injury after RTP. The greatest plunge of injury risk was seen in goalkeepers within the first two weeks after RTP.

CONCLUSION: For the first time this study determined the trajectory of subsequent injury risk and its influencing factors in male professional football. The demonstrated approach to estimating excess injury risk after RTP is expected to support RTP decision-making in practice. Moreover, the continuous hazard curves allow for informed specification of required follow-up period in epidemiological studies and verification of the proportional hazard assumption in data analysis.

ENHANCED SOLEUS AND HIP MUSCLES STRENGTH TRAINING CAN ALTER BIOMECHANICAL RISK FACTORS FOR ANTERIOR CRUCIATE LIGAMENT INJURY IN FEMALE ATHLETES

XINRONG, Z., BING, Y., YUE, M.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Females tend to land with a higher risk of ACL injury in comparison to males [1,2]. Research suggests that strength training programs can effectively reduce the risk of ACL injuries among female athletes [3,4,5]. Current ACL injury prevention programs primarily focus on enhancing hamstring, hip, and core muscles. However, recent studies have confirmed that during landing, soleus strength aids in the posterior translation of the tibia relative to the femur [6], reducing anterior shear force on the knee and consequently lowering ACL load [7]. To our knowledge, no study has observed whether enhanced soleus can reduce the risk of ACL injury during landing tasks. Considering the fact that the magnitude of ACL strain stems from multiplanar loading conditions and hip muscles provide the most contributions to controlling frontal displacement, the present study aimed to investigate the effect of enhancing the soleus in addition to hip muscles on additive beneficial biomechanical modifications during landing in female athletes.

METHODS: Thirty-nine female athletes were randomly assigned to soleus and hip (SAH n=13), only hip (HIP n=13), and control (CON n=13) groups. SAH and HIP underwent an 8-week strength training program and performed three sessions per week. Three-dimensional hip, knee, and ankle kinematic and kinetics data were obtained while the participants performed the bilateral and unilateral drop jumps. peak isometric strength of the plantar flexor and hip abductors was measured. Two-way repeated measures analyses of variance were conducted for each dependent variable to determine the effects of 4 weeks and 8 weeks of strength training

RESULTS: SAH showed increased peak isometric torque of the soleus in comparison to HIP (P=0.045, d=1.30) and CON (P=0.029, d=1.03). Peak isometric torque of the hip abductors increased in SAH (P=0.001, d=1.88) and HIP (P=0.04, d=1.30) compared with the CON. Plantar flexion angle at initial contact increased in SAH compared with the HIP (P=0.01, d=1.28) and CON (P=0.002, d=1.25). vGRF decreased in SAH compared with HIP (P=0.043, d=1.28) and CON (P=0.032, d=0.99). Anterior knee joint load was lower in SAH compared with HIP (P=0.02, d=1.44) and CON (P=0.02, d=2.00). Knee internal rotation moment in SAH was decreased compared with HIP (P=0.02, d=1.50) and CON (P=0.01, d=1.50).

CONCLUSION: Compared to strength training targeting only the hip, combined strength training of the hip and soleus muscles can further enhance lower limb biomechanical benefits associated with reducing the risk of ACL injuries. Therefore, the soleus muscle should be included in ACL injury prevention programs.

OP-SH17 Psychology/Stress and Anxiety

UNDERSTANDING THE USE OF SUPERSTITIOUS RITUALS IN SPORTS PEOPLE

MORRIS, B., THORNTON, C., NEAVE, N., ALLEN-BAKER, G.

NORTHUMBRIA UNIVERSITY

Before kick-off, centre pass, opening tip, and the bell ring, athletes from grassroots to the international stage perform bazar actions which seemingly have nothing to do with their sport. These actions are known as Superstitious Rituals (SRs); actions which individuals believe to be powerful in controlling luck or external variables. SRs are commonplace in sporting environments, whereby the difference between success and failure can be attributed to the smallest variable. It is therefore important to understand how athletes use SRs and how they, in turn, influence the athlete. This study explored the experiences of athletes to better understand how they both view and experience SRs. 16 individual semi-structured interviews and five focus groups were conducted with 30 participants. Three themes were identified during the thematic analysis process: Identifying Superstitions vs Pre-Performance Rituals; The Lifecycle of Superstitious Rituals; and Sporting Classifications & The Influence of Competitive Prestige. The results demonstrate the physical and mental impacts that SRs and Pre-Performance Rituals (PPRs) have on athletes, and how SRs and PPRs differ in their timings and intent. Additionally, how athletes form SRs was found to influence whether they are maintained or disappear once they are perceived to no longer work for their intended purpose. Findings challenged prior SR literature and suggested that PPRs and SRs have been interchanged leading to incorrect identification and measurement across sporting demographics (i.e., professional, team, individual, novice) and occasions. Distinguishing SRs and understanding their impact acts as a foundation for future research into whether these rituals can be beneficial or detrimental to athletes. It places the groundwork for informing grassroot Sunday league coaches, up to the top 1% of athletes, to pull on some 'lucky' underwear or ditch that 'game winning' shirt number.

ANALYSIS OF EXERCISE STRESS SCALE IN COLLEGE PHYSICAL EDUCATION CURRICULUM:BASED ON EFA AND CFA

SHEN, F.J.1, CHEN, L.Q.2, LIU, Y.3, WEI, Z.1

1 MYONGJI UNIVERSITY 2 QUZHOU COLLEGE OF TECHNOLOGY 3 HEZE MEDICAL COLLEGE

Physical education is an important part of university curriculum, aiming at promoting students physical and mental health development. However, in college physical education courses, some students may experience various pressures related to physical exercise in the process of participating in physical activities.This will affect college students physical education curriculum, enthusiasm for participation and their intention to continue to participate in sports activities in the future. Therefore, it is very important to evaluate and analyze the influencing factors of sports stress in college physical education courses.The sample of this study comes from 513 students((316 male, 197 female) in several universities in Sichuan and Henan, China. In this study, SPSS 27 andAMOS 25 were used for statistical analysis, and exploratory factor analysis and confirmatory factor analysis were used to explore the sports stress scale of college students in physical education courses.The purpose is to fully understand the potential factors that affect college students exercise stress.The results of the exploratory factor analysis indicate that sports-related stress can be extracted into four factors. These factors are as follows:1. Interpersonal Relationship Stress with Physical Education Teachers: 3 observed variable. 2. Behavioral Stress from Physical Education Teachers: 3 observed variable. 3.Academic Stress: 7 observed variable. 4.Training Stress: 5 observed variable. In total, there are 18 observed variable. The overall variance explained by these factors is 83.603% The KMO value is .966. Additionally, the reliability analysis for each variable yields the following results: Interpersonal Relationship

Stress with Physical Education Teachers (α = .881),Behavioral Stress from Physical Education Teachers (α = .870), Academic Stress (α = .958),Training Stress (α = .955). The results of the confirmatory factor analysis indicate the following fit indices:RMSEA=.080,GFI=0.810,NFI=912, TLI=.922,CFI=.931. All the standardized factor loading coefficients are above .7. This study demonstrates that through exploratory factor analysis and confirmatory factor analysis, researchers can explore and validate the fundamental dimensions of sports-related stress. By considering these dimensions, researchers can propose various stress coping strategies to enhance the continuity of sports participation.

EFFECTS OF RESISTANCE EXERCISE TRAINING ON DEPRESSIVE SYMPTOMS AMONG YOUNG ADULT WOMEN WITH SUB-CLINICAL GENERALIZED ANXIETY DISORDER: PRELIMINARY RESULTS OF A RANDOMIZED CONTROLLED TRIAL

O SULLIVAN, D., RICE, J., LYONS, M., GORDON, B.R., HERRING, M.P.
UNIVERSITY OF LIMERICK

Young adult women are at risk for Generalized Anxiety Disorder (GAD) and Major Depressive Disorder (MDD), which are highly comorbid. The antidepressant effects of resistance exercise training (RET) are established; however, little is known among young adult women with at least subclinical, or analogue, Generalized Anxiety Disorder (AGAD) with or without comorbid subclinical, or analogue, Major Depressive Disorder (AMDD).

PURPOSE: This preliminary analysis of an ongoing fourteen-week randomized controlled trial quantified the comparative efficacy of low versus moderate-to-high intensity, guidelines-based RET on depressive symptoms among young adult women with AGAD with or without comorbid AMDD.

METHODS: 22 young adult women (21.7±2.6 y) with AGAD (Psychiatric Diagnostic Screening Questionnaire GAD subscale ≥6 and Penn State Worry Questionnaire ≥45) with or without AMDD (Psychiatric Diagnostic Screening Questionnaire MDD subscale ≥9) were randomized to low or moderate-to-high intensity RET. Following a two-week familiarization, participants completed eight weeks of twice-weekly, one-to-one, World Health Organization and American College of Sports Medicine guidelines-based RET with loads of approximately 20% or 75% one-repetition maximum (1RM). The 16-item, self-reported Quick Inventory of Depressive Symptomatology (QIDS) measured depressive symptoms at baseline, end of familiarization (pre-week 1), week 4, 8, and 1-month follow-up. A 2 (group) x 5 (timepoint) RM-ANOVA examined differences between low and moderate-to-high intensity RET. Hedges' d effect sizes (95%CI) quantified the magnitude of differences in change between groups across time. Cohen's d effect sizes (95%CI) quantified the magnitude of within-group change.

RESULTS: No significant group x time interaction was found for depressive symptoms ($F(4,68)=1.46$, $p=0.223$; d=0.70 [95%CI: -0.22 to 1.63]). A significant main effect for time was found ($F(4,64)=11.42$, $p<0.001$); depressive symptoms were reduced following both low (d=0.52 [95%CI: -0.48 to 1.51]) and moderate-to-high (d=1.38 [95%CI: 0.49 to 2.27]) intensity RET from baseline to week 8. Antidepressant effects persisted at the one-month follow-up for low (d=0.78 [95%CI: -0.24 to 1.79]) and moderate-to-high (d=1.79 [95%CI: 0.80 to 2.78]) intensity.

CONCLUSION: Moderate-to-high intensity RET induced stronger reductions in depressive symptoms, with a moderate-to-large magnitude effect, compared to low intensity RET. However, the difference in change between groups (d=0.70) was not significant, potentially due to the small, preliminary sample size. Both low and moderate-to-high intensity RET induced potentially clinically-meaningful, moderate and large magnitude [within-group] reductions in depressive symptoms, respectively, that persisted at one-month follow-up.

ACUTE EVALUATION STRESS AND COGNITIVE PERFORMANCE IN CHILDREN: PROTECTIVE EFFECTS OF PHYSICAL ACTIVITY

LUDYGA, S., HANKE, M., SCHWARZ, A., LEUENBERGER, R., GERBER, M.
UNIVERSITY OF BASEL

Background: Over the last decade, children at the transition to adolescence report increasing levels of school-related stress. Acute stress has detrimental effects on higher-order cognition, such as inhibitory control, which can affect performance in examinations. However, higher levels of physical activity have been associated with better inhibitory control in children. We aimed to investigate whether physical activity can reduce the impact of acute evaluation stress on this cognitive ability. Additionally, we examined cognitive control processes, such as conflict monitoring and resolution, as potential mechanisms underlying a protective effect of physical activity.

Methods: Children aged 10 to 13 years wore accelerometers over seven consecutive days and recalled their physical activity. Using a cross-over design, 109 participants showing either low (30 min/d or less) or high levels of moderate-to-vigorous physical activity (60 min/d or more) completed a stress (Trier Social Stress Test for Children) and a control condition in randomized order. Before and after the experimental conditions, a Stroop Color-Word test was administered. Event-related brain potentials elicited by this cognitive task (i.e. PSW, N200) were recorded using electroencephalography. Moreover, salivary cortisol was collected at regular intervals throughout both the stress and control conditions.

Results: In comparison to the control condition, participants showed higher salivary cortisol concentrations, $d = 0.33$, $p < 0.001$, and a pre- to posttest decrease of accuracy on incompatible trials of the Stroop Color-Word task in the stress condition, $d = 0.27$, $p = 0.005$. Path-analyses indicated that the stress-induced decrease in accuracy was more pronounced in participants with low compared to high moderate-to-vigorous physical activity, $\beta = -0.22$, $p = 0.015$. With regard to event-related brain potentials, a lower decrease of PSW amplitude was related to a lower reduction of accuracy in the stress condition, $\beta = 0.21$, $p = 0.016$, but this change was not related to moderate-to-vigorous physical activity. Both the N200 and PSW components did not mediate the association between moderate-to-vigorous physical activity and stress-related performance changes on the Stroop Color Word task.

Conclusion: Acute evaluation stress increases cortisol levels and impairs inhibitory control in children, partly due to alterations in conflict resolution. The detrimental effect on behavioral performance is less pronounced in children with low physical activity levels, but its underlying neurocognitive mechanisms remain unclear.

Invited Symposium

IS-AP01 Bridging the gap between sport science and sport practice when working with female athletes

EXPERIENCES FROM «GOLD-STANDARD» SCIENTIFIC STUDIES ON THE FEMALE ATHLETE

NOORDHOF, D.
NORWEGIAN UNIVERSITY OF SCIENCE AND TECHNOLOGY

The female ovarian hormones, estrogen and progesterone, fluctuate throughout a 21-35 cycle and result in four distinct hormonal environments i.e., menstrual cycle phases. Since, the ovarian hormones exert an effect on more than just production, there is recently great interest in studying the effect of menstrual cycle phase on training, recovery and performance. Recent methodological guidelines on how to perform studies in sport and exercise science with women as participants recommend the use of the so called "three-step method" when investigating the effect of menstrual cycle phase on training, recovery and/or performance in non-hormonal contraceptive users (1,2). The three-step method consists of calendar-based counting (i.e., reporting the first day of menses in a diary), daily urinary ovulation testing starting at day 8, and a mid-luteal venous blood sample (3). When recruiting participants for such studies, only regularly menstruating women i.e., having menstrual cycles lasting ≥ 21 and ≤ 35 days in the two months prior to recruitment, resulting in ≥9 menstrual cycles per, and not having used hormonal contraceptives in the three months prior to recruitment, can volunteer (1,2). Subsequently the three-step method is used to determine and verify the menstrual cycle phases in which participants are tested. A posteriori, data of menstrual cycles that are not considered eumenorrheic i.e., menstrual cycles <21 or >35 days, anovulatory cycles (no positive urinary ovulation test before the next menses), and/or a mid-luteal (7-9 days after a positive urinary ovulation test) progesterone level <16 nmol•L-1, need to be excluded from analysis (1). As these disturbed menstrual cycles do not show the expected hormonal fluctuations, failure to exclude these cycles could mask potential changes in training, recovery and/or performance over the menstrual cycle. Finally, the exercise tests performed should be repeated over two menstrual cycles for the study to be classified as following "gold standard methodological control" (2). This presentation will highlight the benefits of using such a demanding and rigorous approach and experiences obtained when performing studies following these guidelines. Consequently, this presentation will be relevant for all researchers and sport practitioners considering starting projects in which they will investigate the effect of menstrual cycle phase on training, recovery and/or performance.

EXPERIENCES FROM WORKING WITH FEMALE ATHLETES IN AN APPLIED SETTING

BRUINVERLS, G.
UNIVERSITY COLLEGE LONDON

The popularity and interest in female sport has grown exponentially over the last few years. With this, the professionalism of female athletes and associated sporting environments has increased. Female athletes are pushing boundaries and breaking barriers all the time, however best practice for optimal training and support is still relatively in its infancy. The increasing evidence base highlighting the self-perceived impact of the menstrual cycle on exercise performance emphasizes the need for menstrual health screening and longitudinal tracking. However, with limited and potentially challenging guidelines, many practitioners are unsure how a proactive female athlete health monitoring approach can be implemented without 'opening a can of worms'. Little longitudinal research has been conducted in applied settings, and the application of research pertaining to female health from lab-based studies can be challenging. Typically, only a couple of hormonal time points are studied, which do not reflect the known day-to-day hormonal changes through a menstrual cycle, the implications of menstrual dysfunction, or the effects of hormonal contraception use. Given that athletes need to be able to perform on any day of their cycle this must be considered in future research. However, gold standard testing methodologies are extremely challenging to implement in applied settings, but this must not deter, and ideally research can be conducted alongside tracking. The effects that hormonal changes can have on other physiological systems and homeostatic processes are well established. Therefore, collecting and tracking female health data can provide useful contextual understanding, while also indicating any potential need for medical input. As women's sport is becoming more professional with more data analysis and given the self-reported data on the potential performance detriments that the menstrual cycle can have, tracking female health markers is an important consideration. Opportunistic 'real world' research should also be considered as this could provide a good way to bridge the overt gap between research and prac-

tice. This presentation will discuss an approach to tracking and monitoring female athletes in an applied setting, discussing how 'on the ground' monitoring can be used as a tool for practitioners and how research can be conducted in conjunction.

FEMALE ATHLETE RESEARCH – COMBINING SCIENCE AND PRACTICE

MIKKONEN, R.
UNIVERSITY OF JYVÄSKYLÄ

The female athlete population includes several unique hormonal profiles (1). Some athletes are naturally menstruating, others use combined or progestin-only hormonal contraceptives, still others have menstrual disturbances ranging from sub-clinical to clinical and which may or may not be caused by low energy availability or the multistressor environment of elite sport. Where the three-step or two-step methods for identifying menstrual cycle phases or characterizing the hormonal profiles of naturally menstruating females are important for research striving to identify the influence of sex hormone concentrations and ratios on specific mechanisms or characteristics of sports performance (2,3), it is important to recognize that these methods are not appropriate for females that are not naturally menstruating. Furthermore, these laboratory methods are not easily applied to practice and are not necessarily feasible. As a universal blueprint for training according to a natural menstrual cycle phase does not exist, the need for menstrual cycle tracking for purposes beyond menstrual (and thereby physical) health are questionable. Nevertheless, monitoring the menstrual cycle (including ovulation) and hormonal contraceptive cycles and identification of patterns in symptoms or performance that may be related to changes in hormonal concentrations may be useful for athletes, coaches, and support staff like physicians as well as researchers. In practice, menstrual and hormonal contraceptive cycle monitoring are helpful for avoiding/identifying menstrual dysfunction and decreased health and performance that are often linked to low energy availability and relative energy deficiency in sport (4). In addition, menstrual and hormonal contraceptive cycle monitoring may allow us to modify approaches to training and/or nutrition if consistent negative patterns in subjective feelings around training or within performance emerge. Communication and collaboration are needed between science and practice to better inform research and practice. In addition, communication and collaboration with clinicians regarding ´the relationship between menstrual health and health and performance is important to best serve our female athletes and improve their (and clinician) body literacy. This presentation will highlight the variety in hormonal profiles that may be observed in the female athlete population and will present practical reasons for cycle tracking and reporting of / considering hormonal profiles in both research and practice including considerations for female athletes without natural/eumenorrheic cycles.

IS-PN02 To the Moon and beyond: the physiological consequences of hypo-gravity and muscle disuse, and possible exercise countermeasures

METABOLIC AND MECHANICAL ASPECTS OF HUMAN LOCOMOTION IN HYPO-GRAVITY

PAVEI, G.
UNIVERSITÀ DEGLI STUDI DI MILANO

Human locomotion evolved and has been tuned over the year to cope with Earth gravity. This evolution ended up with walking as the preferred gait for everyday activities; whereas, when more speed is needed, running is the gait of choice. When the first astronauts landed on the Moon, they faced for the first time a lower gravity (almost 1/6 of Earth) and they adopted also (and mostly) other two gaits: skipping (the gallop for bipedal) and hopping (the gait of kangaroos). In the beginning it was thought that this shift was driven by mechanical and balance constrains, however we showed that the metabolic energy required to perform those bouncing gaits was greatly reduced in hypo-gravity, much more than in walking and running (Pavei et al. 2015). This decreased metabolic demand was parallel to a decreased mechanical work performed by the muscle-tendon system while locomoting in hypo-gravity, where not only a decreased in potential energy but also a reduced work to swing the limbs occurred. The reduced gravity decreased the locomotion efficiency, thus from a whole-body perspective it seems that the spring that usually helps muscles in the bouncing gaits was less compressed and hence less able to store and release elastic energy. This is probably given by the evolution that tuned the muscle-skeletal unit to the 1g level and it is not as effective in low gravity conditions. In this respect, the lowered metabolic demand could be even lowered whether the spring could be adjusted to the new hypo-gravity level, and this is likely to be obtained with external aids, such as passive (or active) tools. From bed-rest studies, a decrease in maximal aerobic power is reported. However, the impact of this decrease on exercise with low mechanical (and metabolic) demand, e.g. locomotion, has not well addressed yet, and those few studies reported no differences in metabolic power. Hence, we could say that locomotion could still be feasible from a cardio-metabolic point of view. On the other hand, in order to locomote muscles have to generate the needed amount of force and work, which should be coupled by tendons activity. Muscles and tendons are known to incur a great impairment post bed-rest or microgravity permanence, the muscle-tendon sys-

tem could possibly be able to maintain a walking gait, but maybe could not a bouncing gait. Another problem regards the posture and balance necessary to locomote, both seem to be impaired after a permanence in microgravity, making potentially difficult an independent locomotion. Unfortunately, there are no studies that can answer now "could astronauts move after a one-way flight to Mars?". We think that if astronauts will not follow an intensive program of countermeasures aims to use their limbs once out of the shuttle, it would be unlike that the lower metabolic demand of locomotion could help!

THE IMPACT OF VARIABLE GRAVITATION ON MUSCLE–TENDON INTERACTION AND FUNCTION

ALBRACHT, K.
GERMAN SPORT UNIVERSITY

Since Yuri Gagarin's pioneering flight in 1961, numerous missions of varying length and on a range of platforms have explored space and its effects on the human body. To maximize the benefits of future Mars and moon missions, extravehicular activities in low-gravity environments will be essential during human exploration. In sustained missions (Artemis 2), crewmembers are required to move from a defective rover to a safe location over distances of up to 12 km. A simple fall due to muscle weakness or lack of locomotor control could result in injuries or spacesuit damage that could be life-threatening. Ultrasonic visualization of muscle fascicle and tendon (SEE) behavior during locomotion has demonstrated the importance of the storage and release of elastic energy by the Achilles tendon in running and walking, and that the plantar flexor muscles modulate their behavior depending on gait type, speed, and external loading. Despite the relevance of this topic to both space travel and rehabilitation, only a few studies have examined the behavior of muscles and tendons in simulated or real hypergravity. The shorter peak SEE length observed during running in simulated 0.7 g may be the result of lower muscular forces acting on the SEE (Richter et al., 2021a). The longer fascicles observed during running in simulated (0.7 g) hypogravity may result in an increased strain on the z-disks, which in turn may be beneficial for muscle mass preservation. Decreasing g-level from 1 g to simulated Martian and lunar gravity resulted in hypogravity-induced alterations in SEE length, and contractile behavior that persisted between simulated running on the moon and Mars (Richter et al., 2021b). This should be taken into account when evaluating exercise prescriptions and the transferability of locomotion practiced in lunar gravity to Martian gravity. Monti et al. (2021) assessed fascicle behavior during the locomotor-like task—drop jump—during a parabolic flight. Upon landing, gastrocnemius medialis fascicles showed lengthening in all gravity levels below and above 1 g and quasi-isometric fascicle behavior in 1 g. Such behavior was potentially due to the lower level of muscle pre-activation (Waldvogel et al., 2021), implying a modulation of the muscle's mode of operation toward a damping function. Thus, existing studies have demonstrated that the consequences of locomotion in hypogravity are not limited to a mere reduction in mechanical loading but also to an altered contractile behavior, which could affect the muscle's work capacity upon return to daily activities in a 1 g environment and may require specific attention for adequate countermeasures and during the rehabilitation phase.

"I HOPE MY LEG DON'T BREAK, WALKING ON THE MOON" - NEUROMUSCULAR ADAPTATIONS TO DISUSE AND SPACE FLIGHT, AND THE ROLE OF EXERCISE COUNTERMEASURES

FRANCHI, M.
UNIVERSITY OF PADOVA

It is likely that space explorations will become more common very soon, considering how much effort is being put in by national space agencies and private companies. Man on the Moon part II or space hotels, like the "Voyager Station" idea don't seem to be just a dream anymore. However, one "dark side of the Moon" is that astronauts experience a dramatic loss of muscle mass following exposure to hypo-gravity and muscle disuse. This is accompanied by even bigger decrease in muscle strength and power, development of insulin resistance and detrimental metabolic and mitochondrial dysfunctions. Lower limbs muscles, and especially the anti-gravity muscles (such as the plantar flexors and the knee extensors), undergo significant wasting (~20% of fibre atrophy after 6 months of space flight for the triceps surae) (Rittweger 2018), despite the astronauts perform daily intense physical exercise that instead, on earth, would lead to muscle hypertrophic responses. Thus, even if muscle atrophy and weakness have been object of research since the 1990s, we still do not fully grasp the mechanisms regulating this dramatic muscle wasting and the strategies that are in place to counteract such atrophic process (in flight or post flight) are still not enough. Of course, the small sample size of astronauts involved in these studies, the different durations of each mission, the type of adherence of exercise programs in flight, have makes things a bit more complicated (Narici & de Boer 2011). Nevertheless, studies employing simulated micro/hypo-gravity on earth through the means of bed rest or limb suspension/casting models have provided useful data on muscle disuse and unloading not only important for space flight missions, but also of extreme interest for bed-ridden patients in hospital settings. Lately, our laboratory has focused on muscle disuse and the study of the causes of muscle weakness, from muscle morphological adaptations (Franchi et al. MSSE 2022) and the instability of the neuromuscular junction occurring after short-term bed rest and limb suspension (Monti et al. 2021; Sarto et al. 2022), to the study of single fibre proteomics to

identify the molecular remodelling of muscle unloading (Murgia et al. 2022). With a short journey from whole muscle to molecular adaptations to disuse conditions, this presentation aims to unravel some of the nueromuscular responses to unloading in space flight and with simulated micro-gravity conditions, trying to answer a simple question: "Can we really get to Mars and have a walk?". Moreover, new unpublished data (at the present time) regarding specific exercise countermeasures after a period of muscle unloading will be presented, with the aim to spark a discussion between sports scientists, exercise physiologists, and biomechanics experts, on what could be the best exercise strategies to counteract disuse atrophy.

Invited Symposium

IS-MH01 Exercise, Aging, and Metabolic Health: Decoding Intracellular and Extracellular Redox Signals

AGEING INDUCES ATTENUATED RESPONSES OF SKELETAL MUSCLE TO CONTRACTILE ACTIVITY: MECHANISMS AND EFFECTS

JACKSON, M.
UNIVERSITY OF LIVERPOOL

Minor episodes of denervation of skeletal muscle fibres occur throughout life and are rapidly repaired. Substantial denervation of muscles occurs as a result of trauma and disease and can lead to severe atrophy and eventual loss of the muscle fibres. Age-related loss of skeletal muscle mass and function (sarcopenia) is associated with loss of innervation of groups of muscle fibres and loss of motor neurons. Ageing related changes in muscle are also associated with dysregulation in the generation and/or handling of reactive oxygen species (ROS) in muscle. In normal physiology generation of ROS and redox signalling pathways play an important role in mediating specific responses of skeletal muscle to contractile activity. This process involves generation of ROS at specific sub-cellular sites in the muscle fibres. We have investigated the role of denervation in controlling ROS activities within muscle. Data from experimental models in which ROS regulation is modified, such as mice lacking SOD1 and those in which muscles undergo experimental denervation indicate that loss of motor neuron integrity leads to large increases in mitochondrial peroxide generation in the denervated muscle fibres. Furthermore, this increase occurs in mitochondria of neighbouring innervated fibres indicating a propagation of the process within the muscle. This local increased generation of peroxides by mitochondria appears to affect overall muscle redox homeostasis leading to oxidative damage and to dysregulation of adaptive responses to contractile activity. Implications for prevention and treatment of sarcopenia will be discussed.

SUBCELLULAR REDOX SIGNALING CONTROLLING SKELETAL MUSCLE METABOLISM IN HEALTH AND DISEASE

HENRIQUEZ-OLGUIN, C.
UNIVERSITY OF COPENHAGEN

Regular physical activity is a cornerstone of health, staving off aging and diseases such as type II diabetes and cardiovascular disease. Acute exercise introduces a multifaceted intracellular stress, with numerous post-translational modifications believed to underpin the health benefits of sustained exercise training. Reactive oxygen species (ROS) are posited to serve as second messengers, triggering cytoprotective adaptations such as the upregulation of enzymatic scavenger systems. However, a significant knowledge gap exists between the generation of oxidants in muscle and the exact mechanisms driving muscle adaptations. Over the past decade, our research has shed light on the compartmentalized sources of ROS—specifically mitochondria and the membrane-bound NADPH oxidase complexes (NOX)—and their contributions to immediate and long-term exercise responses. We discovered that NOX2, in particular, plays a pivotal role in the acute response to exercise, driving the expression of genes that underpin adaptation. Our innovative use of NOX2 inhibitors, mitochondria-targeted antioxidants, and advanced imaging techniques has revealed that NOX2 is a primary source of cytosolic H2O2 during exercise in vivo, essential for the translocation of the glucose transporter GLUT4 and subsequent glucose uptake in muscle. This presentation will describe the cellular mechanism of how exercise improves redox fitness in skeletal muscle to improve muscle function and insulin sensitivity.

EXERCISE-INDUCED SYSTEMIC RESPONSE: THE ROLE OF CIRCULATING EXTRACELLULAR VESICLES

CAPOROSSI, D.
UNIVERSITY OF ROME FORO ITALICO

Regular physical exercise (PE) leads to a systemic adaptation to redox homeostasis perturbation, one of the hallmarks of exercise adaptation. Extracellular vesicles (EVs) circulating in the body and secreted from various cell types, including skeletal muscle cells, contain various regulatory molecules and mediate intercellular communications and tissue crosstalk. Studies have shown that PE can alter the molecular composition of EVs, impacting their ability to communicate with other cells and modulate physiological processes. Considering that the health-related benefits of a physically active lifestyle are partially driven by various bioactive molecules released into the circulation during exercise, collectively termed "exerkines", there has been a rapidly growing interest in the role of EVs cargo as "carriers" in the multi-systemic, adaptive response to exercise. Indeed, a potential mechanism by which plasma EVs released during exercise impact ageing and diseases related to redox impairment is increased delivery of redox components, such as redox transcription factors and

antioxidants. Thexerciseis presentation will offer a general overview on the biology of exercise-induced EVs and their putative role on health maintainance and disease prevention, with a focus on redox homeostasis control.

OP-AP04 Pacing statistics

PACING STRATEGIES IN ELITE INDIVIDUAL MEDLEY SWIMMERS: A DECISION TREE APPROACH

CHANG, C.K.
NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: This study aims to investigate the pacing strategy and the importance of the four different stroke in men's and women's 200- and 400-m individual medley competitions in Olympic Games and World Swimming Championships between 2000 and 2021, excluding 2008 to 2010.

METHODS: The time in each lap and overall race were retrieved from the World Aquatics website. The final data comprised a total of 1937 data points (1052 for men, 885 for women) for the 200-m event and 1192 data points (607 for men, 585 for women) for the 400-m event. The standardized time for each stroke was calculated by dividing the actual time by a reference time specific to each stroke to accommodate the inherent disparities among the four strokes and the impact of the diving start in butterfly. The reference time was derived from the respective laps in single-stroke finals in the in the 2017 World Swimming Championships. A decision tree method was applied. The binary dependent variables were qualified or non-qualified in heats and semifinals, and medalists or non-medalists in finals. The independent variables were the pace in each stroke, represented by the ratio of standardized time in the specific stroke to the sum of standardized time in all four strokes. A total of 10 decision trees with the Classification and Regression Tree algorithm were established: heats, semifinals, and finals in men's and women's 200-m medley; and heats and finals in men's and women's 400-m individual medley. The decision tree models was established. The binary dependent variables were qualified or non-qualified in heats and semifinals, and winning medals in finals. The independent variables were the ratio of standardized time in each stroke to the sum of standardized time in all four strokes. The normalized importance of each stroke in each decision tree was calculated.

RESULTS: In men's and women's 200-m and 400-m individual medley, butterfly held the highest normalized importance in winning medals in the finals. The pace in butterfly was the first node in eight of the 10 decision trees, except men's 200-m semifinal and 400-m final, in which backstroke was the first node. The cut-off values for pace in butterfly in these eight models indicated that a pace larger than 0.236–0.245, i.e. spending relatively longer standardized time, in butterfly was associated with a higher likelihood of being qualified or winning medals in these competitions. It is noteworthy that the pace in this study is relative to each swimmer's performance in all four strokes.

CONCLUSION: Elite swimmers who spend a higher ratio of standardized time in butterfly is associated with a higher likelihood of winning medals or qualifying for the next stage in most international men's and women's 200-m and 400-m individual medley. Excellence in butterfly is the most crucial determinant in success in individual medley events while proficiency in at least one other stroke enhances the likelihood of winning.

BEYOND PACE: PREDICTING 1500M FREESTYLE TIMES WITH MULTI-FEATURE RANDOM FORESTS

RUSSOMANNO, T.
TUM / UNB

INTRODUCTION: Advances in technology have led to a loads of data in many sports, making data-driven models increasingly popular for performance analysis (Silva. et.al., 2007). Different models have been applied to swimming, predicting individual event performance based on various datasets (Wu et.al.,2021). In long-distance swimming, the pace strategy (PS) follows a U-shaped curve (Lara and Del Coso, 2021). This means professional swimmers start and finish fast, maintaining a relatively consistent speed with minor fluctuations in between. This study investigates the use of a Random Forest model to predict final race times based on athletes heat times and pace strategy.

METHODS: Race data from five Olympic Games (Sydney, Athens, Beijing, Rio, and Tokyo) were analyzed, containing both heats and finals data. Data were obtained from the FINA website (https://www.fina.org), providing split times for every 50m and final times for each race. A total of 174 races were analyzed. The dataset was divided into two parts: one for training the model (heat data) and the other for evaluation (final data).Relevant features like mean time, speed at different distances, and total time were selected for model training. A Random Forest model was trained with optimal hyperparameters: 200 estimators, max_depth =8, max_features=sqrt, min_samples_leaf=1, random_state=42.

To evaluate the models performance, the following metrics were used: Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Mean Absolute Error (MAE), R-squared and Explained Variance Score.

RESULTS: On the training data, the model achieved a Mean Squared Error (MSE) of 5.09, Root Mean Squared Error (RMSE) of 2.25, Mean Absolute Error (MAE) of 1.708, R-squared of 0.953, and Explained Variance Score of 0.968. On the final dataset, the model achieved an MSE of 32.53, RMSE of 5.70, MAE of 4.40, R-squared of 0.94, and Explained Variance Score of 0.94. This indicates a slight decrease in model performance on the new data, with an average prediction error of

around 5.7 seconds. In a race lasting approximately 14 minutes, this translates to an error of less than 0.58% of the total time.

CONCLUSION: The analysis consistently revealed a U-shaped pace strategy profile employed by all athletes across all races, regardless of whether they were competing in heats or finals. This finding highlights the consistency of this approach in 1500m swimming. The chosen Random Forest model demonstrated worthy performance on the training data, explaining over 95% of the variance in total final times. This indicates the models ability to effectively learn the underlying patterns and relationships within the dataset. Still, when applied to the evaluation data (final times), the models performance exhibited a slight decrease, resulting in an average prediction error of approximately 5.7 seconds. This study showcases the promising potential of Random Forest regression for predicting swimming times. Utilizing features derived from both heat and final performance.

A RACE BETWEEN TWO RACES: POSITIONING AND POWER DEMANDS DURING CYCLING IN A SPRINT TRIATHLON WORLD CHAMPIONSHIP

NOLTE, S., QUITTMANN, O.J.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: Drafting in short-distance triathlon cycling introduces variable power demands [1,2]. Performance evaluations solely based on cycling split times may overlook the differing power requirements experienced by riders even within the same bike group. Factors like positioning within the bike group could influence power demands and subsequently initial fatigue in the following run segment of a triathlon [3].

METHODS: We analyzed power data and television-based positional information from the 2020 male sprint triathlon World Championship event held in Hamburg. Specifically, we focused on five of the eight riders from the leading bike group, examining their power profiles and power distributions. Employing hierarchical Bayesian models, we analyzed the association between positioning within the group and the power demands during accelerations following turns. Our study was preregistered and has open data and code available.

RESULTS: Within the same bike group, athletes showed distinct power profiles and employed different positioning strategies. Notably, as athletes positioned themselves further back during a turn, they demonstrated higher peak power (+24.2 W [4.8; 36.7] per position; mean [95% credibility interval]) and 10 seconds mean power (+19.3 W [10.5; 27.1]) during subsequent accelerations. However, the effect of positioning was less pronounced on the 20 seconds mean power (+6.3 W [-1.4; 13.6]), and it had a negative impact on the 20 seconds mean power before the turn (-13.4 W [-20.8; -4.99]).

CONCLUSION: The positioning of athletes during cycling in a triathlon can impact the power demands, potentially influencing the performance during the subsequent running leg. Our findings indicate that to reduce power demands, athletes should position themselves at the front of the group during turns and towards the back for the remainder of the cycling segment. However, employing this strategy will likely compromise cooperative group work. Therefore, athletes and coaches must develop positioning strategies based on data and experience, tailored to individual abilities. Future studies should aim to correlate power variability with running performance in races, while accounting for individual running performance levels.

DIFFERENCES IN PACING DURING A 100KM ULTRA-TRAIL MARATHON BETWEEN TOP-10 AND NOT TOP-10 FINISHERS.

DE WAAL, S., JACOBS, S., LAMBERTS, R.

UNIVERSITY OF STELLENBOSCH

INTRODUCTION: Pacing strategies during endurance efforts are learned behaviours which vary depending on athlete experience, race length, and terrain [1]. Previously, optimal ultra-trail marathon running pacing strategies have been described as 'steadier' [2] or by 'limiting' fluctuations in speed [3]. These pacing analyses were limited by electronic timing systems which use indiscriminate distances between checkpoints. Therefore, the aim of this study was to determine the pacing strategies and relative importance of uphill, downhill and level running for ultra-trail marathon performance in top 10 (TOP-10) runners and non-top 10 (NOT TOP-10) runners in a 100 km ultra-trail marathon.

METHODS: Fifty male finishers (TOP-10: n = 6, NOT TOP-10, n = 44) and forty-six individual segments (1.5 ± 1.2 km) were analysed based on 2021 100 km UTCT STRAVA data. Twenty-three uphill (net gradient > 1.0%), 16 downhill (net gradient <-1.0%) and 7 level (net gradient between +1.0% - -1.0%) were analysed. Individual segment speeds, normalised to average race pace (segmentrel), and CV% were used to identify pacing strategies. Mann Whitney-U tests were used to compare TOP-10 and NOT TOP-10 finishers. Spearman Rank correlations were used to measure the association between overall race performance and uphill, downhill, and level running performance. Significance was set at $p<0.05$ for all tests.

RESULTS: Uphill running had the strongest relationship with overall performance ($r = 0.826$, $p <0.01$). Substantially weaker relationships between overall running performance and level ($r = 0.402$, $p<0.01$) and downhill ($r = -0.382$, $p<0.01$) running performance were found. The CV% was significantly lower in TOP-10 (32.10 ± 1.81) than NOT TOP-10 (35.39 ± 4.43) ($U = 24$, $r = 0.46$, $p <0.01$), with both groups characterised by a positive pacing strategy. In 12 of the first 17 segments, TOP-10 fin-

ishers ran significantly slower (segmentrel) than NOT-TOP 10 finishers ($p < 0.05$). Inversely, TOP-10 finishers ran 7 of the last 11 segments (segmentrel) quicker than NOT-TOP 10 finishers ($p < 0.05$).

CONCLUSION: Uphill running performance remains a valuable measure of overall trail running performance as it represents a higher percentage of overall running demand. Sport scientists and laboratory technicians should continue to use uphill exercise tests to determine variation in ultra-trail marathon performance [4]. TOP-10 runners have diminished decay in initial running speed than NOT TOP-10 runners, despite a generally high variation in pace and net positive split in ultra-trail running. Neuromuscular fatigue [5] may contribute to the disparity in segmentrel between TOP-10 and NOT TOP-10 runners during the latter phases of an ultra-trail marathon.

AN EMPIRICAL STUDY ON THE SPEED CHARACTERISTICS OF MALE 20KM RACE WALK ATHLETES AT DIFFERENT PERFORMANCE LEVELS

PEI, L.

CHINIA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: This study aims to investigate the correlation between athletes rankings and various segmented and Speed indicators, while contrasting the disparities in Speed patterns and Speed indicators among athletes of different proficiency levels.

METHODS: A cohort of 47 athletes who completed the 20km race walk at the 2023 Budapest World Athletics Championships was selected for this study. Correlation analyses were conducted on rankings and different segmented and Speed indicators, elucidating differences in Speed patterns and Speed indicators among athletes with varying skill levels. The study seeks to unveil Speed rhythm patterns conducive to maximizing athletes potential. Utilizing a quasi-experimental design, athletes were categorized into three groups based on their performance in the competition. Descriptive statistics were applied to indicators such as segmented Speeds per 1km, segmented Speeds per 5km, starting Speed, peak Speed, minimum Speed, sprint Speed, and various Speed coefficients. Correlation analyses were performed when the data exhibited significance under the assumptions of normality and variance analysis. Following the identification of data disparities, post-hoc tests were conducted to specifically compare differences between pairwise groups, as per the requirements of English-language journals.

RESULTS: There is a significant negative correlation between rankings and segmented Speeds at 1-5km, 6-10km, and 16-20km compared to the average Speed. However, there is no correlation between rankings and segmented Speed at 11-15km compared to the average Speed. Athletes of different proficiency levels exhibit variations in each 5km segment, and as the segment distance progresses, the differences between the groups also increase accordingly. The correlation between rankings and minimum Speed, as well as sprint Speed, is greater than the correlation with starting Speed and peak Speed. In most segments, there are significant differences in the averages between athletes of different proficiency levels. Moreover, as the segmented Speed progresses, the differences between proficiency levels also increase.

CONCLUSION: High-level athletes show minimal Speed variation throughout the entire race, with segmented Speeds consistently higher than the starting Speed, and relatively small differences between segment Speeds. In contrast, low-level athletes are more likely to experience a continuous decline in Speed, with a larger proportional decrease and an earlier occurrence of segmented Speeds falling below the starting Speed. Peak Speed tends to occur earlier, typically around the 2km mark after the start of the race in the mens 20km race walk event. The optimal Speed rhythm for maximizing athlete potential in the mens 20km race walk is characterized by minimal overall Speed variation, especially in starting Speed, peak Speed, and segment Speeds, with peak Speed occurring late and starting Speed lower than most other segmented Speeds. Recommendations include emphasizing improvement in peak Speed and starting Speed for competition among high-level athletes, creating gaps in the 10-15km segment, and enhancing the pace in the later stages. For low-level athletes, the focus could be on improving minimum Speed to enhance Speed reserve capacity.

OP-PN13 Nutrition/Low energy availability

LOW ENERGY AVAILABILITY AND LEPTIN LEVELS OF RECREATIONAL AND ELITE FEMALE CROSSFIT ATHLETES - PRELIMINARY DATA FROM AN EXPLORATORY CROSS-SECTIONAL STUDY.

NAKAMOTO, F.P., QUARESMA, M., SANTOS, C., NARESSI, L., ALMEIDA, H., SILVA, N., MANCINI, S., HACKER, W., ALVARES, L., FERREIRA, R., SANTOS, R.

CENTRO UNIVERSITÁRIO SÃO CAMILO

INTRODUCTION: CrossFit® (CF) is characterized as a constantly varied, high-intensity, functional movement training program, performed with little or no rest between bouts, combining strength and endurance exercises. Due to CF characteristics, female CF practitioners may be at risk to experience low energy availability (LEA), which is the etiological process underpinning several disturbances such as hormone imbalance and consequent Relative Energy Deficiency in Sports (RED-S). The aim of this study is to verify possible LEA and leptin levels of recreational and elite female CF athletes.

METHODS: This is a cross-sectional study with nonprobability sampling. Inclusion criteria: healthy female CF practitioners aged 18-39 years, CF training experience ≥1 year; 5-7 training sessions (5-7 hours) per week for ≥6 months for the recreational practitioners group (RG); ≥12 hours of CF practice per week for ≥6 months for the elite group (EG). Subjects visited the laboratory once. They answered a health and sociodemographic questionnaire plus the Low Energy Availability in Females Questionnaire (LEAF-Q). Resting energy expenditure (REE) via indirect calorimetry and body composition (bioelectrical impedance analysis) were assessed in a fasting state, followed by blood test (levels of leptin). Data were analyzed using Jamovi® 2.3.21 version.

RESULTS: Data of a preliminary sample of 12 subjects are presented as mean (SD). Students t-test showed no differences regarding age (31.7 (5.6) and 30.2 (7.2) years), body mass index (23.9 (2.1) and 25.6 (1.8) kg/m2), REE (1645.7 (184.6) and 1595.8 (147.4) kcal/day), and daily energy intake (EI: 1569.7(774.2) and 1847.2(422.1) kcal/day) between RG (n = 6) and EG (n = 6), respectively. Body fat percentage (BF%: 23.6(3.8) and 18.5(3.0); p = 0.028), fat free mass (FFM: 45.1(4.0) and 55.4(4.1) kg; p = 0.001), and leptin levels (7.1(2.0) and 0.8(0.1) ng/mL; p < 0.001) were significantly lower in the EG (bellow reference range). About 90% of leptin levels variability is explained by the multiple regression model (R2: 0.895; p < 0.001). After controlling for group, EI, and BF %, the linear regression model showed that group (EG) was negatively associated with the levels of leptin, independently of EI and BF % (B = -5.820; 95% IC: -7.43 to -4.22; p < 0.001). EA calculation resulted in 26.29 and 20.37 kcal/kg FFM/day for RG and EG, respectively. LEAF-Q scores were 4.7 (RG) and 7.0 (EG).

CONCLUSION: We found probable LEA in female CF practitioners, especially in the EG. An EA of < 30 kcal/kg FFM/day is typically defined as clinically LEA, which in mid- and long-term results in health implications with impairment of many body systems. It has been shown that LEA suppressed the 24-h mean and amplitude of the diurnal rhythm of leptin in other female athletes, but this is the first study to show it in CF elite female athletes. It might precede other perceived disturbances associated with RED-S in this population. Our results are preliminary and further investigation is necessary.

DEVELOPMENT AND VALIDATION OF A RISK-ASSESSMENT TOOL FOR ENERGY DEFICIENCY IN YOUNG ACTIVE FEMALES: THE FEMALE ENERGY DEFICIENCY QUESTIONNAIRE (FED-Q)

SALAMUNES, A.C., WILLIAMS, N., KOLTUN, K., KURUPPUMULLAGE DON, P., DE SOUZA, M.J.
PENNSYLVANIA STATE UNIVERSITY

INTRODUCTION: Athletes who fail to consume sufficient energy are at risk of serious consequences to reproductive and skeletal health. Estimating energy availability has clear limitations for real-life assessments. Metabolic hormones and resting metabolic rate tests are precise measurements, but may not be feasible in clinical practice. Questionnaires may be valuable to estimate the risk of energy deficiency. We aimed to develop and validate a risk-assessment tool for energy deficiency in young exercising women using disordered eating subscales and self-reported health-related information.

METHODS: This study is a retrospective analysis of seven studies in competitive female athletes and recreationally active women [n=202, age 21.7±0.3 years, body mass index (BMI) 21.21±0.14 kg/m2, presented as mean±S.E.M.]. Participants completed the Women's Health and Exercise Laboratory's Health, Exercise and Nutrition Survey (HENS), the Three-Factor Eating Questionnaire (TFEQ), and the Eating Disorder Inventory – 3 (EDI-3). Fasting serum total triiodothyronine (T3) was assessed with chemiluminescence. Participants were categorized as energy deficient if they had T3 <73.2 ng/dL, and as energy replete otherwise. The following variables were tested as potential predictors of low T3: age of menarche and gynecological age; HENS items related to disordered eating, menstrual status, and bone health; cognitive restraint (CR) from TFEQ; and Perfectionism, Body Dissatisfaction (BD), and Drive for Thinness from EDI-3. The dataset was divided into a model set (n=152; 21.8±0.3 years, 21.23±0.16 kg/m2) and a validation set (n=50; 21.6±0.4 years, 21.15±0.3 kg/m2). The model set was used to fit stepwise logistic regressions on 500 random iterations using Akaike information criterion. Predictors included in at least 400 models were used in a final logistic regression model, which was tested on the validation set to determine sensitivity and specificity.

RESULTS: The predictors included in the final logistic regression model were: BMI; number of menstrual cycles experienced in the last 6 months (from HENS), a binary predictor to control for oral contraceptive use, CR from TFEQ, and BD from EDI-3. When tested on the validation set, the model yielded a 73.7% sensitivity and a 93.5% specificity to detect T3 <73.2 ng/dL, therefore yielding an 86% accuracy. Using the clinically used T3 cut-off of 80 ng/dL, the model yielded 75% sensitivity, 96.7% specificity, and 88% accuracy.

CONCLUSION: The model has yielded high accuracy to predict the probability of having energy deficiency and was validated against a reliable physiological marker, serum T3 concentrations. The Female Energy Deficiency Questionnaire was developed from a large dataset of exercising women from various competitive and recreational sports; therefore, it is applicable to a wide population. At present, this is the only questionnaire that has been validated to be used as an indicator of energy deficiency in exercising women beyond endurance athletes and dancers.

SYMPTOMS OF EATING DISORDERS AMONG SWEDISH FEMALE ELITE ATHLETES AND RECREATIONAL ACTIVE WOMEN

MELIN, A., AHLGREN, M., KJAER, J.B., LINNÉR, S., LOSSIUS, L., PAGELS, P., POJSKIC, P., RAGNARSSON, T., EDLUND, K.
SPORTS SCIENCE

INTRODUCTION: Symptoms of eating disorders (EDs) have been reported to be more frequent within the elite sport environment compared to the general population. In this study we aimed to investigate symptoms of EDs among female elite athletes and recreational active women, and the associations to exercise behaviour and perceiving well-being.

METHODS: Swedish national team athletes [Tier 4 (n=172), 24.8 ± 6.1 years of age] from 24 sport disciplines, and aged matched recreational active women [Tier 1-2 (n=100), 25.8 ± 6.7 years of age] were recruited via sport organisations and social media. The protocol of this two-step study included an anonymous on-line survey comprising of the Eating Disorder Examination Questionnaire [(EDE-Q); a Global score >2.30 categorised participants as having symptoms of EDs], the Major Depression Inventory [(MDI) a total score >25 categorised participants as having moderate/severe depression], the Exercise Addiction Inventory [(EAI) a total score >24 categorised participants as having exercise addiction], and the Low Energy Availability in Females Questionnaire to assess menstrual cycle disturbances (MCD) and gastrointestinal (GI) problems [a GI-score >3]. Participants with symptoms of EDs who providing their contact information were invited to a clinical EDE interview for differential diagnosis (DSM-5).

RESULTS: Among all subjects (25.2 ± 6.3 years, training 13.3 ± 6.6 h/week), 27% had symptoms of EDs, of which 40% participated in the clinical EDE interview confirming an ED diagnosis in all but one participant. More of the participating recreational active women had symptoms of EDs compared to the elite athletes (36% vs. 21%, p=0.010). There were no differences in training load (14.3 ± 7.1 vs. 13.0 ± 6.2 h/week, p=0.167), BMI (22.7 ± 2.8 vs. 22.7 ± 2.9, p=0.840) or the frequency of MCD (34% vs. 29%, p=0.567) between participants with and without symptoms of EDs. Participants with symptoms of EDs had a greater weight fluctuation (11.8 ± 8.5 vs. 9.6 ± 6.2, p=0.019), a higher GI-score (3.4 ± 2.3 vs. 2.5 ± 1.8, p=0.004), and more reported having moderate to severe depression (49% vs. 14%, p<0.001), exercise addiction (42% vs. 20%, p=0.001) as well as perceived poorer general health (p<0.001), worse life-situation (p<0.001), and lower self-esteem (p<0.001), compared to those without ED symptoms.

CONCLUSION: In contrary to earlier reports, we found that symptoms of EDs confirmed by diagnostic interviews were more common in this group of Swedish recreational active women than the included national team athletes. The surprisingly high prevalence of symptoms of EDs in the present study could be due to respons bias (e.g., people with EDs are more prone to participate). However, the overwhelming association between ED symptoms and poor well-being emphasise the need for implementing prevention strategies in both the general population and within Swedish elite sport. Future intervention studies focusing on primary, secondary and tertiary prevention initiatives are warranted.

EXPERT CONSENSUS ON DIETARY STRATEGIES FOR BODYBUILDERS AND POWERLIFTERS BEFORE AND AFTER COMPETITION: A DELPHI STUDY

BUECHEL, C., MINEHAN, M., ETXEBARRIA, N., PUMPA, K.

UNIVERSITY OF CANBERRA

INTRODUCTION: Natural bodybuilding and powerlifting require repeated cycles of weight reduction and weight gain to optimise body composition for competition. Energy restriction in athletes can be associated with risks related to low energy availability, such as disruptions to metabolic rate and endocrine systems [1]. Despite abundant research on weight loss strategies for competition in athletes, the recovery period after achieving weight loss remains poorly understood. This study seeks to identify strategies used in practice to guide fat loss and energy restoration in bodybuilders and powerlifters before and after competition.

METHODS: Fifteen international experts including academics, coaches, and sports dietitians experienced working with bodybuilders and powerlifters, were recruited to participate in a 3-round Delphi survey. The first round consisted of open-ended questions relating to weight management strategies. A thematic analysis was used to formulate statements for the Round 2 survey where participants were asked to rate their level of agreement using a 5-point Likert scale. Statements that did not reach a consensus of over 70% were revised and re-circulated in Round 3.

RESULTS: The retention rate was 80% across the 3 surveys. Round 1 generated 85 statements used in Round 2, consisting of the themes "multidisciplinary support", "weight loss time frames", "weight loss nutrition", "peaking and competition day", "negative impacts of weight loss", and "post-competition recovery". Fifty-five statements reached consensus and the remaining were revised into 41 statements (30 revised and 11 new) for Round 3. The final survey formed consensus on 20 statements, leaving 21 statements without consensus, primarily on topics of refeeding strategies within "weight loss nutrition" and "post-competition recovery". Experts agreed that individualised athlete weight management strategies required multidisciplinary teams for health and performance. Additionally, bodybuilders reduce body weight to a greater extent than powerlifters, requiring different recovery strategies post-competition.

CONCLUSION: In bodybuilders and powerlifters, key strategies for fat loss during competition preparation include aiming for 0.5-1% body weight loss per week, maintaining high protein intake, periodising carbohydrates, and using diet breaks and refeeds to support adherence. Individual plans for post-competition energy restoration should be in place, catered towards off-season body composition goals. Bodybuilders would benefit from an acute increase in energy intake alongside body weight, followed by controlled refeeding into the off-season.

ARE ENDURANCE ATHLETES AT HIGHER RISK OF DEVELOPING FOOD ALLERGY OR FOOD INTOLERANCE THAN THE GENERAL POPULATION? A PILOT STUDY.

HALL, B., SIKORA, M., KAMINSKI, T., ZAJAC, T., SIATKOWSKI, S., MIKOLAJCZYK, R., PILZAK, K., ZEBROWSKA, A.
JERZY KUKUCZKA ACADEMY OF PHYSICAL EDUCATION IN KATOWICE, POLAND

INTRODUCTION: Long-term strenuous exercise can compromise the intestinal barrier, leading to the escape of undigested dietary and microbial molecules into the blood, triggering an inflammatory response. This may cause sensitization to normally harmless substances like food proteins, potentially exacerbated by artificial ingredients in sports supplements. Such adverse reactions, whether immune-mediated (food allergies) or not (food intolerances), can affect athletes performance, nutrition, and health. Despite the rising prevalence of allergic diseases, research on food allergies in athletes, especially endurance athletes, remains limited.

METHODS: Twenty-one healthy endurance athletes (female n = 8, male n = 13), aged 39.1±5.3 years, participating in long-distance running, cycling, or triathlon for approximately 7.3±5.6 years took part in the study. Their body composition was evaluated by means of bioelectrical impedance analysis (InBody 570, Seoul, South Korea) and aerobic fitness during a graded exercise test performed on a treadmill (h/p/cosmos, Nussdorf-Traunstein, Germany) or a cycle-ergometer (Lode Excalibur Sport, Groningen, Netherlands). The participants were asked to complete the validated EuroPreval/PAFA questionnaire on food allergy and food intolerance. Venous blood for determination of specific IgE was withdrawn from the cubital vein at rest.

RESULTS: The participants had low body fat percentage (females: 18.0±6.4 vs. males: 13.3±5.9%) and high aerobic fitness, as indicated by their VO_2max, particularly in females (females: 48.1±4.8 vs. males 48.3±5.6 ml/kg/min). A majority (71.4%, n = 15) of participants reported adverse reactions to food giving an estimated prevalence of 71.4% (95%CI 47.8 – 88.7%). The most frequently reported problem foods were: cow's milk (33.3%), pea (33.3%) and wheat containing gluten (26.7%). Energy gels or beverages, and protein sport supplements induced adverse reactions in 20.0% and 13.0% of those reporting adverse reactions, respectively. The majority of reported symptoms and their time of onset indicated food intolerance rather than food allergy. Only three individuals were sensitised (IgE ≥ 0.35 kU /L) to crustaceans (n = 1), hen's egg white (n = 1), whilst the third participant was sensitised to eight foods: wheat flour, rye flour, rice, almond, tomato, carrot, celery, and potato. None of these foods were reported in the questionnaire by these individuals.

CONCLUSION: Self-reported adverse reactions to food, particularly food intolerances, are common among endurance athletes and may exceed general population rates. The findings underscore the need for larger studies to verify these preliminary observations and explore the implications for athlete health and performance management. The study recruitment is in progress.

NEW INSIGHTS INTO EXERCISE-INDUCED SKELETAL MUSCLE GENE EXPRESSION IN MEN AND WOMEN

TAYLOR, D., REISMAN, E., GARNHAM, A., HOFFMAN, N., HAWLEY, J., CARUANA, N., BISHOP, D.J.
VICTORIA UNIVERSITY

INTRODUCTION: Exercise stimulates numerous adaptations in skeletal muscle, including increased mitochondrial content. The currently accepted dogma proposes that transient changes in the mRNA of mitochondrial genes after a single session of exercise are a major determinant of subsequent adaptations to training. However, the use of only 1 or 2 time-points post exercise, small sample sizes, and a lack of consideration for the effect of sex, has left major gaps in our understanding of exercise-induced mitochondrial gene expression.

METHODS: RNA sequencing was performed on muscle biopsies collected before, during, and 0, 3, 6, 9, 12, 24, and 48 hours following a single session of high-intensity interval exercise from 20 healthy untrained men (27.3 ± 6.3 y; 179.6 ± 10.2 cm; 81.5 ± 12.5 kg) and 20 healthy untrained women (27.6 ± 5.6 y; 166.5 ± 7.8 cm; 68.0 ± 9.9 kg). The exercise session consisted of 4 x 4-min intervals at an intensity between each participant's lactate threshold (LT) and peak power output (PPO), interspersed with 2 min of recovery.

RESULTS: Our adoption of the most extensive post-exercise biopsy time course to date allowed us to identify more than 10,000 genes never previously reported to be differentially expressed by aerobic exercise; the vast majority were identified 9 to 48 hours post-exercise. Of these, 1016 were mitochondrial genes, with over 800 not previously reported to be altered by aerobic exercise. Soft clustering of the 1,016 mitochondrial differentially expressed genes revealed six characteristic patterns of expression, including clusters of early (3-6 h), mid (9-12 h), and late (24-48 h) responding genes. We also identified 675 mitochondrial genes that were downregulated 24-48 h post exercise, including most oxidative phosphorylation complex subunits. Transcription factor enrichment analysis using an aggregated ChIP-Seq dataset library identified the MYC transcription factor network as a key regulator for many of these gene clusters. Similarly, p53 was identified as an important regulator of late-responding genes. Although there were over 500 genes detected as differentially expressed between men and women at baseline, sex had a minimal effect on the expression of mitochondrial genes in response to exercise.

CONCLUSION: Our unique study was able to produce the most extensive description to date of the exercise-induced transcriptome, with over 14,000 genes identified as differentially expressed. Interestingly, several diverging patterns of expression for mitochondrial genes were found, indicating regulation by various transcriptional factor networks and potentially a high degree of variance in post-transcriptional regulation. By obtaining a statistical power above 0.85, and use of an exercise intensity based on both LT and PPO, we were able to detect fewer sex differences for exercise-induced mitochondrial gene expression than previously assumed.

DYNAMIC PROTEOMIC RESPONSES TO AEROBIC VERSUS RESISTANCE TRAINING IN HUMAN SKELETAL MUSCLE.

STEAD, C., THOMAS, A.C.Q., D'SOUZA, A.C., MCKENDRY, J., LIM, C., SIEKMANN, I., PHILLIPS, S.M., BURNISTON, J.G.
LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: We investigated muscle adaptations to aerobic training (AT) versus resistance training (RT) during the early untrained-state versus longer-term trained-state using novel deuterium oxide labelling and proteomic techniques. Our study aims to generate new insight into training mode-specific muscle adaptations by measuring protein-specific changes in abundance and synthesis rates.

METHODS: In a within-subject longitudinal design, 14 (8F/6M) healthy individuals (20± 2y, body mass: 70±21 Kg) completed 10-wks of thrice weekly unilateral resistance (RT: 3 sets × 10-12 reps 80% 1-repetition maximum (RM) leg press and leg extension) and unilateral aerobic (AT: 4 × 5 min one-legged cycling at 65% Wattmax) training. Biopsies were taken at the start and end of a 1-week free-living period prior to training (Baseline), the 1st-wk of training (Early), and the 10th-wk of training (Later). Participants consumed deuterium oxide across all 3 study periods. Muscle samples (n = 5 individuals, 1M/4F) were analysed by liquid chromatography tandem-mass spectrometry. Within-subject 2-way ANOVA investigated interactions between exercise mode (RT vs AT) and study period (Baseline x Early x Later) in protein-specific abundance and synthesis rates. Significant differences ($p<0.05$) were investigated using bioinformatic analyses (proteins reported as UniProt identifiers).

RESULTS: RT increased ($p<0.005$) 1RM leg press 116% (+65±10kg) and 1RM leg extension 76% (+16±5kg), whereas AT increased ($p=0.025$) unilateral Wmax 17% (+21±17W). Proteomic analysis quantified 2883 abundance and 1465 synthesis rates. Mixed-protein FSR (%/d) increased (34% NS) during Early RT only and was 15% above Baseline during Later RT and AT. Early RT increased the turnover of 22 (primarily myofibrillar) proteins, whereas Early AT increased the turnover of glycolytic enzymes and the abundances of 10 proteins of the KEGG pathway 'Oxidative phosphorylation' (OXPHOS; FDR = 0.03). Later AT increased the abundance of proteins associated with 'Cellular respiration' (FDR = 1.2e-17), including 16 Complex I (CI) subunits. Both RT and AT significantly increased abundance of 48 mitochondrial proteins, including 5 CI accessory subunits and regulators of mitochondrial quality (OPA1, MAIP1, AFG32, CHC10, MIC26, and GHITM). Later AT specifically increased the turnover of regulators of mitochondrial proteostasis, including the HSP70 co-chaperone BAG3 and eIF5A. Later RT specifically increased the turnover of 21 proteins, including glycolytic enzymes and regulators of mitochondrial morphology and quality control, such as CHCHD2 which increased ($p < 0.01$) in turnover rate from 5.7±4.9 %/d at Baseline to 13.6±2.8 %/d in Later RT.

CONCLUSION: AT and RT resulted in improvements in mitochondrial quality via training-mode specific changes in abundance and synthesis rates. Remodelling of CI was specific to AT, whereas RT increased in the abundance and turnover of proteins associated with mitochondrial quality independent of changes in OXPHOS catalytic subunits.

SINGLE-NUCLEI GENE EXPRESSION IN SKELETAL MUSCLE DOES NOT MIRROR A TRAINING-INDUCED INCREASE IN INSULIN SENSITIVITY IN INDIVIDUALS WITH TYPE 2 DIABETES

HANSEN, M.1, GROTHEN, J.E.R.2,3, KARLSEN, A.1, PEDERSEN, T.Å.2, SIDIROPOULOS, N.4, HELGE, J.W.1, DELA, F.1,5
1 DEPARTMENT OF BIOMEDICAL SCIENCES, UNIVERSITY OF COPENHAGEN, DENMARK 2 GLOBAL DRUG DISCOVERY, NOVO NORDISK A/S, DENMARK 3 NOVO NORDISK FOUNDATION CENTER FOR BASIC METABOLIC RESEARCH, UNIVERSITY OF COPENHAGEN, DENMARK 4 COMPUTATIONAL BIOLOGY, AI & DIGITAL RESEARCH, NOVO NORDISK A/S, DENMARK 5 DEPARTMENT OF BIOCHEMISTRY AND PHYSIOLOGY, RIGA STRADINS UNIVERSITY, LATVIA

INTRODUCTION: Training improves insulin sensitivity in patients with type 2 diabetes (T2D) (1), but the underlying mechanisms are only partly understood. Single-nuclei RNA-sequencing (snRNA-seq) offers the opportunity to study fibre type-specific gene expression changes. This is the first study to examine nuclei-specific gene expression changes in skeletal muscle in individuals with T2D and healthy controls (CON) in response to a short-term high-intensity training (HIIT) program. We hypothesised that snRNA-seq of muscle biopsies would reveal marked diabetes- and training-induced responses.

METHODS: Ten males with T2D (57±2 years, BMI 31±1 kg/m2, HbA1c 53±1 mmol/mol) and ten male CON (53±2 years, BMI 31±1 kg/m2, HbA1c 37±1 mmol/mol) completed two weeks of one-legged HIIT on a cycle ergometer. Insulin sensitivity (clamp + leg balance technique) was measured previously (2). We prepared a single nuclei suspension from muscle biopsies from untrained (UT) and trained (T) legs and used the 10X Genomics system for the preparation of snRNA-seq Libraries, which were sequenced using an Illumina NextSeq550snRNA-seq. QC, cluster identification and differential expression testing were analysed using the Seurat (v4), and we identified differentially expressed genes (DEGs) between two groups of nuclei using a Wilcoxon Rank Sum test. Fibre type distribution was confirmed through immunohistochemistry.

RESULTS: Insulin-stimulated leg glucose clearance was 33±24% higher in T legs compared to UT legs in both groups (2).

Single-nuclei RNA-sequencing in 38 biopsies yielded 135,225 nuclei in total, and we profiled 99,970 myonuclei. In the UT legs, there were 249 DEGs between the groups, with equal distribution between fibre types. When comparing UT and T legs, there were no differences between the number of DEGs in the groups (222 DEGs in CON and 234 DEGs in T2D).

Almost no genes related to the citric acid cycle, glycolysis, glycogenolysis, or beta-oxidation differed between the groups in the UT leg. In T2D there was no effect of training on genes related to glycolysis and glycogenolysis. However, CON had multiple DEGs for glycolytic and glycogenolytic enzymes (i.e. enolase, glycogen debranching enzyme, glycogen phosphorylase) in the type 2A and type 2X fibres in the T leg compared to the UT leg. There were no changes in fibre type distribution after training, and the immunostaining and the snRNA-seq fibre type distributions were in accordance with each other.

CONCLUSION: HIIT improves skeletal muscle insulin sensitivity, but the modest single-nuclei gene expression changes did not mirror this response. Mostly, genes related to glycolysis and glycogenolysis in type 2 muscle fibres displayed significant differences between the groups in response to training. Overall, the pattern of altered gene expressions does not seem to explain the marked change in muscle insulin sensitivity.

THREE BOUTS OF RESISTANCE EXERCISE NORMALIZE SR CA2+ HANDLING IN MYOTONIC DYSTROPHY TYPE I PATIENTS

HANDEGARD, V., ØRSTAVIK, K.2, LUNDE, P.K.3, SEYNNES, O.1, PAULSEN, G.1, LOUCH, W.E.3, RAASTAD, T.1

1. NORWEGIAN SCHOOL OF SPORT SCIENCES. 2. OSLO UNIVERSITY HOSPITAL. 3. OSLO UNIVERSITY HOSPITAL AND UNIVERSITY OF OSLO

INTRODUCTION: Myotonic Dystrophy type I (DM1) is the most common adult-onset muscular dystrophy and patients presents with muscle weakness. DM1 skeletal muscle show reduced expression of central Ca2+ handling proteins, such as the Ryanodine Receptor (RyR; 1) and the Sarcoplasmic Reticulum (SR) Ca2+ ATPase (SERCA; 2). Increased intracellular resting levels of Ca2+ has been shown in DM1 myotubes (1). Together these findings indicate disrupted Ca2+ homeostasis. The aims of this study were therefore to (1) establish if SR Ca2+ handling is different in DM1 patients compared to healthy controls, and (2) investigate if resistance exercise (RE) could alter SR Ca2+ handling in DM1 patients.

METHODS: DM1 patients (DM1) and healthy controls (Ctrl) underwent three bouts of unilateral moderate-heavy RE (leg press and knee extension), with 72 hours of recovery between bouts. Maximal force (MVC) of the knee extensors was measured at baseline and 5 minutes, 3, 24, 48, and 72 hours after bout 1, 72 hours after bout 2 and 24 hours after bout 3. M. vastus lateralis biopsies were obtained at baseline and 24 hours after bout 3. SR Ca2+ handling was investigated using a SR vesicle preparation. Muscle tissue homogenate was analysed for RyR, SERCA1a, SERCA2, Phospholamban (PLB; total and phosphorylated) expression using Western blotting. Baseline data were investigated with one-way ANOVA or t-test. Effects of RE were analysed with a mixed model with time and disease as fixed effects. Data are expressed as mean ± standard deviation.

RESULTS: MVC was not different between DM1 and Ctrls at baseline. DM1 had higher Ca2+ uptake rates than Ctrls, with no differences between DM1 and Ctrls in Ca2+ release rates. DM1 also showed higher SR Ca2+ load compared to Ctrls. No baseline differences were detected in expression of SERCA1a, SERCA2, PLB, p-PLB, or RyR, although p-PLB/PLB ratio tended to be higher in DM1 (p=0.068). MVC was reduced by 14 % 3 hours after RE in DM1 (p=0.037), before returning to baseline whereas Ctrls increased from baseline to 24 h after RE (p=0.031). The groups were not significantly different from each other at any time point. Maximal Ca2+ uptake rate decreased after three bouts of RE in DM1 (p=0.01), while Ctrls were unchanged. The Ca2+ release rate was higher in DM1 compared to Ctrls after RE (p=0.04). DM1 showed lower p-PLB compared to Ctrls after RE (p=0.004). None of the other proteins investigated changed expression after RE.

CONCLUSION: DM1 had a higher Ca2+ uptake rate and a higher SR Ca2+ load at baseline compared to Ctrls. We speculate if p-PLB play a role in the different Ca2+ uptake rate between DM1 and Ctrls. The acute MVC reduction in DM1 indicate a slightly lower exercise tolerance compared to Ctrls, however DM1 still recovered after 24 hours. Interestingly three bouts of RE seem to have a normalizing effect on SR Ca2+ uptake rate in DM1 patients which could be explained by a reduction in p-PLB.

PHYSICAL FATIGUE FOLLOWS PERCEIVED RATHER THAN ACTUAL TIME

MATTA, P.M., BAURÈS, R., DUCLAY, J., ALAMIA, A.
UNIVERSITÉ TOULOUSE III – PAUL SABATIER

INTRODUCTION: The influence of the mind on physical performance has been extensively demonstrated in the last decades (1). In line with these findings, we highlighted in a previous study how unconsciously manipulating time perception significantly slowed down the accumulation of neuromuscular fatigue (2). Here, we move forward by addressing two important yet unresolved questions: 1) What are the neural correlates of this effect, and 2) Is this effect persistent in the absence of motivational confounds (i.e., performance goals)?

METHODS: 24 subjects participated in four separate sessions in which they performed 100 isometric knee extensions against a fixed resistance (20% of their maximal torque). While the rest time between contractions was identical (5s) for each session, each contractions real (R) and perceived (P) time were independently manipulated. In each session, the contractions' time was either short (10s) or long (12s), while the digital clock displayed in front of the participants was either Normal (N) or Biased (B). This led to 4 counterbalanced conditions: N10 (10s P, 10s R), N12 (12s P, 12s R), B10 (10s P, 12s R), B12 (12s P, 10s R).

Using electroencephalographic recordings, we measured power changes in motor (beta [13-31Hz]) and frontal (theta [4-8Hz], alpha [8-12Hz] and beta [13-31Hz]) areas over the 100 contractions. Simultaneously, the root mean square of the quadriceps electromyographic activity (EMG) was computed. For each measurement, we extracted the integral over all contractions. Finally, pre to post-exercise changes in the quadriceps Maximal Voluntary Torque (MVT) were assessed. Repeated measures ANOVAs and paired t-tests were performed using frequentist and Bayesian frameworks to evaluate both the difference and absence of difference between sessions.

RESULTS: Pre to post-MVT decrease was larger in N12 (-24.2±2.3%) compared to N10 (-20.3±1.7%), B10 (-21.5±1.8%), and B12 (-20.1±1.5%) ($p<.05$). Similarly, EMG increase over the 100 contractions was greater in N12 (187.8±13.1a.u.) compared to N10 (180.1±9.8a.u.), B10 (181.0±9.7a.u.), and B12 (182.3±12.4a.u.) ($p<.05$). Importantly, there was no difference between N10 and B10 for both MVT and EMG ($p>.05$, Bayes Factor (BF)<.3). Regarding the underlying neural correlates, no difference was observed between the sessions in beta power of the motor area ($p>.05$, BF<.3). At the same time, frontal power in theta and beta bands exhibits a significant difference between N10 and N12 ($p<.05$), but no difference ($p>.05$, BF<.3) between B10 and N10, and N12 and B12, respectively.

CONCLUSION: Our study shows a subjective time-dependent accumulation of physical fatigue irrespective of motivational factors. Interestingly, this effect is observed only when the clock is slowed down, suggesting that fatigue accumulation can be reduced but not accelerated. This effect is mediated by an oscillatory dynamic that follows subjective time in frontal but not motor areas.

EXACERBATING PAIN IMPAIRS CYCLING PERFORMANCE WITHOUT ALTERING CORTICOSPINAL EXCITABILITY AND INTRACORTICAL INHIBITION

ZHANG, J., MCCLEAN, Z.J., HONARVAR, N., MORGAN, S., MACINNIS, M.J., ABOODARDA, S.J.
UNIVERSITY OF CALGARY

INTRODUCTION: During high-intensity exercise, pain arises from the accumulation of metabolites (e.g., H+, K+) and increased intramuscular pressure (1). While the contribution of pain on impaired exercise performance is poorly understood, studies using experimental pain models have suggested that the increased inhibitory afferent feedback and augmented feedforward central drive can accelerate the achievement of the sensory tolerance limit to compromise performance (2). While prior studies have investigated the effect of experimental pain on isometric exercise tasks, little is known about corticomotor modulations to painful stimuli during ecological dynamic tasks such as cycling. Accordingly, this study aimed to examine the effect of experimental pain on corticospinal excitability, intracortical inhibition, and neuromuscular function during cycling.

METHODS: Nine healthy, adult participants (2 females) completed a counterweighted single-leg cycling ramp incremental test to obtain peak power output (PPO) followed by two experimental sessions wherein single-leg cycling at 60% of PPO was performed to task failure. Sessions were performed either without (CTRL) or with (PAIN) an experimental pain intervention consisted of a complete vascular occlusion of the contralateral resting leg combined with electrical stimulation of thigh muscles. To measure corticospinal excitability and intracortical inhibition, 2 femoral nerve stimuli, 5 unconditioned single-pulse transcranial magnetic stimuli (TMS), and 5 short- and 5 long-interval paired TMS pulses were elicited every five minutes during cycling to evoke Mmax, MEP, SICI, and LICI, respectively. Following each stimulation epoch, the bike pedals were locked and participants performed a brief maximal voluntary contraction (MVC) combined with femoral nerve stimuli to characterize neuromuscular function. Subjective ratings of leg pain, fatigue, and effort were also measured every 5 min.

RESULTS: Despite a shortened time to task failure in the PAIN condition (37±12min vs. 61±21min; P=0.015), no differences in neuromuscular function (i.e., MVC force, voluntary activation, and quadriceps twitch force) were present between conditions. Additionally, there were no between-condition differences in Mmax, MEP, SICI, or LICI during cycling (all P>0.05). Contralateral leg pain ratings were higher in PAIN than CTRL (P<0.001), but exercising leg pain was higher in CTRL than PAIN (P=0.015). No differences between fatigue or effort appeared between conditions.

CONCLUSION: Pain impaired exercise performance, but this impedance occurred independently from the intracortical, corticospinal, and neuromuscular pathways governing voluntary movement. Instead, regardless of the amount of inhibitory afferent feedback, exercise terminated once individuals achieved a maximal tolerable limit which was accelerated and primarily determined by perceived pain.

FATIGUE-INDUCED ALTERATIONS IN THE SPATIAL DISTRIBUTION OF LUMBAR ERECTOR SPINAE MUSCLE ACTIVITY IN OLDER VERSUS YOUNG ADULTS

PARRELLA, M., BORZUOLA, R.1, SICILIANO, F.P.1, ARVANITIDIS, M.2, NUCCIO, S.1, FALLA, D.2, PIACENTINI, M.F.1, MACALUSO, A.1

1 UNIVERSITY OF ROME FORO ITALICO; 2 UNIVERSITY OF BIRMINGHAM

INTRODUCTION: Fatigue resistance of the trunk extensor muscles is associated with mobility in older adults (1). However, the neuromuscular mechanisms associated with age-related changes in fatigue resistance of these muscles are unclear. When muscle fatigue occurs, changes in the spatial distribution of motor unit activity within a muscle or muscle group play a significant role in modulating motor output (2). This study aims to examine how ageing affects the spatial distribution of lumbar erector spinae (ES) activity during a fatiguing task. Preliminary findings are reported here and will be updated at the time of the congress.

METHODS: Fourteen volunteers, 7 older (O, age: 66±1) and 7 young (Y, age: 25±2), performed an isometric trunk extension at 30% of their maximal voluntary isometric force until failure. High-density surface electromyography signals were recorded using a 13x5 grid of electrodes placed over the lumbar ES. Mean power spectral frequency (MNF) was computed across the entire grid, and the x- and y-coordinates of the centre of gravity (CoG) of the root mean square (RMS) map were measured for the medial-lateral and cranial-caudal direction, respectively. Force steadiness was quantified using the coefficient of variation of force (CVf). A two-way mixed ANOVA was used to detect differences in MNF, CoG coordinates and the CVf over time (5 epochs of equal duration) and between groups. The Wilcoxon test was performed to compare endurance time between groups.

RESULTS: Endurance time did not differ between groups (Y: 85.80±48.60s; O: 81.00±39.60s) (p=0.90). MNF significantly decreased from the beginning to the end of the fatiguing task in both Y (p<0.01) and O (p<0.01). There was a significant time*group interaction for the x-coordinate of the CoG (p<0.01), indicating a shift of the CoG in the lateral direction in O, while the opposite was observed in Y, particularly for the last two epochs. A trend was observed for the y-coordinate (p=0.08) with O exhibiting a more caudal position of the CoG compared to Y. Lastly, CVf significantly increased at the end of the fatiguing task in both Y (p=0.01) and O (p=0.01).

CONCLUSION: Preliminary observations show comparable trunk extension endurance in older and young subjects together with a comparable decrease in MNF and an increase in CVf during the sustained task. However, the spatial distribution of ES activity differed between groups, suggesting a different motor control strategy to counteract fatigue of the ES with ageing. Likely, a different load sharing within the ES muscle occurs. However, this does not affect endurance time.

ACUTE CHANGES IN H-REFLEX AND V-WAVE FOLLOWING SINGLE AND CONCURRENT EXERCISE SESSIONS

GOMES, M., GONÇALVES, A., VILA-CHÃ, C., PEZARAT-CORREIA, P., MENDONCA, G.V.

FACULTY OF HUMAN KINETICS - UNIVERSITY OF LISBON

INTRODUCTION: Concurrent exercise (CE) combines resistance and aerobic exercise to enhance strength (S) and endurance (E). While short-term endurance training increases the H-reflex excitability, resistance training enhances V-wave amplitude, reflecting spinal and supraspinal adaptations, respectively (1). The acute impact of combining both stimuli on the aforementioned parameters remains largely unknown. This study explored H-reflex and V-wave acute changes following single and CE sessions completed in both orders (SE and ES)

METHODS: Ten healthy, trained males (22.8±2.5yrs) participated in this crossover-design study, with baseline assessments and four randomized exercise sessions (S,E,ES,SE). E sessions involved 30 min of treadmill running at a velocity 25%>1st ventilatory threshold, and S sessions included back squats with varied loads (40-90%1RM) and loaded/unloaded jumps. All CE sessions included a 20-min rest between modalities. Assessments of soleus evoked V-wave amplitude, H-reflex recruitment curves, maximal voluntary contraction (MVC) and rate of torque development (RTD) of the dominant limb plantar flexors were conducted at baseline and immediately after each session. Paired samples t-tests between baseline

and post-session evaluated the individual impact of each session, and a one-way repeated measures ANOVA assessed differences between session types. Significance was set at $p<0.05$

RESULTS: MVC and peak RTD of the plantar flexors significantly decreased in all sessions (-13.9 to -19.1% and -24.1 to -31.3%, respectively, $p<0.05$). RTD during the first milliseconds of contraction was unaffected, but subsequent epochs (50-150ms) showed a larger decline in all sessions, with significant differences between E (-40.2±17.5%) and S (-19.4±14.1%) ($p<0.05$). This was concomitant with similar declines in soleus electromyography amplitude across all sessions (-36 to -62%, $p<0.05$). No changes were observed in M-wave amplitude. The normalized V-wave amplitude decreased similarly after all sessions (-13 to -30%, $p<0.05$). Sessions incorporating E exercise reduced the maximum normalized H-reflex amplitude (-17.9 to -25.6%) with significant differences from S session ($p<0.05$). H-reflex excitability threshold remained unchanged, while the slope of the ascending limb of the recruitment curve significantly decreased after both CE sessions (-48.3 to -49.8%, $p<0.05$)

CONCLUSION: E exercise alone reduces the MVC and RTD of the plantar flexors, along with the neural drive to the active muscles. Such effects might compromise the quality of subsequent S sessions. Regardless of training sequence, CE acutely reduces the excitability of the H reflex, which suggests an acute impact on modulation at the spinal level. Ultimately, this indicates that altered H-reflex excitability may have an etiological role in the CE interference effect and this is novel.

PROFILING PACING AND UNDERLYING KINEMATICS DURING 400M FRONT-CRAWL WITH EMBEDDED SENSORS AND FUNCTIONAL MODELING OF LARGE DATABASE: HIGHLIGHTING THE TECHNICAL REGULATIONS OF VARIOUS PERFORMANCE LEVEL

BOUVET, A., NICOLAS, G., BIDEAU, N.
LABORATOIRE MOUVEMENT SPORT SANTÉ

INTRODUCTION: Monitoring of the 400m front-crawl test is of crucial interest to provide valuable feedback on performance and technique, driving construction of training plan and race strategy. Thus, some studies looked at pacing during this event but were limited to split times with narrow performance level [1], reduced sample size [2], and without technical considerations [3]. Then, there is a need for analyzing pacing and kinematics associated with performance at various levels, especially because speed management regarding individual stroke mechanics remains unclear. This study aimed at modeling kinematical features during 400m tests to profile functional patterns of pacing and technical regulations according to specific performance groups and the overall population.

METHODS: 123 trained to elite swimmers performed a 400m all-out in front-crawl with an Inertial Measurement Unit (Xsens DOT, The Netherlands) on the sacrum. Participants were divided into 4 balanced groups from lowest (G1) to best (G4) final time. Speed, stroke rate (SR), stroke length (SL) and jerk cost (JC) were computed by lap and fitted using hierarchical generalized additive models [4] to describe both the relationships between kinematics and performance and evaluate profiles of regulation across the laps. Fisher tests and visualizations of the functional responses were used for interpretations. Significance was set at $p<0.05$.

RESULTS: Significant relationships with performance displayed an inverse-sigmoïd shape for SL, with inflection points at 1.12 and 1.62 m/stroke, and a rising shape for JC with a deviation for G1. Kinematical profiles displayed significant regulations as reverse J-shape pacing with deviation for G1 that steeper this pattern, reverse J-shape and positive profile for respectively SR and SL functional response with both common opposite deviations for G1 and G4 that correspondingly mitigate and steeper the global regulation, U-shape for JC with deviation for G2 that mitigate the common profile, by opposition of G3 and G4 that steeped it with a higher extent for G4.

CONCLUSION: Useful technical benchmarks regarding the common and group-specific kinematical regulation across 400m on a large database were provided. Key points of global performance are a SL and a JC respectively higher to 1.25 m/stroke and 15 g^2/s^2x10-3, even if low intra-cyclic acceleration fluctuations is fundamental for improvement beyond G3. Preserving energy for finish, by the ability to lower the fast start and accentuate the end spurt is a determinant of progress. Such effective pacing involves typical kinematical regulations targeting to maintain stroke smoothness as much as possible, while displaying both opposite and major variations in SR and SL modulations. This framework allows to tailor and drive the development of race strategy by understanding and diagnosing the underlying technical requirements of successful pacing skills.

BOWLING ACTION TECHNIQUE DIFFERENCES BETWEEN ELITE & SUB-ELITE CRICKET FAST BOWLERS USING 3D BIOMECHANICAL ANALYSIS

RAMAN, S.A., NIMISHAANTH, S.S., ARUN, C., THIAGARAJAN, K.A., ARUMUGAM, S.
SRI RAMACHANDRA INSTITUTE OF HIGHER EDUCATION & RESEARCH

INTRODUCTION: Cricket fast bowlers utilise various techniques to help propel the ball faster, including some techniques which carry injury risk. Biomechanical studies have demonstrated technique related factors which can influence performance and injury risk. This study aims to evaluate technique differences between elite and sub elite fast bowlers, to understand the factors contributing to performance and injury risk.

METHODS: 15 male Indian elite and 15 sub elite fast bowlers underwent 3D biomechanical analysis of their bowling action in an indoor biomechanics lab. Front foot Peak Vertical Ground Reaction Force (pVGRF), Lateral Trunk Flexion (LTF), Knee Flexion at Front Foot Contact (KF at FFC), Maximum Knee Flexion (MKF) during front foot contact phase, Stride Length (SL), Ball Release Height (BRH) and ball speed were calculated. After tests for normality, the t-test (parametric method for normally distributed variables) & Mann Whitney U test (non-parametric method for variables not following normal distribution) were used to study differences among the groups.

RESULTS: Elite bowlers when compared to sub elite bowlers, had significantly higher mean pVGRF ($p=0.03$), SL ($p<0.001$), MKF ($p=0.02$), LTF ($p=0.008$), BRH ($p=0.02$) and ball speed ($p=0.019$). Mean KF at FFC showed no difference between the two groups ($p=0.85$).

CONCLUSION: Elite bowlers bowled with longer stride length and higher ball release height which could contribute to the greater bowling speeds. Elite bowlers demonstrated higher lateral trunk flexion and higher ground reaction forces which carries higher risk of lumbar spine injury. However, elite bowlers also had higher knee flexion during front foot contact phase, which could mitigate injury risk to some extent. These findings are important for injury prevention, however need to be considered along with other factors such as bowling workload, strength & conditioning status and spinal maturity.

PRELIMINARY STUDY ON THE DISTRIBUTION OF CONTACT FORCES OF A CLIMBER IN DIFFERENT TYPICAL POSITIONS

BONELLI, E., COLOMBO, A., RAMPICHINI, S., LIMONTA, E.
POLITECNICO DI MILANO

INTRODUCTION: Sport climbing is transitioning from a niche to a mainstream activity. Understanding of this sport's biomechanics is still fragmentary. We have developed sensors to measure the 3D contact force vectors between a climber and the climbing holds (1). Such an apparatus has been employed to characterize the kinetics of 2 typical positions at 3 different wall angle. In this preliminary data analysis we report the force distribution on 3 climbing holds.

METHODS: We recruited 16 climbers (8m, 8f, age 26±7yr, height 1.71±0.06m, body mass 66±9kg, right handed, climbing level >18 in IRCRA scale). One position was characterized by fully extended legs and flexed dominant arm (A), the other by bent legs and fully extended dominant arm (B). Climbers had feet on 2 holds 0.46m apart and right hand on a hold 1.44m or 1.62m above the footholds, depending on subject height. The 3 holds were identical 0.06m deep crimps. After familiarization, climbers alternated 10x10s repetitions of A and B, with 30s recovery time. This sequence was repeated at 3 wall angles: +5, 0, -5 degrees from vertical. The magnitudes of hand (FHand), right (FRfoot) and left (FLfoot) foot forces during A or B were normalized by body mass. The 2 positions and the 3 wall angles compose 6 scenarios: A+5/0/-5 and B+5/0/-5. For each triplet (scenario, subject, hold), we tested reliability (ICC>0.5) of the 10 measures. Unreliable triplets were excluded, the 10 measures of reliable triplets were averaged, then outlying triplets were removed (Matlab function robustcov). Average values for each triplet were then considered. We performed a Shapiro-Wilk test to check the distributions normality and a two-way RM-ANOVA (factor: position; level: wall angle; $\alpha=0.01$) to assess differences among scenarios.

RESULTS: Forces in the 6 scenarios are normally distributed, except for a slightly non-normal distribution for FHand in A0. FLfoot is independent of wall angle, and larger in A than in B (A-5: 0.55±0.04, A0: 0.55±0.04, A+5: 0.52±0.06, B-5: 0.34±0.03, B0: 0.34±0.03, B+5: 0.33±0.04). The difference FRfoot - FHand instead highlights a significant ($P<0.001$) load transfer as the wall angle transitions from -5 to +5 degrees in both positions (A-5: 0.43±0.03, A0: 0.29±0.04, A+5: 0.15±0.06, B-5: 0.02±0.09, B0: -0.05±0.09, B+5: -0.12±0.08). FLfoot appears higher than FRfoot in all scenarios (A-5: 0.12±0.07, A0: 0.16±0.08, A+5: 0.16±0.08, B-5: -0.01±0.06, B0: 0.01±0.06, B+5: 0.03±0.05).

CONCLUSION: In both positions, body kinematic adaptation to changing wall angle is predominantly homolateral, between the hand and the same-side foot. The load on the other foot is unaffected by wall angle. Load distribution is predominantly contralateral, as FLfoot is larger than FRfoot in all but one scenarios. These findings provide valuable bases to characterize climbing strategies and optimize training.

BIOMECHANICAL IMPACT: SPINAL ELONGATION AND SHRINKAGE IN GOLF PUTTING

UGBOLUE, U.
UNIVERSITY OF THE WEST OF SCOTLAND

INTRODUCTION: Putting constitutes nearly half of a golfers total strokes per round, demanding precision, accuracy, and control (1). Spinal overextension results in strains and sprains in supporting ligaments and muscles, while spinal compression, leading to issues like trapped nerves, occurs as the spine comes closer together (2; 3). The absence of studies using

motion capture systems creates uncertainty about the optimal method for measuring spinal changes during golf putting. Therefore, this study applied kinematic techniques to investigate how slope and distance constraints impact spinal elongation and shrinkage of the Lumbar and Thoracic regions during golf putting at 3ft and 7ft distances.

METHODS: Fifteen amateur golfers were selected to take part in testing within the biomechanics laboratory of the University of the West of Scotland. The fifteen participants performed three putts from three different slope constraints; Flat, Uphill and Downhill and two different distance constraints: 3ft and 7ft. Retroreflective markers were placed on the spinal processes from the cervical (C7) to lumbar (L5) spine. Four phases of the golf putting tasks were assessed (Address; Top of the Back Swing; Impact and Follow through). Vicon Motion Capture was used to collect data and process data on the movement of the thoracic and lumbar regions of the spine. Statistical analyses comprising of Shapiro-wilk tests, and a 3-Way ANOVA were applied to the distance constraint, slope constraint, spinal level datasets and their interactions. A one-way ANOVA was applied to the golf putting phases with respect to the changes in spinal movement at the spinal levels. Independent sample t-tests for distant constraints in relation to spinal phase were produced.

RESULTS: In terms of elongation and shrinkage of the spine, correct placement of retroreflective markers on the spinal processes was key in enabling successful tracking and measurements of the spinal processes and distances between the markers. Significant differences were found when comparing 3ft and 7ft distance constraints, all slope constraints, and spinal levels ($P < 0.05$, $F > 0.066$) at the Impact and Follow through phases with respect to the Address phase. However, no significant differences in spinal elongation / shrinkage were observed between Address and Top of the Back Swing for all distance constraints and spinal levels ($P < 0.05$).

CONCLUSION: The results offer valuable insights for golfers regarding spinal elongation and shrinkage. The study unveils a consistent trend of spinal compression in both lumbar and thoracic regions throughout various phases of the putting swing.

OP-AP17 Fatigue and recovery measurements

DEVELOPMENT AND EVALUATION OF A MULTIPARAMETER PREDICTION MODEL FOR RECOVERY AND STRESS MONITORING IN ELITE ICE HOCKEY: A LONGITUDINAL STUDY

EGGENBERGER, P., BUFFAT, N., WEBER, T., GUBLER, R., BRUNNER, E.

OST - EASTERN SWITZERLAND UNIVERSITY OF APPLIED SCIENCES

INTRODUCTION: Youth and adult athletes in high-level sports experience an elevated risk for injury and illness during phases of higher training and competitive load. When recovery is neglected under these circumstances, psychological and physical health problems might arise. These are referred to as nonfunctional overreaching or overtraining syndrome, OTS (1,2,3). OTS is characterized by athletic performance beeing reduced for more than 3-4 weeks up to months. Concurrent symptoms include mood and sleep disturbances, feelings of depression, respiratory tract infections, and weight loss, among others. This condition is highly prevalent, with 10-20% of young adult and about 29% of young athletes from various sports beeing affected (4). To our knowledge, no validated and reliable measurement system currently exists, that would allow for preventive, early diagnosis of overreaching states that might lead to OTS (5). The aim of this study is to develop and evaluate a multiparameter prediction model to assess the recovery and stress state of athletes.

METHODS: Twenty-five male ice hockey players from the highest level Swiss leagues, at their respective age groups, participated (i.e., National League, n = 11, age = 24.8+-4.1 years and U20, n = 14, age = 18.5+-1.5 years). Over 5 - 10 weeks during the in-season (i.e., competition phase) measurements were performed on 10 separate days, either after 1 day of recovery or after a day with match/intensive training. The test battery comprised 40 predictor variables from counter movement jump (CMJ), heart rate variability (HRV), executive function, tympanic temperature, weekly rating of perceived exertion, and sleep measurements. The Stress Recovery Short Scale (SRSS) served as reference variable. Least Absolute Shrinkage and Selection Operator (LASSO) regularized regression analysis was performed for variable selection, training, and cross-validation of a binomial prediction model.

RESULTS: Based on 163 timepoints of measurement, our developed LASSO regression model predicted SRSS scores < 5 (i.e., highly stressed state) with very good performance (area under curve, AUC = 0.921, sensitivity = 0.889, specificity = 0.843). The prediction model retained variables from all applied measurement methods, with HRV, CMJ, and sleep beeing represented among the 10 most important predictive variables.

CONCLUSION: Due to the multisystemic nature of overreaching and OTS states, we conclude that a multiparameter prediction model, containing relatively easily measurable parameters, might be most reliable and practicable for long-term monitoring in athletes.

WHAT IS THE DIFFERENCE BETWEEN CENTRAL AND PERIPHERAL RATINGS OF PERCEIVED EXERTION? A META-ANALYSIS

MACPHERSON, T., GRAHAM, M., MCLAREN, S., ATKINSON, G., WESTON, M.
NORTHUMBRIA UNIVERSITY

INTRODUCTION: Despite the potential of dRPE to provide a more precise appraisal of exercise exertion, questions exist of its usefulness and worthwhileness due to lack of differences between the two constructs. We aimed to quantify the magnitude of the difference between RPE-P and RPE-C (P–Cdifference) and to explore the moderating influence of methodological factors that could impact P–Cdifference.

METHODS: In accordance with PRISMA guidelines. we searched five academic databases for original research articles published up to October 2023 and available in English. A Boolean search phrase was created to include search terms relevant to internal load / ratings of perceived exertion (19 keywords), dRPE (20 keywords) and exercise/ training sessions (60 keywords). We obtained the mean difference between peripheral and central RPE, as well as the standard deviation of the difference, by extracting individual data and calculating the mean difference in ratings manually (i.e. peripheral exertion score minus central exertion score), allowing dominance between the two perceptual ratings to be assessed. The final data sample included 94 datasets, from 70 individual studies and included 2167 participants from a mixture of activity levels. Random effects meta-analyses were conducted on each dataset to determine the extent of the P–Cdifference. To explore moderator effects of the P–Cdifference, we utilised subgroup comparison analysis when two of more studies were available for analysis. The categorical moderators that we used were study population, exercise modality and whether familiarisation was reported in the study. Magnitude-based decisions provided interpretation of the P–Cdifference in relation to a threshold of 10% of the mean dRPE scores (0.6 arbitrary units [au]). A P–Cdifference was only declared clear if the probability for the difference was ≥ 95% (i.e., very likely).

RESULTS: Random effects meta-analysis revealed no clear rating dominance between RPE-P and RPE-C (0.6 Category–Ratio 10 arbitrary units [au]; 95%CI: 0.4 to 0.7). Moderator analysis showed study population explained 27% of the variance in the P–Cdifference ($\tau = 0.76$, $r^2 = 0.27$), with RPE-P clearly dominant in disabled (1.3 au; 95%CI 0.7 to 1.8 au) and normal/ healthy (0.9 au; 95%CI 0.5 to 1.3 au) participants when compared to RPE-C. Exercise mode explained 13% of the heterogeneity of the P–Cdifference ($\tau = 0.76$, $r^2 = 0.13$), with RPE-P clearly dominating during arm crank (2.1 au; 95%CI 1.4 to 2.8 au) and cycling (0.8 au; 95%CI 0.5 to 1.1 au) exercise when compared to RPE-C. Familiarisation failed to explain the heterogeneity of the P–Cdifference ($\tau = 0.76$, $r^2 = 0.00$), although when studies reported habituation to RPE procedures, RPE-P was dominant (0.8 au; 95%CI 0.6 to 1.0 au).

CONCLUSION: We found the pooled effect to show no clear dominance for either RPE-P or RPE-C but our moderator analysis helped to explain the variance in P–Cdifference and thus supporting dRPE to be sensitive in detecting methodological changes.

RESPIRATORY AND MUSCULAR PERCEIVED EXERTIONS IN YOUNG FEMALE FOOTBALLERS

GONZALEZ-ARTETXE, A., ESNAL-ARRIZABALAGA, O., GARCÍA-TABAR, I., LOMBARDERO, S., LOS ARCOS, A.
FACULTY OF EDUCATION AND SPORT, UNIVERSITY OF THE BASQUE COUNTRY, UPV/EHU

INTRODUCTION: The rating of perceived exertion (PE) provides a simple, non-invasive, no-cost, and valid method for assessing internal workload of the training sessions (1). Since this gestalt could represent an oversimplification of the psychophysiological construct (2), several studies suggested the deconstruction of PE to assess training related perceptual sensations in male footballers (3,4). Respiratory and muscular PEs (i.e., PEres and PEmus) were recently assessed in female football (5,6). However, the differences between PEres and PEmus within and between training sessions remained unclear in female players (6). It was therefore deemed necessary to further clarify and analyse the quantification of the perceived training load differentiating between PEres and PEmus in female young footballers.

METHODS: Sixteen female trained footballers (age: 17 ± 1 years; range: 15 to 21) belonging to the third team of a Spanish first-division club declared their PEres and PEmus after each training session (3,4) during seven weeks of the in-season competitive period. They performed three training sessions during the habitual week: I) Tuesday: football specific training, II) Thursday: strength and football specific training, and III) Friday: football specific training. Only the players that completed all training sessions were considered.

RESULTS: Observations registered were 104 per each type of training, and 5-7 per player in each type of training. Players declared greater PEres than PEmus for all type of trainings: I) Tuesday (PEres: 4.94 ± 0.82, PEmus: 3.64 ± 0.79; $p < .001$, Cohen's d = 1.21), II) Thursday (PEres: 4.13 ± 0.76, PEmus: 3.52 ± 1.12; $p = .031$, Cohen's d = 0.60), and III) Friday (PEres: 3.63 ± 0.69, PEmus: 2.90 ± 0.54; $p = .003$; Cohen's d = 0.89). Players declared greater PEres after Tuesday training in comparison to Thursday ($p < .001$, Cohen's d = 1.36) and Friday ($p < .001$, Cohen's d = 1.82), and after Thursday in comparison to Friday ($p = .005$, Cohen's d = 0.83). Players declared greater PEmus after Tuesday ($p = .002$; Cohen's d = 0.95) and Thurs-

day (p = .021; Cohen's d = 0.65) trainings in comparison to Friday, but significant differences were not found between Tuesday and Thursday sessions (p = .540; Cohen's d = 0.16).

CONCLUSION: Training PEres was always greater than PEmus, being the differences higher for the hardest training session. This suggests that the deconstruction of PE provides additional information about the female footballers' internal workload. These outcomes are of interest for the strength and conditioning staff to adjust conditional specific contents, especially strength exercises, during the training week in this population. Furthermore, the internal workload decreased as the match got closer.

HEART RATE VARIABILITY IN REGULAR SEASON AND PLAY-OFF COMPETITIONS IN PROFESSIONAL ARCHERS

YUAN, S.C., HUANG, Y.F., CHANG, C.K.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: Archery is a precision close-circuit sport. Archers have to adjust their arousal level under competition pressure for optimal performance. Heart rate variability (HRV) represents the balance between autonomic nervous system. The purpose of this study is to investigate heart rate variability before and during regular-season and play-off competitions in professional archers.

METHODS: Four male and four female archers from a professional team in Chinese Enterprise Archery League were recruited. The participants wore a portable HRV device (Largan Health AI-tech, Taichung, Taiwan) before and during League competitions from April to October, 2023. HRV data during the 30-min period before the competitions (B) and the 15-min period during the competitions (D) were analyzed. Overall, 12 regular season (RE) and 6 play-off (PO) competitions were included.

RESULTS: During RE competitions, heart rate (HR) was significantly increased from before competition (B:95.37±11.59; D:110.11±15.51 bpm, p<0.001) while low-frequency power (LF) (B:43571.5±20867.0; D:19203.6±12634.7, p<0.001), high-frequency power (HF) (B:9733.2±6478.1; D:5403.6±3900.3, p<0.001), and LF/HF ratio (B:5.50±2.67; D:4.50±2.92, p=0.020) were significantly decreased. During PO competitions, HR was significantly increased from before competition (B:99.44±11.14; D:111.62±15.01 bpm, p<0.001) while LF (B:37288.0±23012.8; D:15819.7±10135.6, p=0.000), HF (B:8691.3±7340.9; D:4280.0±3831.6, p<0.001) were significantly decreased. Pre-competition HR was significantly higher in PO than RE (RE:95.37±11.59; PO:99.44±11.14 bpm, p=0.040) while root mean square of successive differences between normal heartbeats (RMSSD) (RE:66.65±26.95; PO:56.27±28.74, p=0.031) and standard deviation of the normal-normal interval (SDNN) (RE:82.87±19.68; PO:74.14±22.25, p=0.016) were significantly decreased. During-competition rMSSD (RE:63.41±28.04; PO:53.43±26.45, p=0.036) SDNN (RE:79.25±19.16; PO:71.09±21.11, p=0.019) were significantly lower in PO than RE.

CONCLUSION: The results showed that professional archers had a significant increase in heart rate and a noticeable decrease in sympathetic and parasympathetic nervous system activity during RE and PO competitions. It suggested that professional archers perceived higher tension and stress even though they tried to suppress arousal. The lack of difference in LF/HF before and during PO competitions indicated that the participants experienced higher stress and pressure The participants exhibited a significant decrease in relaxation level and autonomic nervous system activity in PO compared to regular season matches, experienced higher stress and pressure, possibly due to the close association with final rankings. Individualized stress adaptation training may be necessary for these group of elite archers for optimal performance in competitions.

ADEQUATE RECOVERY DAYS BETWEEN SOCCER MATCHES FOR FEMALE SOCCER PLAYERS

CHEN, T.C.1, CHOU, T.Y.1, NOSAKA, K.2

1. NATIONAL TAIWAN NORMAL UNIVERSITY, TAIPEI, TAIWAN; 2. EDITH COWAN UNIVERSITY, JOONDALUP, WA, AUSTRALIA

INTRODUCTION: Our previous study [Chou et al. Int J Environ Res Public Health. 2021;18:4134] showed that muscle damage and performance measures took 4-5 days for female soccer players to return to the baseline following a 90-min Loughborough Intermittent Shuttle Test (LIST) that mimics running activities in a soccer match. The study also found that the total distance covered in the LIST was 5-7% shorter for the second to sixth LISTs than the first LIST when the LIST was performed 6 consecutive days, and decreases in muscle strength and other performance measures were still evident at 5 days after the sixth LIST [Chou et al. 2021]. No study has investigated how many days are necessary between matches for good performance with minimum muscle damage, thus the present study compared four different intervals between three LISTs for changes in muscle damage and performance parameters.

METHODS: Thirteen well-trained female university soccer players performed three bouts of 90-min (15-min x 6 sets with 3-min between sets) LIST with four different intervals between bouts; one (1d), two (2d), three (3d) and four days (4d), with more than 12 weeks between bouts in a counterbalanced order. Heart rate (HR), blood lactate (LA), rating of perceived exertion (RPE) and distance covered in each LIST were measured. Changes in several muscle damage markers [maximal voluntary isometric torque of the knee extensors (MVC-KE) and flexors, muscle soreness, plasma creatine kinase activity and myoglobin concentration], and performance parameters [countermovement jump, 30-m sprint, 30-m timed hop test, agility T-test, 6x10-m shuttle run, Yo-Yo intermittent recovery test level 1 (YYIR1)] before the first LIST, 1 hour after each LIST, and 1-5 days after the third LIST were compared among the conditions by a two-way of repeated-measures ANOVA.

RESULTS: The total distance covered in the first two LISTs (10,268±412m) was not different among the conditions, but that was 6-9% ($P<0.05$) shorter in the third LIST for the 1d and 2d conditions than the 3d and 4d conditions. HR, RPE and LA concentration in the three LISTs were not different ($P>0.05$) among the conditions. Changes in all measures were smaller ($P<0.05$) in the 3d and 4d conditions (e.g., the decrease in MVC-KE at 1 day after the third LIST was -13±4% and -10±3%, respectively) when compared with the 1d and 2d conditions (-20±7%, -18±5%). Performance parameters showed smaller ($P<0.05$) changes in the 4d (e.g., the decrease in YYIR1 at 1 day after the third LIST was -9±3%) and 3d (-13±6%) conditions when compared with the 1d (-19±4%) and 2d (-20±8%) conditions.

CONCLUSION: These results suggest that muscle damage and fatigue accumulate when LIST was performed three consecutive days or every other day, but if more than three days were inserted between matches, this could be minimized. However, even for the 4 days interval, some extent of muscle damage is inevitable, which possibly taxes the body for several days.

OP-AP13 Basketball Training

QUANTIFYING THE EXTERNAL TRAINING LOADS OF HIGHLY TRAINED MALE YOUTH BASKETBALL PLAYERS BY YEAR, TERM AND POSITION

FULLAGAR, H., LEVER, J., DUFFIELD, R., MURRAY, A., BARTLETT, J.
REYKJAVIK UNIVERSITY

INTRODUCTION: Current insights on the training demands within highly trained youth basketball academies are limited. Specifically, there remains a lack of detail on the specific physical demands and how they may differ between training blocks or playing positions. Therefore, this study aimed to describe the external training load of highly-trained male youth basketball players, based on training year, term, and playing position.

METHODS: Data was collected from 41 male youth basketballers (age = 17.4±0.9 years, height = 203.2±8.3 cm, mass = 91.2±13.3 kg) over two academy seasons from all on-court coach-led training sessions using a commercially available Local Positioning System. The academy provides a fulltime residential basketball development program alongside academic commitments. Linear mixed-models and pairwise comparisons were used to analyse by training year (Y1, Y2, Y3), term (T1, T2, T3, T4) and playing position (Backcourt, Frontcourt) for a variety of external load metrics, with significance set at $p \leq 0.05$.

RESULTS: Results showed no differences in external load metrics between training years. Significant differences existed between training terms, with total distance greater in both T3 and T4 than T1 and 2 ($p<0.03$). Total PlayerLoad was significantly greater in T4 than T1 ($p<0.001$) and 3 ($p=0.004$). Distance/min was greater in T2, T3 and T4 than T1 ($p<0.01$). PlayerLoad/min was higher in T4 than T1 and T2 ($p<0.01$). Backcourt players showed significantly greater distance/min ($p=0.011$), PlayerLoad/min ($p=0.011$) and deceleration counts ($p<0.001$). Overall, limited year-on-year change existed in external training load metrics ($p>0.05$), though volume ($p<0.001$) and intensity ($p<0.001$) differed between terms. Backcourt players completed higher-intensities ($p=0.011$) than Frontcourt players.

CONCLUSION: The results of this study show limited changes in training volume and intensity between years. However, within-season analysis by training term showed significant differences for most training load metrics, indicating a seasonal periodisation of training. Overall, this suggests that this academy environment implements a structured training program within the year, likely related to maximising skill development training. Collectively, this study provides contemporary reference points for practitioners for the external training loads experienced within youth basketball development pathways.

LONG-RANGE SHOTS IN 3X3 BASKETBALL: A COMPARISON OF CATCH-AND-SHOOT AND PULL-UP SHOTS

MADARAME, H.
SHIGAKKAN UNIVERSITY

INTRODUCTION: Making long-range shots from outside the arc is crucial to winning a game in 3x3 basketball because it results in twice as many points as a shot attempted from inside the arc. In traditional 5-on-5 basketball, it has been prevalent for about a decade to assess the performance of long-range shots by classifying the shots into two types, catch-and-shoot (CS) or pull-up (PU), depending on the process from the time the shooter receives the ball to its release. While stud-

ies analyzing shooting performance in 3x3 basketball are increasing [1-3], no studies have analyzed long-range shots in 3x3 basketball by classifying them into CS or PU. Therefore, this study aimed to investigate the proportion and success rates of CS and PU in 3x3 basketball games for men and women.

METHODS: The number of successful and unsuccessful shots attempted from outside the arc were recorded separately for CS and PU while watching videos of 191 games from the 2019 3x3 World Cup. Chi-square tests were used to 1) compare the proportion of CS and PU attempts between men's and women's games, 2) compare the success rates of CS and PU respectively between men's and women's games, and 3) compare the success rates of CS and PU within the same sex. The significance level was maintained at 5% by the Benjamini & Hochberg method.

RESULTS: The number of CS attempts exceeded the number of PU attempts in both men's (717 vs. 478 [60.0% vs. 40.0%]) and women's (586 vs. 372 [61.2% vs 38.8%]) games, with no sex difference in the proportion of CS and PU attempts (P = 0.61). While there was no sex difference in CS success rates (24.4% vs. 24.2%; P = 0.94), PU success rates were significantly higher in men's (27.2%) than in women's (17.7%) games (P = 0.005; effect size = 0.11). When success rates were compared within the same sex, there was no difference between CS (24.4%) and PU (27.2%) success rates in men's games (P = 0.37), but the CS success rate (24.2%) was significantly higher than the PU success rate (17.7%) in women's games (P = 0.04; effect size = 0.08).

CONCLUSION: Analysis of long-range shots separately for CS and PU showed no difference in the proportion of attempts between men's and women's 3x3 games, but there was a difference in the success rate between men's and women's 3x3 games. The results suggest the need for sex-specific training and tactics in 3x3 basketball.

POSITION DIFFERENCES OF LOWER EXTREMITY STIFFNESS IN WOMENS CHINESE BASKETBALL ASSOCIATION (WCBA) COMPETITION ATHLETES

WANG, D., WANG, Z., YANG, M., QU, K., MAO, X., YANG, X., ZHANG, Z., FANG, W.
SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: Lower extremity injuries (ankle and knee) are most common in basketball. With the increasing participation of women in sports, including basketball, concerns about the risks of sports injuries and their influence on performance have been raised. Womens Chinese Basketball Association (WCBA) competition is the highest level of women's basketball competition in China. Injury prevention is a vital component for good performance. Stiffness pertains to both injury and performance, which represents the capacity of mechanical and neurophysiologic mechanism integration to prevent injury and improve performance. Basketball players can be classified by position as forwards, centres and guards. Each position was characterized by its risk of injury and specific exercise pattern. It was expected that a difference in stiffness characteristics among basketball players based on position.

METHODS: A total of 124 participants were recruited for this study, including 63 forwards, 22 centres and 39 guards. Stiffness was evaluated in the pre-game and in-game phases of the 2020-2021 WCBA season. Quasi-static stiffness measurements of muscles and tendons were collected via a handheld myometer (Myoton AS, Tallinn, Estonia) on seven sites of each leg (lateral gastrocnemius, medial gastrocnemius, soleus, Achilles tendon, biceps femoris, rectus femoris, and patellar tendon). Vertical stiffness was evaluated through vertical hop (sing leg) and drop jump (both legs) test with OptoGait optical detection system (MicroGate Corporation, Bolzano, Italy) .

RESULTS: The Kruskal-Wallis test and post hoc Bonferroni pairwise comparisons found significant differences in stiffness of the left patellar tendon (PT) in guards than centres (p = 0.004) and in guards than forwards (p = 0.012), right PT stiffness in guards than centres (p = 0.016) and in guards than forwards (p = 0.017), mean PT stiffness in guards than centres (p = 0.003) and in guards than forwards (p = 0.008); stiffness of the right soleus (SOL) in guards than forwards (p = 0.033), stiffness of the left biceps femoris (BF) in centres than forwards (p = 0.049) and in centres and guards (p = 0.038); and stiffness of the left vertical stiffness (hopping) in forwards than centres (p = 0.041).

CONCLUSION: Forwards, centres and guards were characterized by significantly different stiffness values. This might provide basketball coaches with information on lower extremity stiffness at different positions, which could be utilised for athletic performance enhancement and injury prevention.

THE COMPETITION LOAD AND SPORTS PERFORMANCE CHARACTERISTICS OF ELITE WOMEN'S 3X3 BASKETBALL TEAM

LI, D., WANG, L.
CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: The 3x3 basketball is an emerging Olympic sport, but there are relevant few sport science and sport performance research on it. This study aim to analyze the game load and performance characteristics of the Chinese womens 3x3 basketball team in 7 matches of the "2019 3x3 Womans Series (3WS)" and 15 matches of the" 2021Olympic Test Matches (OTM)" in Shanghai.

METHODS: This study subjects consisted 9 athletes from the Chinese womens 3x3 basketball team(5 guards and 4 centers; average age: 24.1±3.8 years; average height: 180.4±8.8cm; average weight: 78.2±10.9kg). We used the Global Positioning System(GPS) "CATAPULT"(Catapult Group International Ltd,Australia) and "Polar team pro" (Finland, Polar Electro Oy) sensors to collect and analyze internal and external loads. The Lactate Scout (Germany, Senslab GmbH) was used to

test blood lactate (mmol.L-1) to analyze the internal load stress. The significance of differences with * indicating P<0.05 and ** indicating P<0.01.

RESULTS: 1) The 3WS averaged duration time was 1754"±41", match density was 53%, the OTM averaged duration time was 1634"±342", and match density was 59%.

2) The 3WS Playload™ and Playload™min were measured at 132.86±18.36a.u, 7.43±0.59a.u**↑. The OTM Playload™ and Playload™min were measured at 120.53±25.31a.u**↓, 7.19±0.48a.u**↑.

3) The 3WS explosive movements was 27±7.46times**↑, the OTM explosive movements was 23±9.1times**↑.

4) The 3WS average movement changes was 1080±163 times(excluding jumping). Among acceleration:139.5±12.5; deceleration:138±28; changes of direction(COD)-Left: 390±105; COD-right: 354.5±116.5; the number of COD-left and COD-right was almost 2.8 times higher than the number of acceleration and deceleration.

5) The OTM maximum HR 185±14.5bpm, average HR 155±12bpm. The distribution of zones follows: Zone-1: 15.4%,Zone-2:12%,Zone-3: 22.6%, Zone-4: 43.4%, Zone-5: 13.4%.

The 3WS maximum HR 200±25bpm**, average HR 168±19bpm**. The distribution of zones follows: Zone-1: 0%**, Zone-2: 8.0%**, Zone-3:17.5%**, Zone-4:29%**, Zone-5:47.5**.

6) The 3WS blood lactate were measured at 6.97±2.8 mmol·L-1 after 2 minutes, and 4.84±1.8mmol·L-1 after 10 minutes. The OTM blood lactate were measured at 6.86±1.05 mmol·L-1 after 2 minutes, and 4.10±0.65 mmol·L-1 after10 minutes.

CONCLUSION: In elite Womens 3x3 basketball, the Playload™min has significant increased. The main factors contributing to the increase of explosive movements and acceleration, deceleration, COD-left and COD-right(>3.5m/s). The 3x3 basketball not only is the proportion of anaerobic and glycolytic energy systems significantly higher than 5x5 basketball, but aerobic recovery capacity is also crucial. It requires higher levels of power endurance, and speed agility from players. If players participate in both 3x3 and 5x5 basketball games simultaneously, there is a higher risk of injury, so caution should be exercised.

INDIVIDUAL CUMULATIVE MATCH LOADS IN THE LIQUI MOLY HANDBALL BUNDESLIGA OVER AN ENTIRE SEASON

BAUMGART, C., HOPPE, M.W., SAAL, C.

UNIVERSITY OF WUPPERTAL

INTRODUCTION: For training control and injury prevention, knowledge of the individual match loads is essential. However, in elite handball, these loads have not been adequately described using quantitative measurements. The aim of this study was to quantify the cumulative match loads in the LIQUI MOLY Handball Bundesliga (HBL) over an entire season.

METHODS: The match loads of two men's handball teams were recorded during each competitive match of the season 2021/2022 (a total of 66 matches) using a validated radio-based positioning system (Kinexon Perform LPS, Kinexon GmbH, Munich). Match loads were operationalized based on the number of completed matches, playing time, total distance covered as well as the number of sprints, jumps, shots on goal, passes, and impacts. For validity reasons, only players with at least six match appearances (a total of 30 players) were considered. Quantiles of cumulative match loads (Q) were used for statistical analysis.

RESULTS: On average (Q50), 27.5 matches are played per season (Q0 = 9; Q25 = 20; Q75 = 30; Q100 = 32), corresponding to an average cumulative playing time (Q50) of 12 hours (Q0 = 1; Q25 = 7; Q75 = 19; Q100 = 26). The average cumulative values over the entire season are as follows:

- Total distance covered: Q50 = 56.9 km (Q0 = 4.9; Q25 = 35.1; Q75 = 90.3; Q100 = 134.5)
- Number of sprints: Q50 = 77 (Q0 = 8; Q25 = 47; Q75 = 150; Q100 = 912)
- Jumps: Q50 = 256 (Q0 = 10; Q25 = 120; Q75 = 393; Q100 = 960)
- Shots on goal: Q50 = 107 (Q0 = 6; Q25 = 49; Q75 = 148; Q100 = 244)
- Passes: Q50 = 1,137 (Q0 = 74; Q25 = 512; Q75 = 2,360; Q100 = 5,319)
- Impacts: Q50 = 216 (Q0 = 10; Q25 = 69; Q75 = 399; Q100 = 519)

CONCLUSION: The cumulative match loads in the HBL demonstrate significant inter-individual variation. In both teams, there are some players who suffer very high loads at the end of the season. These results can be attributed, among other factors, to the varying demands of different playing positions and the effective playing time of regular players. Further studies are necessary to transfer these findings into the practice of elite handball.

OP-PN30 Physiology/Mixed Session I

O2 DIFFUSION LIMITS OXIDATIVE CAPACITY IN YOUNG AND MIDDLE-AGE, BUT NOT IN ELDERLY MUSCLE

PILOTTO, A., ADAMI, A., ANSALDO, M., LAURETANI, F., RE, R., BOTTER, A., FRANCHI, M.V., BOTTINELLI, R., ROSSITER, H.B., PORCELLI, S.

UNIVERSITY OF PAVIA

INTRODUCTION: Aging leads to significant decrease in aerobic capacity, cardiovascular function (1), muscle strength and power, muscle mitochondrial oxidative capacity and capillarity (2). In older people, muscle fiber atrophy and loss of fiber oxidative capacity (3,4) may counter effect muscle capillary rarefaction (4) and thereby protect O2 diffusive flow into contracting muscle fibers by increasing the capillary supply region (5). We aimed to evaluate age-related differences in muscle oxidative capacity and O2 diffusion in vivo.

METHODS: Twelve young (YG; 26±5 y), nine middle-aged (MID; 57±5 y) and twelve old (OLD; 78±5 y) individuals volunteered. They underwent an incremental cycle-ergometry to the limit of tolerance for peak oxygen uptake (VO2peak). In a different occasion vastus lateralis VO2 recovery rate constant (k) was measured by near-infrared spectroscopy during repeated transient occlusions after moderate exercise. Duration and timing of occlusions were manipulated to keep tissue saturation index (TSI) within 10% bounds of two different O2 availability conditions: not-limiting (HIGH) and limiting (LOW) (6). kHIGH provides an estimate of muscle oxidative capacity, while the difference between kHIGH and kLOW (Δk) is inversely proportional to capillarity (a high Δk reveals O2 diffusion limitation). One-way ANOVA with Tuckey's post hoc test was used to test differences among groups and one sample t test was used to test Δk difference from zero in each group. Linear regression was utilized to analyze correlation of VO2peak with kHIGH and Δk.

RESULTS: YG had greater VO2peak than MID and OLD (35.7±8.2 vs. 30.1±5.6 and 24.2±4.4 ml*min-1*kg-1 respectively; $p<0.05$). kHIGH was greater in YG (2.97±0.55 min-1) compared to MID (2.09±0.63 min-1, $p<0.05$) and OLD (2.04±0.57 min-1, $p<0.01$), but MID and OLD were not different ($p=0.985$). Δk was significantly greater than zero ($p<0.05$) in YG (1.32±0.70 min-1) and MID (0.62±0.62 min-1), but not in OLD (0.02±0.65 min-1; $p=0.941$). Linear regression showed VO2peak significantly correlated with both kHIGH ($r=0.40$; $p<0.05$) and Δk ($r=0.38$; $p<0.05$).

CONCLUSION: Age-related differences in maximal aerobic capacity were related to skeletal muscle oxidative capacity and O2 diffusion limitation. Unlike young and middle-aged muscle, diffusive capacity was not limiting to muscle oxidative capacity in the elderly. Thus, our data suggest age-related muscle adaptations help to protect muscle oxidative function in older aging. Future analyses on muscle samples to better characterize muscle structure and function will help to gain insights into age-related differences in limitations to intramuscular O2 flow.

TEMPORAL RECOVERY DYNAMICS OF PERCEIVED COGNITIVE FATIGUE AND PREFRONTAL CORTEX OXYGENATION AFTER A SUSTAINED COGNITIVE ACTIVITY

GUBE, M., BEHRENS, M., WEIPPERT, M., BRUHN, S.

UNIVERSITY OF ROSTOCK

INTRODUCTION: Performing sustained cognitive activities (SCA) can lead to perceived cognitive fatigue as well as changes in motivation, affective valence, arousal, as well as boredom and has been shown to impair endurance performance and motor control during various tasks. However, the temporal recovery dynamics of the perceptual responses and oxygenation of the prefrontal cortex after SCA have rarely been studied. For this reason, temporal recovery dynamics of perceived cognitive fatigue and other perceptual responses as well as prefrontal cortex oxygenation were investigated for 60 min after an SCA

METHODS: In a randomised, counterbalanced cross-over design, 30 subjects (females: 15; age: 23 ± 2.9 years; BMI: 20.5 ± 3.1 kg*m-2) completed an SCA task (60min digital Stroop task) and a control task (60 min watching a neutral video). Thereafter, a neutral video was watched for 60 min in both conditions to monitor temporal recovery of variables. Development and recovery of perceived cognitive fatigue and other perceptual responses (e.g., motivation, affective valence, arousal, boredom) during and after SCA were assessed at regular time intervals with visual analogue scales. Furthermore, oxygenation of the prefrontal cortex was measured using functional near-infrared spectroscopy (fNIRS). Data were analysed using repeated measures ANOVAs.

RESULTS: No significant interactions of time x condition were observed for perceived cognitive fatigue ($p = .834$; $\eta p2 = .013$), motivation ($p = .132$; $\eta p2 = .061$), affective valence ($p = .397$; $\eta p2 = .035$), arousal ($p = .397$; $\eta p2 = .035$), boredom (p

= .894; ηp2 = .010). For oxygenation of the prefrontal cortex, trends for interactions were found (O2Hb; HHb; tHb; TSI%: p ≥ 0.093; ηp2 ≤ .064). No main effects of condition were shown for all parameters. No time effects were found for perceived cognitive fatigue as well as all other perceptual responses. Time effects were found for O2Hb, tHb and TSI% (p ≤ .011; ηp2 ≥ .100) but not for HHb (p = .096; ηp2 = .064).

CONCLUSION: Although no interaction effects were found for the perceptual responses, it appears that the initial level of prefrontal cortex oxygenation (baseline TSI%) is not achieved until 30 min after the SCA, while a full recovery was observed already during the first minute of recovery after the control task. These results indicate distinct temporal recovery dynamics of prefrontal cortex oxygenation but not the perceptual responses and emphasise the need for a multiparametric assessment to explain potential effects of SCA on subsequent cognitive or motor performance.

SKELETAL MUSCLE FIBER COMPOSITION AND BLOOD PRESSURE AFTER ACUTE AEROBIC EXERCISES

YLINEN, V., VALTONEN, R.I.P., STENBÄCK, V., MÄKELÄ, K., HERZIG, K.H., NÄPÄNKANGAS, J., JUNTTILA, J., TULPPO, M.
UNIVERSITY OF OULU

INTRODUCTION: The inter-individual responses vary from no change to marked reduction in blood pressure (BP) after an acute and chronic aerobic exercise. The physiological background for heterogeneity in BP responses after chronic or acute aerobic exercise is not known. We hypothesized that skeletal muscle fiber type may modify BP responses after an acute aerobic exercise.

METHODS: Normotensive participants (12 males and 8 females, age 27±6, maximal oxygen uptake 45±7 ml/kg/min) performed two 30 min aerobic exercises, continuous and interval intensities, by bicycle ergometer on separate days with BP measurements before and 60 min after exercises. BP was measured three times at baseline and 5 min intervals after exercises. Area under the curve after exercises (AUC) was calculated for systolic BP. Continuous aerobic exercise was 30 min at intensity of 60% of maximal exercise capacity. Aerobic interval exercise consisted of 8 x 1 min high intensity intervals (80-90% of maximal exercise capacity) with two min easy cycling between the intervals. The average workload was equal for both exercises (60% of maximal exercise capacity). Muscle biopsy was taken from vastus lateralis on separate day and the proportion of fast and slow fibers was counted.

RESULTS: The average proportion of fast type fibers was 55±17% (range 16-84%). The change in systolic BP from baseline to 60 min recovery phase was -9±10 mmHg (range -18 - +8) and -9±8 mmHg (range -10 to +3) in continuous and interval exercises, respectively (time p<0.001, group p=ns, time·group interaction p=ns). AUC for systolic BP was -386±387 mmHg·min (range -591 - +348) and -399±228 mmHg·min (range -347 - +183) after continuous and interval exercises (p=ns), respectively. The change in systolic BP from baseline to 60 min recovery and the AUC for systolic BP were correlated with the proportion of fast muscle fibers after interval exercise (r=-0.53, p=0.023 and r=-0.59, p=0.010, respectively) but not after continuous exercise (r=-0.20, p=0.42 and r=-0.19, p=0.45, respectively).

CONCLUSION: Inter-individual differences in post exercise BP responses are associated with skeletal muscle phenotype particularly after interval exercise. Participants with large amount of fast muscle fibers result in superior BP response after interval exercise compared to subjects with a low number of fast muscle fibers.

JOINT EFFECTS OF EXERCISE AND FASTING ON TELOMERE LENGTH: IMPLICATIONS FOR CELLULAR AGING

SELLAMI, M., ALMURAIKHY, A., ELRAYESS, M.
QATAR UNIVERSITY

INTRODUCTION: Aging is a fundamental biological process that progressively impairs the functionality of the bodily systems, leading to increased risk of diseases. Telomere length is one of the best biomarkers of aging. Recent research has focused on developing interventions to mitigate the effects of aging and improve the quality of life.

Some of these strategies are diet and exercise. Intermittent fasting is often used to manage weight and metabolic health. Similarly, aerobic exercise is considered an effective strategy to enhance longevity and health span via its multi-system anti-aging effects. Elite athletes usually live considerably longer than the general population and people with moderate level of physical activity have a significantly lower risk of dying during the same time frame compared to the sedentary group. The relationship between exercise, fasting, and telomere length is a topic of significant interest and ongoing research especially in active and sedentary women . Therefore, the objective of this longitudinal study is to investigate the combined effect of exercise and fasting on telomere length, oxidative stress markers, metabolites and lipid profile.

METHODS: Twenty-nine young, non-obese, and healthy females were randomized into two groups: the first group (n=16) is the control group, they underwent a 4-week exercise training program, and the second group underwent 4-week exercise training program during while fasting for 14 hours (n=13). Blood samples were collected at baseline, and measurements of clinical traits, cytokines including IL-1 beta, IL-1RA, IL-6, IL-10, IL-22, MCP-1/CCL2, and TNF-alpha, and telomere length were performed before and after intervention.

RESULTS: Telomere length has increased significantly (p≤0.05) from the baseline in the exercise while fasting group, but showed no significant change in the control group. Moreover, a significant difference (p=0.02) was found in the mean change in telomere length between the two groups, together with reduced TNF-alpha (p=0.01) and energy fatigue (p=0.02) in exercise and fasting group compared to control group. Additionally, a significant positive correlation was observed between the mean change in telomere length and HDL in the exercise while fasting group only.

CONCLUSION: This study is the first to report an increase in telomere length after combining fasting with training, suggesting that exercising while fasting may be an effective tool for slowing down the aging rate. Further studies using larger and more diverse cohorts are warranted.

ESTIMATING AEROBIC CAPACITY OF MILITARY PERSONNEL USING BODY COMPOSITION INDEX

CHENG, Y.T., CHEN, J., LI, Y., CHEN, C., SHIH, Y.
UNIVERSITY OF TAIPEI

INTRODUCTION: Routine military training encompasses a wide range of physical activities such as walking, running, and jumping, imposing high physical demands on military personnel (1). The maximal physical capability of military personnel is high related with the maximal metabolism test (MMT) (2,3). However, traditional methods of measuring maximal metabolism are costly and complex, limiting their practical application efficiency. Thus, this study aims to analyze the most suitable combination of non-invasive body composition physiological parameters to predict military personnels MMT.

METHODS: Ninety-two male military personnel (age: 25.8 ± 3.5 years, height: 160.3 ± 3.9 cm, weight: 59.1 ± 8.5 kg) were recruited to undergo body composition analysis and MMT. Statistical methods employed included simple regression analysis and multiple regression analysis to construct the combination of physiological parameters most correlated with MMT.

RESULTS: Body fat percentage (BFP) has the highest coefficient of determination for MMT ($R2 = 0.215$, $p < 0.001$). The prediction model is [MMT = 51.79 – 0.394 × BFP]. The combination of BFP, resting heart rate (HRrest), and age has the highest coefficient of determination for MMT ($R2 = 0.401$, $p < 0.001$). The prediction model is [MMT = 74.39 – 0.345 × BFP – 0.150 × HRrest – 0.427 × age].

CONCLUSION: M Goran et al. mentioned that lean body mass (LBM) has a major influence on MMT. Obesity and overweight are not necessarily negatively related to MMT, but excess fat does have an adverse impact on submaximal energy metabolism (4). Gažarová et al. reviewed that human obesity status should not only refer to BMI, body weight or body fat mass, but also muscle mass and body fat mass to determine whether sarcopenia or obesity affects daily exercise performance (5). Increased body fat is related to a decrease in the MMT level of adolescents. In terms of parameters for predicting MMT, obesity represented by BFP is more suitable than BMI (6). Benno K et al. confirmed in 2020 that the correlation between MMT and LBM is higher than that of body weight, and less so (7), but the results of this study found that the combination of LBM and BFP showed that the regression statistics of LBM was not significant ($p > 0.05$), and only BFP can predict MMT ($p = 0.002$). The results of this study show that the combination of multiple physiological parameters such as BFP, HRrest, and age has a high coefficient of determination for predicting MMT to predict the maximum physical combat capability of military personnel, to shorten the assessment time and effectively allocate appropriate troop deployment.

OP-MH25 Exercise and COVID-19 II

EFFICACY OF A JUST-IN-TIME ADAPTIVE INTERVENTION IN MAINTAINING PHYSICAL ACTIVITY IN OLDER ADULTS DURING THE COVID-19 PANDEMIC.

MAIR, J., AGUIAR, E.J., BUCHAN, D., SCULTHORPE, N.
SINGAPORE-ETH CENTRE

INTRODUCTION: Nationwide lockdowns in 2020 due to the coronavirus pandemic severely limited opportunities to engage in physical activity (PA). Worldwide step count data has since shown that, on average, PA declined by 27% in the first 30 days since declaration of the pandemic [1]. Older adults were among those considered more vulnerable than others and were asked to stay home for longer. Just-in-time-adaptive-interventions (JITAIs) can be delivered remotely via smartphones, at scale, providing real-time 'in the moment' behaviour change support to people when they need it most. This study describes the efficacy of a personalised JITAI on PA in older adults during the COVID-19 pandemic.

METHODS: The JitaBug mHealth app delivered just-in-time PA promotion messages that were adapted using real-time PA (from Fitbit Charge 4), location, and weather data to encourage achievement of personalised PA goals. We tested the preliminary efficacy of JitaBug with older adults in a 6-week quasi-experimental study between October – December

2020. The intervention was delivered entirely remotely. Physical activity was measured using an Actigraph wrist-worn accelerometer during a baseline and follow-up period and using intra-day Fitbit data throughout the intervention. Actigraph data were processed using the GGIR package v2.1.0 and synchronised Fitbit data were analysed using the stepmetrics package v0.1.2 using R. Metrics of interest were time spent inactive and in low, and moderate-vigorous intensity PA, daily step count, and peak step cadence (as a proxy of intensity). Differences in PA between baseline and post-intervention were analysed using a paired-samples t-test.

RESULTS: Thirty-one older adults (mean ± SD; 65.5 ± 5.4 years) completed the intervention. Valid Actigraph and Fitbit data were obtained from n=27 and n=24 participants, respectively. There was no significant change in Actigraph-measured time spent inactive (mean difference; 10.2 mins; p=0.936), light intensity PA (-9.31 mins; p=0.98), or moderate-vigorous PA (-4.02 mins; p=0.835) due to the intervention. At baseline, average daily step count was 8581 ± 3559 steps/day, while peak30 and peak60 cadences were 86 ± 22 steps/min and 73 ± 22 steps/min, respectively, indicating overall low intensity PA.

CONCLUSION: The findings revealed that the JitaBug mHealth intervention supported older adults to maintain PA during the COVID-19 pandemic despite significant disruption to PA opportunities. JITAIs are a promising way to promote PA remotely to older adults in everyday life and may be used to reach those who may otherwise have limited access to PA support.

SLEEP AND PHYSICAL ACTIVITY CHARACTERISTICS IN UNIVERSITY STUDENTS DURING THE COVID-19 PANDEMIC: A DESCRIPTIVE CROSS-SECTIONAL WRIST ACTIGRAPHY STUDY

STEFANSDOTTIR, R., ROGNVALDSDOTTIR, V., ARNARSDOTTIR, A., GISLADOTTIR, T., JOHANNSSON, E., GESTSDOTTIR, S., JAKOBSDOTTIR, G.

UNIVERSITY OF ICELAND

INTRODUCTION: The COVID-19 pandemic impacted people's physical and mental health and affected countless individuals globally (1). University students are a subgroup that might be sensitive to changes as they are experiencing major life transition entering adulthood (2). Recent studies have reported that university students sleep behavior changed (3) during the pandemic and similarly, students reported a drastic decline in their physical and mental health (4). However, most studies during COVID-19 have solely relied on subjective data, and thus lacking information obtained with objective measures. The aim of the study was to objectively investigate the free-living sleeping patterns, clock times and physical activity (PA) characteristics of university students in Iceland during the pandemic, including exploring gender differences and the association between sleep and PA.

METHODS: Free-living sleep and PA were measured with wrist actigraphy (Actigraphy GT3X+) for one-week in January 2021 in 76 first year (24.4 ± 3.5 years) students (females 43%). Unpaired t-tests were used for gender comparisons and linear regression was used to evaluate the association between sleep and PA.

RESULTS: On average students went to bed at 01:41 hours (±78 min) and rose at 09:05 hours (±96 min). Females spent more time in bed, slept longer, and went to bed and rose earlier than males (all ps<0.05). No association was found between weekly PA counts and sleep duration, quality, variability, or social jetlag. However, a correlation between PA counts and bedtimes over the entire week was detected.

CONCLUSION: Findings from this descriptive analysis indicate that university students in Iceland sleep less than recommended and demonstrate a late sleep schedule. The COVID-19 pandemic affected sleep and physical activity differently in female and male university students as females went to bed earlier, slept longer and were more physically active compared to males. Earlier bedtimes correlated with higher PA counts, which could highlight the importance of practicing proper sleep hygiene and underline the importance of consistent sleep routine for overall health and well-being during challenging times or personal hardship.

DOSE-RESPONSE EFFECTS OF AN ONLINE, PRENATAL, AND POSTPARTUM PILATES-BASED PROGRAM ON LOW BACK PAIN, SLEEP DISTURBANCES, AND DEPRESSION DURING THE COVID-19 LOCKDOWN

MELONI, M., MANCA, A., VENTURA, L., CONSOLI, G., FENU, S., MURA, G., DERIU, F., CUGUSI, L.
UNIVERSITY OF SASSARI

INTRODUCTION: This study aimed to evaluate the effects of an online, prenatal Pilates-based program on low back pain (LPB) severity, sleep quality, mood, and depression levels in pregnant women. Additionally, the study sought to assess the potential benefits of continuing the training post-partum. Furthermore, we aimed to investigate the relationship between the amount of exercise and its impact on prenatal and post-partum outcomes.

METHODS: This study employed an exploratory, single-group pre-post intervention design. One-hundred and sixty-six pregnant women meeting specific eligibility criteria volunteered for this study (certified low-risk pregnancy; aged between 18 and 45 years; single pregnancy; gestational age between 20 and 28 weeks; normal BMI). Participants engaged in a Pilates-based telerehabilitation program during pregnancy and post-partum via an online platform. Outcome measures including weight control, LBP disability, sleep quality, mood, and mental health were assessed at baseline and after completion of both pre-partum and post-partum training.

RESULTS: Bonferroni-adjusted pairwise comparisons revealed significant gains in weight at large effect sizes only in low (+12.2%; p<0.0001) and intermediate-amount exercisers (+9.6%; p<0.0001), while high exercisers did not increase their weight in a significant manner (+3.8%; p=0.13). Adjusted pairwise comparisons revealed a significant increase in LBP-related disability in low (+93.1%; p<0.0001) and intermediate exercisers (+84.9%; p<0.0001), while high exercisers did not display significant increase in disability (+42.7%; p=0.21). Adjusted pairwise comparisons showed a significant increase in sleep disturbance in low-amount exercisers (<1.5 hours/week; +24.3%; p=0.005) but not in intermediate (1.5 to 3 hours/week; +4.6%; p=0.50) and high-amount ones (>3 hours/week; -0.1%; p=0.91). Pairwise comparisons showed significant increases in depression scores in all groups of exercisers, at large effect sizes (low-amount: +51.5%; p<0.0001; intermediate-amount: +42.9%; p<0.0001; high-amount: +35.6%; p=0.003). Regarding the effects of the post-partum intervention, pairwise comparisons revealed a significant reduction of sleep disturbances (-24.1%; p= 0.003) and depression scores (-15.9%; p=0.04) only in intermediate exercisers.

CONCLUSION: Approximately 270 minutes of home-based, tele-Pilates exercise were needed to prevent LBP worsening, and sleep deterioration in pregnant women. A different pattern was outlined for those women resuming the Pilates-based intervention at post-partum, with 150 minutes emerging as the "dose" of exercise capable to induce the largest improvements in LBP, sleep, and mood disturbances. Further research with larger sample sizes and control groups is needed to confirm these results and enhance methodological rigor.

CROSS-COUNTRY SKIING DEMAND INCREASED DURING AND AFTER COVID-19: A CASE STUDY FROM THE BLACK FOREST IN GERMANY

SCHMIDT, L., ROTH, R.
GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION

In early 2020, the Covid-19 pandemic caused major disruptions in all areas of society. While many public and private facilities were forced to close, outdoor recreation experienced a revival as people flocked to natural areas, using them as a place to socialise and build resilience in times of contact restrictions [1]. Few studies have investigated this effect in winter activities [2]. This study aimed to investigate pandemic-induced changes in cross-country skiing (XC) demand in the Black Forest, Germany, controlling for weather and temporal conditions.

METHODS

XC demand was recorded hourly using photoelectric sensors during the winter months of 2017-2023 (except 2020, when one sensor was missing). Weather data included air temperature (T), dew point (DT), sunshine duration (S) and precipitation (P) and were collected from nearby weather stations. In a 2017-2019 reference period, Spearman's rho (rs) and visual analysis of scatter plots determined the relationship between variables and XC demand. Correlated variables, interactions and XC demand from reference period were then used to train a quasi-Poisson (QP) model to predict XC demand in pandemic years, which were split into 2021 (lockdown), 2022 (eased restrictions) and 2023 (post-covid). The Mann-Whitney U test was used to identify significant (p<0.05) differences between XC demand in pandemic periods and QP model predictions.

RESULTS

Day-of-week (rs=0.4), time-of-day (rs=-0.3), DT (rs=-0.35), S (rs=0.34) and P (rs=-0.29) showed weak correlations with XC demand. Visual interpretation of scatter plots showed these correlations to be considerable. T did not correlate with XC demand (rs=0.0). However, a multivariate scatter plot analysis revealed a negative interaction between T and P in relation to XC demand, indicating that XC demand decreases when P occurs at higher T. Day-of-week, time-of-day, DT, S and the interaction of T and P showed a significant effect on XC demand in the QP model. XC demand in 2021 was 49% higher than QP model predictions (p<0.001). XC demand in 2022 and 2023 was 28% (p=0.009) resp. 22% (p=0.001) higher than QP model predictions.

CONCLUSION

Compared to pre-pandemic levels, XC demand was significantly higher in all pandemic periods studied. This study provides an example of a lasting effect of increased outdoor recreation demand, particularly in XC, after the pandemic. These findings highlight the importance of nature as a recreational space and of activities such as XC for psychophysical well-being and their social role as a source of resilience, especially in times of crisis [1]. Possible negative effects of increased demand, such as overcrowding and increased conflict potential, must not be neglected and require efficient and ongoing visitor management and monitoring, as well as appropriate training for natural area managers [3].

ASSOCIATION BETWEEN COVID-19 PANDEMIC AND OLYMPIC COMPETITIVENESS: DIFFERENT RESULTS FROM TOKYO AND BEIJING

CUI, D.1,2, GUO, J.2,3, ZHANG, X.2

1 CHINA INSTITUTE OF SPORT SCIENCE 2 CAPITAL UNIVERSITY OF PHYSICAL EDUCATION AND SPORTS

INTRODUCTION: The impact of COVID-19 pandemic on elite sports has been widely reported since 2020 [1]. Although many countries have undertaken elite sports recovery programs in Olympic preparations [2], many concerns remained ahead of the Beijing 2021 Summer Olympic and Paralympic Games and the Beijing 2022 Winter Olympic and Paralympic Games [3]. But without global post-Olympic evidence, it is hard to answer pre-Olympic concerns and measure the recovery of elite sports across countries. How and how much the intra-pandemic Olympic Games have been affected remains unknown. The aim of this study was to assess the association between domestic COVID-19 epidemic and global Olympic competitiveness of all the member countries.

METHODS: The investigated games were the Tokyo 2020 Summer Olympic and Paralympic Games, and the Beijing 2022 Winter Olympic and Paralympic Games. Competitiveness was characterized in both participation quotas and medal shares. For pandemic, transmission and symptoms were quantified by the number of infections and deaths, respectively. All data were collected from the Internet. Data were sourced from the official websites of 7 organizations, including IOC, IPC, WHO, UN Department of Economic and Social Affairs, Eurostat, Johns Hopkins University and Our World in Data. The Olympic variables were the change in participant share (CPS) and the change in medal share (CMS) for a country during the past Olympiad. The pandemic variables were the cumulative number of death cases (CDC) and CDC per unit of population (CDCP), and the cumulative number of the confirmed cases (CCC) and CCC per unit of population (CDCP). The study was conducted using SPSS 26.0 statistical software with 2-sided Pearson correlation analysis. Significance was set at $P<0.05$.

RESULTS: At the Tokyo Summer Olympics, CPS was most significantly positively correlated with CDC ($r204=0.27$, $P<0.001$) and CMS was most significantly negatively correlated with CDC ($r100=-0.46$, $P<0.001$). At the Beijing Winter Paralympics, CPS was most significantly positively correlated with CDCP ($r52=0.35$, $P= 0.010$) and CMS was most significantly negatively correlated with CCC ($r23=-0.51$, $P=0.013$). No significant associations were found between Olympic variables and pandemic variables at the Tokyo Summer Paralympics and the Beijing Winter Olympics.

CONCLUSION: At the Tokyo Summer Olympics, elite sports in urbanized countries with more severe pandemics recovered faster overall, but their medal competitiveness also declined more. This effect faded at the Beijing Winter Olympics, but appeared at the Winter Paralympics, highlighting the delayed impact of pandemics on global elite para sports. This study also demonstrates the power of multi-sourced Internet 'big data', and may inspire research across public health and elite sports and inform decision-making in elite sports recovery from pandemic.

THE ASSOCIATIONS OF ENJOYMENT AND PHYSICAL ACTIVITY ON THE DOMAINS OF SELF-CONCEPT AMONG HUNGARIAN ADOLESCENTS

BERKI, T., TÓTH, L., CSÁNYI, T.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

Introduction

One of the most important driving forces of sports activities is enjoyment, which reflects on feelings such as pleasure, liking, and fun. The enjoyment of sports has been studied extensively by researchers in recent years, but little is known about the relationship between the enjoyment of physical activity (PA) and physical education (PE). However, previous studies have shown that internal motivational factors, such as enjoyment, can positively influence young peoples psychological behavior. Therefore, our study aims to investigate the relationships between two forms of enjoyment (PA and PE) and students self-concept in early adolescence. We also investigate the role of physical activity on self-concept variables.

Material and methods

The sample consisted of 315 students ranging between 10-14 years old (Mage=12.63). Self-Description Questionnaire-I was used to measure the eight domains of Self-Concept (Reading, Mathematics, General School Concept, Physical Ability, Physical Appearance, Peer Relations, Parent Relations, and General Self-Concept). Enjoyment was measured with two scales. The Physical Activity Enjoyment Scale reflected PA enjoyment outside of school and the Factors Influencing Enjoyment of Physical Education Questionnaire reflected PE enjoyment in school. The short version of the International Physical Activity Questionnaire was used to assess the participants vigorous, moderate, and walking types of PA outside of the school. Hierarchical regression analysis was conducted on each self-concept variable.

Results

Our final model revealed that Vigorous PA were a significant predictor for Physical Appearance (β=.15) and Physical Ability (β=.19). PA Enjoyment were significant for General Self-concept (β=.29), Physical Ability (β=.28), Physical Appearance (β=.16), Peer Relation (β=.16) and Parent Relation (β=.22). PE Enjoyment significantly predicted General School (β=.17), Physical ability (β=.27), Peer Relation (β=.21) and Parent Relation (β=.22). Furthermore, boys perceived higher level on most of the domains of self-concept. The variance was explained by 44% of the highest and 5% of the lowest in our models.

Conclusions

Physical activity did not play a crucial role, which was indicated by only a few significant associations and the low effect values. However, enjoyment of PA and PE had a significant impact on self-concept. Both variables had a strong effect on social variables, and those who had a high level of enjoyment in both forms perceived better physical abilities. An interesting difference between the two forms of enjoyment is that the enjoyment of PA is general, while the enjoyment of PE strengthens the self-concept in school. This study highlights the importance of physical education since physical educators can contribute to creating a more positive school environment with the proper physical education class.

INTERVENTIONS WITH A FOCUS ON COGNITIVE ACTIVATION IN PHYSICAL EDUCATION: A SYSTEMATIC REVIEW WITH META-ANALYSIS

TÖPFER, C., ENGELHARDT, S., CARL, J., HAPKE, J.

FRIEDRICH-SCHILLER-UNIVERSITY JENA

Introduction

Conceptualizations such as Concept-based Physical Education or Teaching Games for Understanding (TGfU) highlight the importance of cognitive learning in PE. Cognitive activation is the in-depth mental engagement with sport and movement-related learning objects (Engelhardt et al., 2023). Five potential goals of cognitive activation in PE are suggested: (health-related) knowledge, motor skills, game performance and understanding, reflective ability and motivation (Engelhardt et al., 2023). We examined the effectiveness of interventions that focus on cognitive activation in PE.

Methods

A systematic review was conducted to analyse the current research situation in German- and English-speaking countries (Page et al., 2021). We searched in national and international databases (e.g., SPORTDiscus, Scopus) in the period from 2000-2022, using a variety of search terms reflecting the idea of cognitive activation (e.g., reflection, cognitive engagement). Title, abstract and full-text screening as well as data extraction and risk-of-bias assessment were carried out by two independent reviewers. We conducted a meta-analysis (Review Manager 5.4) with all controlled studies to assess their effectiveness (including sub-group analyses).

Results

We incorporated a total of 3.418 hits into the screening process (Cohens kappa: 0.75-0.96), resulting in 30 intervention studies being included in data extraction. The majority of the studies came from the USA and Spain. Half of the studies (n=15) followed a control group design. The majority of the intervention programmes were based on methodological approaches such as TGfU or 5-E-learning cycle. Empirical evidence of learning outcomes could be identified for (health-related) knowledge (g=0.54), motor skills (g=0.56), game performance and understanding (g=0.48), and motivation (g=0.39). Reflective ability was not empirically measured in any of the intervention studies.

Discussion

The systematic review demonstrated that cognitive activation in PE not only promotes knowledge-related outcomes, but also influences a variety of other outcome variables (e.g., motivation). However, there are limitations with regard to the scope of the data available. Due to the small number of studies with a control group design, further studies are needed to strengthen the robustness of the meta-analytical findings.

UNVEILING THE HOLISTIC TAPESTRY OF MOVEMENT, IDENTITY, AND WELL-BEING: INTEGRATING PHYSICAL ACTIVITY WITH AESTHETIC EXPERIENCE THROUGH CULTURAL KINETICS

XU, Y., HE, Z.

PEKING UNIVERSITY

Background and aim:

In the context of China, where cultural traditions are intricately woven into the fabric of daily life, the fusion of aesthetic experience with physical activity is not merely a method to encourage physical movement but a holistic approach to embrace cultural heritage. This research explores innovative methodologies that amalgamate cultural-heritage-inspired aesthetic experiences with physical activity, aiming to enhance holistic physical and socio-cultural well-being among higher education participants.

METHODS: An active research was conducted. We developed and executed two experiential workshops in collaboration with multidisciplinary experts, drawing inspiration from cultural heritage to blend aesthetic experience with physical activity. These workshops, open to students and faculty in higher education, were evaluated through qualitative surveys and semi-structured focus groups. The first workshop integrated ancient Chinese poetry, Guqin music, and classical dance to create a comprehensive learning environment that nurtures body, mind, and spirit. The second workshop, centered around Kunqu opera, encouraged participants to engage with opera-style physical movements and contemplate gender and identity aesthetics through the roles of Sheng (male) and Dan (female).

RESULTS: The incorporation of cultural heritage into physical activity fostered a unique and immersive learning experience, enriching participants' understanding of body movement, cultural identity, and holistic well-being. Feedback highlighted the benefits of immersive learning, collaborative group dynamics, the interdisciplinary mentorship, and the synthesis of practice and performance. The majority of participants reported enhanced imagination and creativity in physical movement and activity.

Conclusions:

These workshops conducted in this active research transcend traditional physical education by highlighting the synergy between physical, cultural, and aesthetic dimensions of well-being. They advocate for physical literacy as a pivotal element of a holistic, culturally enriched lifestyle in China, thereby broadening the cultural significance of physical activity.

GENERATIONAL DIFFERENCES IN PROMOTING EXERCISE BEHAVIOR THROUGH MOBILE PHONE APPLICATIONS: THE MEDIATING ROLE OF COGNITIVE INVOLVEMENT AND AFFECTIVE INVOLVEMENT

SU, R., MENG, M., CHEN, C., CHEN, L., WEI, W., WANG, D.

BEIJING NORMAL UNIVERSITY

Introduction: Mobile phone applications are impacting and changing the health concepts and behaviors of individuals in the different generations in China. In this study, based on the Stimulus-Response theory, we construct a dual-path mediation model to reveal the mechanism through using mobile phone applications influences exercise behavior while considering generational differences.

Methods: This study using a stratified random sampling method, finally 4390 samples were selected from 32 provinces in China. Using mobile phone applications behavior, cognitive involvement, affective involvement, and exercise behavior were measured through questionnaire. Statistical analysis used the product coefficient method, exploring relationships between variables through structural equation modeling, and the intermediate effects of the model are estimated through the Monte Carlo bootstrapping method. Furthermore, stratified regression analysis is applied to test the moderating effects of generational differences. Data analysis was performed using R program version 4.10 and Amos 20.0, with a significance threshold set at $p < 0.05$.

Results: (1) Cognitive involvement as a significant mediator in the relationship between using mobile phone applications and exercise behavior ($Z = 3.40$, 95% CI [0.08, 0.28], $p < 0.001$). (2) Affective involvement shows a positive influence on cognitive involvement, and both emotional and cognitive involvement as significant the chain mediating roles in the connection between using mobile fitness applications and exercise behavior ($Z = 3.29$, 95% CI [0.06, 0.23], $p < 0.001$). (3) The moderating effect of the different generations in promoting exercise through using mobile fitness applications is not significant (difference = -0.05/0.05/0.09, SE = 0.08/0.08/0.06, $p = 0.55/0.54/0.13$).

Conclusion: Using mobile phone applications serves as a beneficial approach to exercise behavior, and cognitive involvement and affective involvement mediate the relationship between using mobile phone applications and exercise behavior. There is no generation difference in the using mobile phone applications and exercise behavior.

ECHOES OF SILENCE: EVALUATING THE EFFECTS OF AUDIENCE RESTRICTIONS ON ELITE GOLF PERFORMANCE

LUNDKVIST, E., LARSSON, R., KALÉN, A.
UMEÅ UNIVERSITY

Introduction

The unique circumstances of the COVID-19 pandemic offered an opportunity to study the effect of audience presence on athletic performance. This research focused on professional golf, an individual sport where performance can be quantitatively measured, providing a clear view of the impact of spectators. Drawing on theories of social facilitation [2, 3] and psychological pressure[4], this study aimed to explore how the presence, absence, and limited presence of spectators influenced PGA TOUR golfers performances over the 2018-2022 seasons. This exploration is rooted in the broader context of how environmental factors affect athletic performance, contributing to the ongoing discussion in sports psychology and performance analysis.

Methods

The performance of 832 professional golfers across five seasons (103 00 golf rounds) of the PGA TOUR was analysed before, during and after audience restrictions. Performance metrics were examined using two-level linear mixed models [1].

Results

The findings revealed a complex relationship between audience presence and golfer performance. Overall, players performed best in the absence of spectators. Conversely, the presence of an audience following the pandemic showed better performance levels than with audience before the pandemic, indicating a possible effect of the decision making learned without an audience. Notably, experience and skill level of the players did not interact with these results.

Discussion

The study highlights the nuanced interplay between athlete performance and audience presence, suggesting that presence of spectators influence professional golfers performance. This research extends the understanding of social facilitation in sports, emphasizing the need for personalized approaches in athlete preparation and coaching. Future research directions include using underlying performance measurements to understand what parts of the game where the players performed differently, qualitative interviews to get the players experiences of playing with and without an audience and physiological measurements to further understand what might cause the differences.

EFFECTS OF PRESSURE AND MOVEMENT REINVESTMENT ON PERFORMANCE IN EXECUTION-ONLY AND DYNAMIC FOOTBALL SHOOTING TASKS

SULLIVAN, R., UIGA, L.1, MASTERS, R.S.W.3, ANSON, G.1, NIEUWENHUYS, A.1
1 UNIVERSITY OF AUCKLAND; 2 MANCHESTER METROPOLITAN UNIVERSITY; 3 UNIVERSITY OF WAIKATO

Introduction

The Theory of Reinvestment predicts that pressure negatively impacts expert players' execution of perceptual-motor skills, due to conscious reinvestment of explicit knowledge about how to perform the skills (i.e., 'conscious motor processing'). The current project examined whether trait reinvestment and conscious motor processing can explain effects of pressure in 'execution-only' and 'dynamic' performance situations, where opponents' actions may require the sudden cancellation or adaptation of ongoing movement.

Methods

Across four studies, experienced football players performed shots on goal against a goalkeeper and defending players who either stood still ('execution-only'; Study 1, n = 30) or who occasionally moved to intercept players' shots ('dynamic'), in which case players were instructed to completely inhibit (Study 2, n = 15) or redirect their shots (Study 3, n = 30; and Study 4, n = 30). Performance pressure was manipulated by means of an evaluative audience or a combination of contingencies (monetary reward, video recording, error feedback). Players' trait reinvestment was determined with the Movement Specific Reinvestment Scale. Conscious motor processing was assessed using established questionnaires or by means of

a skill-focused dual-task. Measures of performance included shooting accuracy, inhibition/redirection success, reaction- and shot completion times.

Results

Findings from Studies 1 and 2 indicate that pressure did not significantly impact conscious motor processing or shooting accuracy. In Study 2, anticipated goalkeeper movement, caused attention to shift away from the target and towards the goalkeeper (p =.003), resulting in reduced shooting accuracy (p = .01). Furthermore, players who were characterized as high trait reinvestors showed greater inhibition success under pressure (p = .04). Studies 3 and 4 are currently ongoing and results will be available at the time of presentation.

Discussion

Findings thus far suggest that anticipation of goalkeeper movement (i.e., dynamic performance situations), negatively impacts target-related attention and shooting accuracy in football players. In addition, findings suggest that pressure may facilitate inhibitory performance in those players who go about their skill execution in a deliberate and self-conscious manner. Results from Studies 3 and 4 will reveal whether these results extend to situations where players redirect rather than inhibit their shots in response to goalkeeper/defender movement and further uncover potential benefits of trait reinvestment.

INHIBITORY CONTROL MEDIATES THE ASSOCIATIONS BETWEEN MODERATE-TO-VIGOROUS PHYSICAL ACTIVITY AND ADOLESCENTS` OFF-TASK BEHAVIOR IN THE CLASSROOM

BERGER, M., GERBER, M., BRAND, S., MÖHRING, W., PÜHSE, U., LYDIGA, S.

UNIVERSITY OF BASEL

Background: Off-task behavior in the classroom means not focusing on the current learning task but fidgeting, making noise, or being passive. Individual cognitive states and profiles may underlie this behavior. Accumulating evidence suggests that moderate to vigorous physical activity (MVPA) benefits academic behavior (1, 2) and a set of cognitive abilities (3). However, it remains unclear if these MVPA-related cognitive benefits translate into reduced off-task behavior.

Aim: This cross-sectional study investigates the direct association between MVPA and off-task behavior as well as mediations by different cognitive domains in adolescents.

Sample: 46 male and 67 female adolescents aged 13 ± 1.3 years were recruited from local schools in the greater area of Basel, Switzerland.

Methods: Participants recalled their MVPA with the 7-day physical activity recall protocol. Using video cameras, their classroom behaviours were recorded and a 6-min period was rated for off-task behaviour. Additionally, participants completed computerized cognitive tasks in a group setting. The tasks encompassed a modified Flanker task, which assessed both inhibitory control and cognitive flexibility, a Sternberg paradigm, which assessed working memory, and an Emotion Recognition task.

Results: Path-analyses revealed that higher MVPA was associated with less off-task behaviour. Inhibitory control accounted for a partial mediation of this association. The mediating role of inhibitory control was most pronounced for the relation between MVPA and off-task behaviours related to noise (e.g. speaking out of turn).

Conclusion: These findings provide a first indication that curricular and extracurricular physical activities targeting specific improvements in inhibitory control may promise transfer effects to favourable classroom behaviours.

SELECTIVE ATTENTION OF ELITE VERSUS YOUTH BIATHLETES IN REST AND AFTER PHYSICAL LOAD

BIRKLBAUER, J., DIRNBERGER, J.1,2, BUCHECKER, M.1, SATTLECKER, G.3, FINKENZELLER, T.1, KÖSTERS, A.1, WIESINGER, H.P.1,4

1: DEPARTMENT OF SPORT & EXERC SCI, UNIVERSITY OF SALZBURG; 2: OLYMPIC TRAINING CENTER SALZBURG; 3: INTERNATIONAL BIATHLON UNION; 4: INSTITUTE OF NURSING SCI & PRACTICE, PARACELSUS MEDICAL UNIVERSITY

INTRODUCTION: Attention abilities are critically important for performance in self-paced and far-aiming sports, enabling athletes to focus on targets and resist distractions. Accordingly, elites in shooting and archery showed better selective attention compared to their lower-level counterparts (1). In biathlon, demands on attention are arguably even greater, as shooting has to be completed under time constraints and significant physical exertion. First indications of enhanced conflict control in biathletes with superior shooting performance were derived from cluster analyses (2). Based on these preliminary findings, we hypothesized that elite outperform youth biathletes in visual interference control of attention during rest and even more after physical exertion.

METHODS: Twenty-six youth biathletes (14 males; 15.4±1.1 yrs of age) and 14 European and World Cup biathletes (10 males; 22.7±3.1 yrs) fired 3 x 5 shots in prone and standing shooting positions without physical load followed by 2 x 5 shots in both positions during a simulated pursuit race. According to their usual race distance, elites had to roller ski 5 loops of 2.5 km and youth 5 loops of 1.5 km in their individual race pace. Selective attention was assessed using a modified Eriksen-Flanker Task both before the rest condition and after the simulated competition. 50m-shooting performance was measured on a scale from 0 to 10 rings.

RESULTS: Frequentist 2-way ANOVAs revealed neither significant group differences ($p>.562$) nor interaction effects ($p>.302$) in the interference scores or incongruent trials of response times (RT) and errors with low effect sizes ($\eta2p<0.028$). These findings were supported by Bayesian analyses providing anecdotal to moderate evidence in favour of no group (BFincl<0.544) or interaction (BFincl<0.453) effects. With large effects ($\eta2p>0.165$) and strong evidence supporting a change (BFincl>11.6), RT improved from pre to post test in both incongruent and congruent trials by 14±28 ms ($p=.002$) and 14±25 ms ($p=.009$), respectively. Elites outperformed youth athletes in their shooting performance ($p<.001$; $d=1.991$) with decisive evidence (BF10>1000).

CONCLUSION: Our findings contradict previous results in conventional shooting and archery sports, as elite biathletes showed no better flanker conflict control than youth. Hence, selective attention, as measured by the Flanker Task, seems not to be a determining factor for biathlon performance. Mindfulness training, which has been shown to improve the attention networks in elite shooters and archers (1), may not be as promising in biathlon. The improvements in RT after the simulated race are in line with the observation that maximum physical exhaustion facilitates information processing speed in the Flanker Task (3), which can be explained by the astrocyte-neuronal lactate-shuttle hypothesis.

A STUDY ON THE CHINESE TAIPEI TOP-TIER BADMINTON PLAYERS' SPONSORSHIP

TSENG, Y., CHENG, S.

TSINGHUA UNIVERSITY

Introduction

Sports sponsorship has become a vital strategy in corporate marketing. While sponsorships involving sports events, organizational entities, and venue naming rights are common, athlete endorsements often yield superior results. However, conflicts between athletes and sponsoring brands frequently arise, which few of the previous researches in Chinese Taipei have been discussed from the perspective of athlete endorsements. This paper supplements this perspective, aiming to understand the overview of corporate sponsorship of badminton in Chinese Taipei, the current status of athletes receiving corporate sponsorship and their understanding of sponsorship. The goal is to foster mutually beneficial relationships between corporations and athletes.

Method

This study employs a semi-structured interview method. Data collection is based on the theoretical framework formed around the four major benefits of sports sponsorship proposed by Howard and Crompton (1995), the basic standards of endorsers proposed by Micik and Shanklin (1994), and the "FRED (representing Familiarity, Relevance, Esteem, and Differentiation)" principle of ideal endorser selection factors proposed by Cheng (2001). Ten top badminton players from Chinese Taipei, who have participated in the Olympic event, are selected for interviews. Data analysis involves coding the interview text according to the interview outline, followed by classification, reorganization, and comparison with existing literature.

Results

(1) Enterprises and corporate teams have established performance-oriented signing mechanisms, tending to provide excellent sponsorship resources for top athletes. They primarily assess athletes based on the professionalism of their sports projects, competition results, social image, and potential when selecting athletes as brand endorsers or training targets. (2) Athletes have a certain understanding of the traits of endorsers and how to maintain good relationships with sponsors, but their understanding of sponsorship concepts and long-term partnerships with sponsors is limited. (3) Sponsorship conflicts often occur when athletes receive sponsorships from similar enterprises, which are often caused by competition between enterprises.

Discussion

To promote better cooperation and reduce sponsorship conflicts, athletes should understand the basic concepts of sports sponsorship and the traits required of endorsers. Management departments should address issues such as lack of resources for athletes and encourage enterprises to invest in sports sponsorship to improve athletes competitive levels and promote sponsoring enterprises.

HOW SCENE FEATURES OF E-COMMERCE LIVE STREAMING INFLUENCE CONSUMERS' PURCHASE INTENTION? AN EMPIRICAL STUDY FROM THE FIELD OF SPORTING GOODS

LI, Z., GUO, Z.1, WANG, Y.2

1.TSINGHUA UNIVERSITY; 2.SHANGHAI UNIVERSITY OF SPORT

Introduction

The scale of live-streaming users reached 765 million, and the transaction scale in 2022 reached 3.5 trillion in China. Live streaming has offered new opportunities for retailers to increase their sales (Zheng et al., 2023). Many sporting goods brands began to take advantage of live-streaming platforms to improve product sales volume. Previous research focused on the anchors' features how to impact the purchase intention; however, the underlying mechanism by which scene feature influences consumers' purchase intention is still unknown. Thus, this study aims to explore the relationship between purchase intention (PI) and scene features, which include visual appeal (VA), presence (PR), scene-product matching (SM) in the sporting goods field. Flow experience (FE) and sport identification (SI) as mediating and moderating variables respectively.

Methods

Data were collected through snowballing referrals on social software (i.e., WeChat and QQ) and several anchor's fan groups of sporting goods e-commerce live streaming via an online questionnaire from March 10 to 20, 2023. 340 valid questionnaires were gathered. Using structural equation modeling to analyze the path influence relationship between the variables and test hypotheses through SPSS26.0 and AMOS 26.0.

Results

Firstly, VA ($\beta = 0.24$, $p = 0.008$), PR ($\beta = 0.31$, $p < 0.001$) and SM ($\beta = 0.39$, $p < 0.001$) positively impact FE. From the perspective of the path that scene features affect PI, VA ($\beta = 0.31$, $p = 0.009$), PR ($\beta = -0.03$, $p = 0.751$), and SM ($\beta = 0.32$, $p = 0.003$). Moreover, FE contributes positively to PI ($\beta = 0.26$, $p = 0.036$). The variances explained for FE and PI are 0.67 and 0.82, respectively. Secondly, FE has a significant mediating effect between scene features (i.e., VA, PR, SM) and PI; the mediating effect accounts are 45.3%, 72%, and 44.4%, respectively. Thirdly, the regression coefficient of interaction term (FE×SI) is 0.001 ($t = 0.16$, $p = 0.987$), indicating that the model's explanatory power is weak.

Discussion

This study totally proposed 11 hypotheses while two were refused. We suggested that sporting goods vendor create an attractive and matching scene to enhance PI. An authentic outdoor environment as the scene can give consumers a more immersive feeling than using a virtual store. PR has no significant effect on PI, which echoes previous conclusion. The consumer is relatively rational and objective, and needs more factors to stimulate the purchase intention. Moreover, a strong sales atmosphere makes consumers who watch e-commerce live streaming to get pleasure may have antipathy. Contrary to prior research in the United States. SI has no significant moderating effect between FE and PI. Consumers with low SI can buy sporting goods for fitness activities. In addition, the main crowd is young people, who buy it for liking sporting trend culture or impulse buying.

THE MEDIATION EFFECT OF INVOLVEMENT BETWEEN SERVICE QUALITY, SATISFACTION, AND BEHAVIOR INTENTION IN FITNESS CENTER

HUANG, C.H.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: The fitness industry in Taiwan has experienced rapid growth over the past decade. As customers increasingly demand high-quality service from fitness centers, it has become imperative for these establishments to provide top-notch sports and recreation services. Given that service quality is central to the mission of sport and recreation centers, understanding the nature of service quality is of paramount importance. Customers play a significant role in focusing on service quality and identifying what they perceive as quality in the fitness market, especially in terms of satisfaction and behavioral intention.

In the fitness industry, consumers participation in exercise, engagement with specific sports centers, and involvement in fitness center services indicate the importance of involvement. Service encounters influence the leisure experience of

participants and act as antecedents of activity involvement. Involvement represents an internal state variable that reflects the amount of arousal and interest to engage in an activity and serves as a mediator of consumer behavior.

This study aims to explore the relationship among service quality, involvement, satisfaction, and behavior in fitness centers in Taiwan. Additionally, it seeks to examine the mediating effect of participant involvement between service quality, satisfaction, and behavioral intention.

Method:

For this study, a questionnaire was designed to investigate the service quality, involvement, satisfaction, and behavior intention of fitness center participants, utilizing a five-point Likert-type scale. First, Exploratory Factor Analysis (EFA) was employed to extract the main items of service quality and involvement. Subsequently, the primary factorial dimensions of service quality and involvement were incorporated into Structural Equation Modeling to examine the relationships among service quality, involvement, satisfaction, and behavior intention. Finally, the mediation effect of involvement between service quality, satisfaction, and behavior intention was also tested.

RESULTS: In the EFA, there were initially 21 items for motivation, resulting in the extraction of four factor dimensions: Employees, Ambience, Price, and Convenience. According to the Structural Equation Modeling, the results showed that service quality positively and significantly influences satisfaction, behavior intention, and involvement. Involvement positively and significantly affects behavior intention but does not significantly influence satisfaction. Through bootstrapping within a 95% interval, it was found that both the direct and indirect effects are significant for both satisfaction and behavior intention. Involvement partially mediates the relationship between service quality, satisfaction, and behavior intention.

Discussion:

Service quality holds significant importance in the fitness industry in Taiwan. To enhance customer satisfaction and behavioral intention, fitness center managers should closely monitor the quality of the ambience and employees within the physical environment. Participants perceive the importance of engaging in an activity based on perceived quality in fitness centers, and involvement mediates the relationship between service quality, satisfaction, and behavioral intention. A higher level of customer involvement corresponds to greater input into the service delivery process and, consequently, the final outcome.

ENVIRONMENTAL SUSTAINABILITY GOVERNANCE IN MEGA SPORT EVENTS: INSIGHTS FROM FIFA WORLD CUP 2022 PRACTICES

YAO, F., WANG, P., LIU, B., GUO, Z.
TSINGHUA UNIVERSITY

Introduction

Multiple stakeholders are highly involved in environmental sustainability governance when holding mega sports events, as governance subjects to influence governance outcomes. Therefore, it is necessary to summarize an environment sustainability governance model in a mega event, especially from the collaborative stakeholder perspective. This paper aims to analyze how stakeholders collaborate upon environmental sustainability issues in the case of FIFA World Cup Qatar 2022 (FWC 2022).

Methods

Original materials of this empirical case study are derived from open sources, including academic journals and book chapters, official reports and documents from FIFA and FWC 2022, media releases etc. We proceed with these materials in three steps. Firstly, providing explanation of the SFIC analytical framework. Secondly, categorizing the stakeholders of FWC 2022, and extracting the four governance elements in line with that in the SFIC model. Thirdly, concluding a framework for future mega sports events on environmental sustainability governance.

Results

According to SFIC collaborative governance model, it divides collaborative governance into four main stages: starting conditions (S), leadership facilitation (F), institutional design (I), collaboration process (C) and followed governance outcomes. FWC 2022 has showed a typical example of applying stakeholder collaborative governance in environmental sustainability practices. Starting with stakeholder identification stage, the critical tournament stakeholders can be identified into internal and external groups. In the leadership facilitation stage, sustainability management system (SMS) is established for clear leadership roles, responsibilities, and governance structures. In the institutional design stage, the sustainability policy and strategy were designed as the fundamental guide of the tournament and formed the basis of the SMS and stakeholder engagement. Followed the collaboration process, stakeholder collaborative governance practices on environmental sustainability are achieved through trust building with dialogue, commitment based on a materiality assessment, shared understanding on sustainability vision and missions, collaborative behaviors and outcomes on sustainable building, low-emission solutions, waste and water management.

Discussion

Extracting insights from the case of FWC 2022, the stakeholder collaborative governance framework can be a valuable reference for future environmental sustainability efforts in mega sports events. The initial element of the framework is to identify relevant stakeholders, then build governance structure with facilitate leadership and clear rules, for achieving the collaborative governance as an iterative process of dialogue, trust, commitment, understanding factors. It is also im-

portant to note here that the realization of a collaborative stakeholder governance process cannot be achieved in the short term but requires prior planning and preparation.

DOES SPORTING GOODS MANUFACTURING INDUSTRY AGGLOMERATION HAVE ECOLOGICAL SPILLOVER EFFECT? ——A SPATIAL REGRESSION ANALYSIS BASED ON CHINA'S PROVINCIAL DATA

ZHANG, R., YAO, F., GUO, B., NIU, J., LI, X., TSENG, Y., ZHANG, C.
PEKING UNIVERSITY

Introduction

As a core sector of Chinas sports industry, the sports goods manufacturing industry accounts for over 50% of the total output, with industrial agglomeration being a notable characteristic. This paper focuses on the ecological externality of this phenomenon, aiming to leverage the industrys spatial spillover effects to promote sustainable development in the regions.

Methods

The research subject of this paper is the sports goods manufacturing industry across 30 provinces in China, from 2012 to 2016 and from 2018 to 2019 (data missing for 2017). Provincial-level industrial agglomeration is calculated using Excel 2019, while ecological efficiency is calculated using DEA-SOLVER Pro 5.0 software. Based on the STIRPAT theory, exploring spatial data analysis and spatial regression analysis were conducted using Open GeoDa 1.16 and STATA 15.0 software. The spatial Durbin model was employed to analyze the relationship between sports goods manufacturing industry agglomeration and ecological efficiency. Other explanatory variables include demographic, economic, and technological factors, while control variables encompass industrial structure, urban development, environmental governance, and opening up factors.

Results

(1) The spatial autocorrelation results indicate that ecological efficiency exhibits a "low-low" agglomeration pattern, concentrated in the Northwest China. The sports goods manufacturing industry demonstrates both "high-high" and "low-low" agglomeration patterns, with the "high-high" agglomeration distributions observed in the Southeast China. (2) The panel model results reveal an inverted U-shaped relationship between the high-level agglomeration areas and regional ecological efficiency. (3) The effect decomposition results of the spatial panel model indicate that the direct and total effects of industrial agglomeration in the sports goods manufacturing industry are significantly positive. Among the explanatory variables, the direct effects of demographic and economic variables are significantly negative, while the spillover and total effects are significantly positive, with technological variables exhibiting the opposite pattern. Within the control variables, the spillover and total effects of industrial structure, environmental governance, and urbanization variables are significantly negative, whereas the opening up variables exhibiting the opposite pattern.

Discussion

Currently, the agglomeration of China's sports goods manufacturing industry exhibits significant regional disparities and demonstrates a positive trend in ecological externalities within the region, surrounding areas, and nationwide. This trend manifests as an initial increase followed by a decrease in the impact on regional ecological efficiency, resulting from the combined effects of population, economic, technological, and other urban development factors. Future agglomeration expansion should focus on pollution control and environmental protection efforts.

OP-AP15 Cycling: Training Interventions and Demands

A MICROCYCLE WITH MODERATE-INTENSITY INTERVAL TRAINING IMPROVES ENDURANCE PERFORMANCE IN WELL-TRAINED CYCLISTS

SINDRE MØLMEN, K., ODDEN, I., SØRENSEN, M., RØNNESTAD, B.
INLAND NORWAY UNIVERSITY OF APPLIED SCIENCES

INTRODUCTION: To organize training into shorter periods of time with specific training focuses has become increasingly common for endurance athletes in recent years. Particularly, organizing high-intensity interval training sessions in microcycles has been well-studied and found to improve endurance performance-related variables [1]. There is, however, little evidence on how efficient similar type of training strategy is when performing moderate-intensity interval training (MIT) in well-trained endurance athletes. Here, we compare the physiological effects of a seven-day MIT microcycle with a time-matched period with usual training (CON) in well-trained cyclists.

METHODS: Using a randomized crossover design, 30 male cyclists (maximal oxygen consumption (VO2max),70.5 (4.6) mL/min/kg) performed both a MIT microcycle and CON training. Sixteen and 14 of them started with the MIT microcycle and CON training, respectively. The MIT microcycle consisted of six interval sessions distributed over seven days. In con-

secutive days, except for a rest day on the 4th day, they performed interval sessions with 7x10 min, 6x12 min, 5x14 min, 7x10 min, 5x14 min, and 6x12 min work periods, with the aim of hitting 14-15 on the Borg 6-20 rating of perceived exertion (RPE) during the work intervals (equivalent to a perceived exertion of "somewhat hard" to "hard"). A six-day taper period was carried out before physiological testing. The efficacy of the MIT and CON training was measured as changes in 15-min maximal average power output (PO15min), power output at 4 mmol/L [blood lactate] (PO4mmol), mean power output achieved during the last minute of an incremental test (pVO2max), and VO2max.

RESULTS: Average RPE during work intervals in the MIT microcycle was 14.4 (0.3), which corresponded to 66.4 (4.8) % of pVO2max, 85.3 (3.3) % of maximal heart rate, and 2.8 (1.1) mmol/L [blood lactate]. The MIT microcycle led to significantly larger improvements than CON on PO4mmol (4.0 (4.4) % vs. -1.3 (3.7) %, respectively; p<0.001) and pVO2max (2.5 (4.5) % vs. -0.7 (3.9) %, respectively; p=0.007), while changes in PO15min were not statistically different between interventions (3.9 (8.3) % vs. 0.2 (6.8) %, respectively; p=0.138). VO2max tended to increase more following MIT than CON (2.0 (3.9) % vs 0.0 (3.5) %, respectively; p=0.055).

CONCLUSION: Six MIT sessions distributed over seven days followed by a taper period induced larger improvements in measures of endurance performance than a time-matched period of usual training in well-trained cyclists.

REPLACING LOW INTENSITY ENDURANCE EXERCISES WITH HIGH INTENSITY MICRO-INTERVALS

MATOMÄKI, P.

UNIVERSITY OF JYVÄSKYLÄ

INTRODUCTION: Typically, low intensity endurance exercise (LIE) is performed as a continuous session below the first lactate threshold. However, this is not the only way to execute LIE. High intensity micro-intervals, which should not be confused with maximal sprint interval exercises, are exercises, where work phase lasts at most 15 seconds at ~100% VO2max and recovery period is at least twice as long. These intervals mimic LIE metabolically and cardiopulmonarily [1]. The energy during micro-intervals is produced aerobically using oxygen from the myoglobin stores [1, 2]. Therefore, micro-intervals are highly promising stimulus for peripheral aerobic adaptations, as well as for neuromuscular system adaptations, as muscles operates at or near 100% VO2max with minimal anaerobic component and metabolic cost.

However, little is known about the feasibility and usability of such intervals in the long-term training. The aim of the present study was to investigate whether high-level cyclists' LIE can be replaced with high intensity micro-intervals.

METHODS: In this quantitative-qualitative pilot study, three national-level cyclists (one female) progressively replaced majority of their LIE with micro-intervals for 10 weeks. They underwent a VO2max test and a 6-minute time trial before and after the intervention. To monitor the stressfulness of the training, they completed total quality recovery -scale [3] each morning. Finally, they were interviewed immediately after the intervention.

RESULTS: During the 10-week intervention, the cyclists accumulated 12.5–14.0 h (9–14% of all training time) above VO2max intensity, which accounted for 65–99% of the amount they accumulated during the entire year prior. The cyclists became accustomed to micro-intervals and reported neither cumulative fatigue nor a decrease in total quality recovery. 6-min time trial improved 12–27 W (3–7%), while there were no changes in VO2max.

CONCLUSION: A novel finding was that the extensive use of high intensity micro-intervals is a feasible method for athletes; Micro-intervals do not induce excessive fatigue, they allow athletes to accumulate a large amount of high intensity time, and they provide positive performance adaptations. However, the optimal way to include micro-intervals into training and their role in training programming still need thorough examination.

NOVEL INSIGHT INTO THE CALCULATION OF PURE MAXIMAL GLYCOLYTIC RATE USING THREE ENERGY SYSTEM CONTRIBUTIONS

YANG, W.H., PARK, S., GEHLERT, S.

CHA UNIVERSITY

INTRODUCTION: The glycolytic system supports the metabolic energy requirements during intense exercise. The formula of maximal glycolytic rate (Mader's model) is considered the delta lactate between maximal blood lactate accumulation after a 10-15 s exercise and resting blood lactate levels are divided by the difference between the total exercise time and phosphagen system-contributed time (tPCr). However, this formula does not subtract the energy contribution of oxidative metabolism. Furthermore, tPCr is assumed in which no lactate production takes place ("fictitiously") although it is well known that lactate production occurs independently of oxygen availability under anoxic, hypoxic, and normoxic conditions. The point of –3.5% from the peak power output (tPCr –3.5%) was utilised in previous studies without providing an in-depth explanation on why the decreased 3.5% time point of the peak power output was used as tPCr. However, this method was based on an error in the early SRM cycle ergometer. Therefore, we modified the limitations of the previous formula and compared different calculations of the maximal glycolytic rate.

METHODS: Calculations of the maximal glycolytic rate were based on the differences in defining the phosphagen-contributed time and incorporating the oxidative energy system contribution. In different calculations of the maximal glycolytic rate, tPCr –3.5%, tPCr–peak (the time until peak power output using the latest SRM cycle ergometer [± 0.5-1% error]), and incorporation of the oxidative energy system contribution for pure maximal glycolytic rate using the analysis of the PCr-La–-O2 method during a 15-s maximal cycling test were used.

RESULTS: The level of maximal glycolytic rate (tPCr –3.5%) was higher than pure maximal glycolytic rate and maximal glycolytic rate (tPCr–peak) while maximal glycolytic rate (tPCr–peak) was lower than pure maximal glycolytic rate ($p < 0.0001$, respectively). A very high association between pure maximal glycolytic rate and maximal glycolytic rate (tPCr–peak) was observed ($r = 0.99$). This association was higher than the relationship between pure maximal glycolytic rate and maximal glycolytic rate (tPCr –3.5%) ($r = 0.87$).

CONCLUSION: Pure maximal glycolytic rate as a novel calculation of maximal glycolytic rate provides more detailed insights into inter-individual differences in energy and glycolytic demands than other calculations of maximal glycolytic rate (tPCr–peak and tPCr –3.5%). In particular, because oxidative and phosphagen contributions can differ remarkably between elite track cyclists, implementing those values in pure maximal glycolytic rate can establish more optimized individual responses for elite track cyclists.

HEAT SUIT TRAINING MAINTAINS THE INCREASED HAEMOGLOBIN MASS AFTER ALTITUDE TRAINING CAMP IN ELITE CYCLISTS

URIANSTAD, T., RØNNESTAD, B.R., ODDEN, I., HANSEN, J., MØLMEN, K.S., CARDINALE, D.

INLAND NORWAY UNIVERSITY OF APPLIED SCIENCES

INTRODUCTION: Altitude training may increase haemoglobin mass (Hbmass) and improve sea-level endurance performance in athletes [1]. As a result, training and residing at high altitudes (>2000 m above sea level) have gained popularity among endurance athletes preparing for competitions at low altitudes [2]. However, the Hbmass gained during altitude camps typically diminishes rapidly upon returning to sea level [3]. Intriguingly, prolonged heat training-induced increase in Hbmass has been shown to be maintained for three weeks by performing only three 50-minute heat suit training sessions per week in elite cyclists [4]. The present study aimed to explore whether a similar approach can maintain increased Hbmass after an altitude training camp in elite cyclists.

METHODS: Eighteen elite male cyclists, with a maximal oxygen consumption of 76.0 (4.8) mL/min/kg, completed a three-week training camp, residing and training >1890 m above sea level. In the weeks following the altitude camp, cyclists were divided into two groups: one group exercised with a heat suit that limited heat loss for 50 minutes three times a week (n=9), while the other followed their usual training routine (n=9). Heat sessions are described in detail elsewhere [4]. The total Hbmass was measured before the altitude training camp, one day after the camp, and three weeks later, i.e., after heat/usual training. Inferential statements about differences in change scores between groups were based on analyses of covariance, with baseline values defined as covariate and the post values as dependent variable.

RESULTS: The three-week altitude training camp led to an overall increase in total Hbmass of 4.1 (2.5)%. The heat suit training group maintained their Hbmass for three weeks after the altitude training camp (0.2 (1.8)%), while the group of usual training displayed a reduction (-3.3 (0.8)%) in the same time period, which corresponded to a significant difference in Hbmass changes between groups during these three weeks ($p<0.05$).

CONCLUSION: Three weekly heat suit training sessions effectively preserved Hbmass compared to usual training without heat stimulation during the three weeks following an altitude training camp.

RACING DEMANDS FOR WINNING A GRAND TOUR: DIFFERENCES AND SIMILARITIES BETWEEN A FEMALE AND MALE WINNER

LAMBERTS, R., VAN VLEUTEN, A., DUMOULIN, T., VAN ERP, T.

STELLENBOSCH UNIVERSITY

INTRODUCTION: Professional road cycling is widely recognized as one of the most demanding sports, particularly during multi-day events such as Grand Tours. In the past decade, female professional cycling has experienced rapid growth, resulting in the introduction of two new Grand Tours, the Tour de France Femmes and the Vuelta Femenina. Despite evident disparities in the training (1) and racing habits (2) of female and male professional cyclists, less is known about the physical demands to win a Grand Tour.

METHODS: The power output of a female Grand Tour winner (Giro Rosa) and a male Grand Tour winner (Giro d'Italia) were analyzed. Mean maximal power outputs (MMP) during different stage types of the Grand Tour (e.g., time trials, flat, semi-mountainous, and mountain stages) were calculated. Additionally, relative power output (percentage of functional thresh-

old power (FTP)) was computed for both cyclists, as well as, time spent in different power zones and changes in MMP's with increasing levels of kJ burnt. A total of 64 power files were analyzed, while data was analyzed with independent t-tests and a one-way Analysis of Variance. Where needed, a Tukey post hoc tests was performed.

RESULTS: Differences in stage characteristics and absolute mean maximal power output were observed during all stage types ($p < 0.05$). However, similarities in relative power output (percentage of FTP) were found across all stage types (0.8-4.5%). Differences in percentage FTP power output were found during the first 50% of flat stages (14.7-15.1%) and the last 25% of mountain stages (9.8%). Overall, both cyclists had exceptionally high 20 to 60 minutes MMP values, reflecting their good climbing and excellent time trail capacities. Decrements in MMP's with increasing levels of kJ burnt were only observed from 30 kJ/kg in female cyclists and 45 kJ/kg in male cyclist.

CONCLUSION: This is the first study to provide insight into the racing demands of female and male cyclist, to win a Grand Tour. While expected differences were found in overall and stage characteristics, as well as absolute power output, strong similarities were found when power was expressed as a percentage of FTP power. The higher percentage of FTP power during the first half of flat stages and the last 25% of the mountain stages can likely be best explained by differences in racing tactics and potentially the climbing capacity of the two cyclists. Besides needing to be a good climber and time trial rider (high 20 to 20 MMP values (3,4)), the very late decrement of MMP's with increasing levels of kJ's burnt,5 highlights the importance of endurance and fatigue resistance in professional cyclists.

THE BONE QUALITY OF FEMALE ELITE CYCLISTS IS CHARACTERIZED BY IMPAIRED MICROARCHITECTURE OF CORTICAL AND TRABECULAR BONE AS ASSESSED BY HIGH-RESOLUTION PERIPHERAL COMPUTED TOMOGRAPHY (HR-PQCT)

HILKENS, L., VAN DEN BERGH, J., BEVERS, M., WYERS, C., VAN LOON, L., VAN DIJK, J.W.

HAN UNIVERSITY OF APPLIED SCIENCES

INTRODUCTION: Accumulating evidence indicates that many elite road-race cyclists have low areal bone mineral density (aBMD) as assessed by dual-energy X-ray absorptiometry (DXA). However, aBMD data does not provide information on bone quality, such as microstructural features of both cortical and trabecular bone, or bone strength. The present study aimed to assess aBMD, volumetric BMD (vBMD), bone microarchitecture, and bone strength in elite road-race cyclists.

METHODS: In this ongoing cross-sectional study, 20 female elite road-race cyclists (21±2 y; 59.8±6.1 kg; BMI 20.8±1.6 kg/m2) underwent DXA for the assessment of aBMD and high-resolution peripheral computed tomography (HR-pQCT) for the assessment of vBMD and bone microarchitectural parameters at the distal tibia and radius, respectively. Finite element analysis modelling was conducted to calculate bone strength. Z-scores were calculated for all outcomes, with Z-scores < -1 interpreted as low bone density or impaired bone microarchitecture. Data are presented as mean±SD and percentages.

RESULTS: With a mean Z-score of –0.3±0.9 and -0.9±1.1, low aBMD was present in 25 and 35% of the participants at the femoral neck and lumbar spine, respectively. Total vBMD of the tibia (296±39 mg/cm3) and radius (304±42 mg/cm3) was low in 40 and 45% of the participants, respectively. Low cortical vBMD was found in 35 and 40%, and low trabecular vBMD in 25 and 15% of the participants at the tibia and radius, respectively. At the tibia, 60% of the participants had a low cortical thickness (1.24±0.20 mm), 40% had low trabecular thickness (0.25±0.02 mm) and 30% had low trabecular number (1.33±0.19 trabeculae/mm). The findings at the distal radius were less pronounced, although 25% of the participants had a low cortical thickness. Calculated bone strength (failure load) was low in 20 and 15% of the participants at the tibia (8759±1522 N) and radius (3110±661 N), respectively.

CONCLUSION: Bone health of female elite road-race cyclists was characterized by low aBMD as measured by DXA, but also low vBMD as measured by HR-pQCT. The bone quality of elite road-race cyclists is particularly characterized by reduced cortical thickness and impaired trabecular microarchitecture at the tibia. Calculated bone strength was also affected, but to a lesser extent.

REDEFINING MUSCULAR ACTION: 3D ARCHITECTURAL ANALYSIS REVEALS HUMAN "ADDUCTOR" MAGNUS PRIMARILY ACTING FOR HIP "EXTENSION" RATHER THAN ADDUCTION IN VIVO

TAKAHASHI, K., TOZAWA, H., KAWAMA, R., WAKAHARA, T.
DOSHISHA UNIVERSITY

INTRODUCTION: Muscle mechanical action underpinning our movements is mostly determined by its architecture (1). The muscle architecture has been extensively examined in vivo by ultrasonography (2), but its use is limited to certain small muscles because of a limited field of view (3). We still poorly understand how giant muscles in the deep part of the body form and act in living humans. By a novel 3D architectural analysis based on MRI, we examined in-vivo architecture and the potential action of the human adductor magnus (AM), one of the giant leg muscles classified as a hip adductor. We hypothesized that the primary action of AM is hip "extension" rather than adduction, considering its configuration similar to hamstrings.

METHODS: For 14 healthy young adults (9 males), thousands of muscle fascicles were automatically reconstructed over the whole AM at the hip neutral position with diffusion tensor MRI and tractography (4,5). The muscle physiological cross-sectional area, and each fascicle's line of action and moment arm length about the hip joint were determined for the medial/proximal/lateral region divided based on insertion positions. Then, the product of these parameters was calculated as an estimate of the maximal isometric torque-generating capacity (potential torque: PT). The peak torque during maximal voluntary contraction for the isometric hip extension/adduction was measured at the hip neutral and 45° flexed positions on a dynamometer. The paired t-test and linear regression analyses were performed.

RESULTS: Most AM fascicles ran parallel to the femur, showing hamstring-like orientations in 3D. The proximal and lateral regions showed comparable PTs between the hip extension and adduction. In the medial region, however, the hip extension PT was 6-fold greater than the adduction PT ($p<0.01$). Consequently, the whole AM (sum of all regions) had a greater PT for the hip extension (42±15 Nm) than adduction (29±15 Nm, $p=0.02$). The hip extension PT of the whole AM was strongly correlated with dynamometer-measured hip extension peak torque at both hip neutral and flexed positions ($r=0.71–0.87$, $p\leq0.01$), but that was not the case for the hip adduction ($r=0.42–0.59$, $p\geq0.05$).

CONCLUSION: The results clearly indicate that AM primarily acts for hip extension rather than adduction, although it has been assumed a major adductor. The AM may thus play as a strong motor rather than a stabilizer in human locomotion such as sprint running demanding forceful hip extension. The present study redefining muscular action through the in-vivo 3D architectural analysis would motivate us to rename human muscles (e.g., "extensor" magnus) and rethink their functional role, providing novel insights into proper exercise selection for effectively improving motor performance in sports and rehabilitation.

EFFECT OF ECCENTRIC TRAINING AT DIFFERENT MUSCLE LENGTH ON MUSCLE-TENDON INTERACTIONS

TALLIO, T., NORDEZ, A., BIZET, B., CATTAGNI, T., DOREL, S.
NANTES UNIVERSITÉ

INTRODUCTION: Over the last 20 years, several studies showed that muscle-tendon interactions play a major role in movements (1). However, it remains unknown how the changes in muscle architecture due to training could influence these interactions. Eccentric studies have demonstrated an increase of the fascicle length following training in various muscles of the lower limb (2), and recently the benefits of training at high muscle length has been highlighted to induce more muscle adaptations, like hypertrophy or increase in fascicle length (3). Thus, the first aim of the current study is to investigate the potential change of fascicle behavior and tendon properties following an eccentric training at different muscle length. The second aim is to explore how these changes impact muscle-tendon interactions in vertical jump and running.

METHODS: 28 participants were randomised in two groups, High Length (HL) vs Short Length (SL). They performed 8 weeks (24 sessions) of eccentric training on the calf muscles at different range of motion (ROM). Measurements were made PRE and POST training. Fascicle length of the gastrocnemius medialis (GM) was measured with an ultrasound apparatus during maximal voluntary contractions (MVC) at 5 angles, eccentric contraction and through rate of force development (RFD) explosive contractions. We also estimated the stiffness of the Achilles tendon (AT) during ramp and RFD contractions. Finally, we measured the fascicle behavior of the GM during maximal vertical jumps (hopping and countermovement jump) and submaximal running.

RESULTS: We found a significant change of the fascicle length for HL group (+7%, p<0,05) during passive condition, but only before the slack length. No difference was found for the SL group. Torque increased in both groups in isometric (HL +8%, SL +13% at 0°, p<0,01) and eccentric contraction (HL +18,7%, SL +12,9%, p<0,01) but no interactions group x time were found. No significant change in fascicle length was observed during MVC, and no change in optimal length was detected in both groups. RFD did not change in both groups after training. AT Stiffness increased significantly for HL group (+29,9%, p<0,05) but not in SL group. Data from vertical jumps and running are still in processing.

CONCLUSION: No significant effects were found for fascicle-tendon interactions during maximal monoarticular contractions (RFD, MVC), suggesting that changes in muscle-tendon behavior (tendon stiffness and fascicle length) found in HL group does not impact the dynamic behavior of fascicles. We assume that these two factors offset each other's influence during contractions. Multi-joint maximal (jumps) and submaximal (running) tasks will provide a deeper understanding of the training effects on fascicle-tendon interactions.

SENSITIVITY OF JUMP-LANDING MOVEMENT CHARACTERISTICS TO ACL INJURY HISTORY AND FATIGUE.

MAITÉ, C., MOHR, M., FEDEROLF, P.

UNIVERSITY OF INNSBRUCK

INTRODUCTION: Return-to-sport (RTS) assessments often involve evaluations of movement execution, e.g. in jump landings, to identify deficits in movement control and connected risks for re-injury [1]. For RTS after anterior cruciate ligament (ACL) injury, the current literature offers a plethora of kinematic variables in various jump tests that clinicians may use to guide the RTS decision [1]. To better integrate RTS movement assessments in fast-paced clinical decision-making, it may be useful to investigate the most sensitive jump test and variable combinations for detecting movement deficits. The purpose of the current study was to compare the sensitivity of three commonly used jump tests for detecting movement characteristics influenced by either an ACL injury history, a provoked fatigue status, or a combination of both.

METHODS: A total of 43 volunteers were recruited into ACL group (n=21, 11 females) and control group (n=22, 12 females). 3D motion data (Vicon, 250 Hz) were recorded during a single-leg hop (SLH), unilateral counter movement jump (uCMJ) and a unilateral cross-over hop (COH) before and after a fatigue-inducing intervention (single-leg squats and step ups). Thirteen joint angles from lower body, trunk and pelvis (50ms after initial contact) representing the landing posture were calculated through inverse kinematics in OpenSim. One combined principal component (PC) analysis was computed for all three jumps to characterize kinematic synergies. Six distinct logistic regression models (three jumps, fatigued/non-fatigued, alpha = .05) were calculated to predict ACL injury history. Three additional models predicted fatigue status. The predictors consisted of twelve PC scores.

RESULTS: In all three jump landings, the logistic regression models were able to detect an ACL injury history (Chi^2= 4.974, p<.026) but not fatigue status (Chi^2=2.165, p>.141). When predicting ACL injury history, the highest sensitivity (76%) and classification rates (77%) were achieved for SLH (p<.001) and uCMJ (p<.001) when participants were fatigued. The worst sensitivity (67%) and classification (63%) was achieved for non-fatigued COH (p=.026). The SLH and uCMJ models consistently relied on the same two PCs, which described the correlation between frontal and transverse knee, hip and trunk angles.

CONCLUSION: In our data-driven analysis, the SLH and uCMJ appear more sensitive for detecting movement characteristics related to a previous ACL injury compared to the COH. Furthermore, our results support the recommendation to include fatigued conditions during RTS tests post-ACL injury [2]. The finding that our approach could not predict fatigue status could mean that (1) fatigue effects were non-systematic or (2) the between-subject variance in PC scores blurred smaller within-subject fatigue effects. Either way, the observation of an unsuccessful prediction makes it less likely that the classification by injury history was due to chance.

EVALUATION OF A PERSONALIZED ASSESSMENT AND LOADING CONCEPT TO REDUCE MUSCLE-TENDON IMBALANCES

DOMROES, T., WEIDLICH, K., BOHM, S., MERSMANN, F., ARAMPATZIS, A.

HUMBOLDT-UNIVERSITÄT ZU BERLIN

INTRODUCTION: Imbalances between muscle strength and tendon stiffness can increase the mechanical demand on the tendon (i.e., tendon strain) and tendon injury risk (1). The early identification of musculotendinous imbalances and accordingly adjusted training may thus contribute to tendon injury prevention (2). Therefore, the aim of the study was to identify muscle-tendon imbalances in athletes and promote a more balanced adaptation of muscle and tendon through a personalized assessment and loading concept.

METHODS: A total of 85 athletes (37 female and 26 male adolescents (13 – 16 yrs.), 22 male adults) were assigned to a control and intervention group. We assessed knee extensor muscle strength, patellar tendon stiffness and strain during

maximum isometric contractions (MVC) at four measurement time points during a competitive season. Muscle-tendon imbalances were identified based on the individual tendon strain during MVCs (2). In the intervention group, athletes with deficits in tendon stiffness (strain ≥9%) performed exercises (3x/week) with a personalized load to reach ~5.5% tendon strain to promote tendon adaptation, athletes with deficits in muscle strength (strain ≤4.5%) trained with submaximal loads to failure to mainly promote muscle strength. Linear mixed-effects models were used to analyze time- and group-dependent developments and the influence of sex and age.

RESULTS: We found lower fluctuations of maximum tendon strain ($p = 0.016$) and a decrease in the frequency of athletes with high-level tendon strain ≥9% in the intervention group. Normalized tendon stiffness and muscle strength increased significantly over time only in the intervention group ($p < 0.001$). These increases were more pronounced in male compared to female adolescents (sex by time by group interaction; $p = 0.010$ and 0.002). In adults we found a more pronounced increase in tendon strain in the control group compared to male adolescents (age by time interaction; $p = 0.040$) paralleled by a more pronounced increase in muscle strength (age by time by group interaction; $p = 0.010$).

CONCLUSION: The reduced fluctuations of maximum patellar tendon strain over the season and the lower prevalence of highly increased maximum tendon strain in both age groups and sexes indicate that the presented personalized concept was effective in reducing muscle-tendon imbalances and has the potential to contribute to tendon injury prevention, given the increased injury risk associated with high-level tendon strain. The smaller increases in muscle strength and tendon stiffness in females may suggest sex differences in muscle and tendon adaptation, which, however, did not affect the reductions in strain fluctuations and high-level tendon strain, and thus the effectiveness of the personalized concept.

PASSIVE HAMSTRING MUSCLES RIGIDITY CHANGES ALONG THE MENSTRUAL CYCLE FOR ANGLES RELATIVE TO THE KNEE RANGE OF MOTION.

BOUVIER, J., FOURÉ, A., MARTIN, C.

UNIVERSITE CLAUDE BERNARD LYON 1

INTRODUCTION: The menstrual cycle (MC) has recently been shown to affect the risk of muscle injury (1). Muscle strain injuries are thought to appear following active muscle lengthening (2), which highly involves muscle passive mechanical properties as previously reported (3). The aim of this study was to determine the impact of the MC on the passive hamstring muscles rigidity assessed with ultrasound shear wave elastography (SWE).

METHODS: Twenty-two eumenorrheic young active females attended three identical testing sessions during their early-follicular (EF), late-follicular (LF) and mid-luteal (ML) phases, confirmed by hormonal measurements. Knee was passively extended (2°/s) by an isokinetic dynamometer from 90° to 80% of the maximal joint range of motion (RoM), for a hip angle of 70° (hip and knee fully extended = 180°). Shear wave speed (SWS) was measured using SWE in the biceps femoris long head (BF), semitendinosus (ST) and semimembranosus (SM) during passive stretches. SWS and knee joint torque were assessed every 10% of each participant's RoM and every 10° of absolute knee angle (from 90° to 80% ROM or 120° [i.e., maximal common knee angle for the entire experimental population]). Linear mixed models were used to investigate the effect of the MC phase on maximal knee RoM, knee joint torque and on each passive hamstring muscle SWS. Post-hoc analysis was conducted using Tukey HSD test when appropriate.

RESULTS: Maximal knee RoM remained consistent along the MC ($P=0.22$). The knee joint torque expressed relatively to each participant's RoM was greater during EF and LF phases than during ML phase ($P<0.001$), while it did not differ throughout the MC for absolute knee joint angles ($P=0.43$). The SWS expressed relatively to each participant's RoM was greater during the ML phase than during EF and LF phases in the BF ($P<0.01$), while it was greater during the EF and LF phases than during the ML phase in the ST ($P<0.01$). On the opposite, the SWS expressed in absolute knee joint angles did not differ along the MC ($P=0.27$, 0.07 and 0.47 for BF, ST and SM, respectively).

CONCLUSION: When rigidity was expressed in function of absolute knee angles, no difference was observed along the MC. However, for angles relative to individual RoM, BF rigidity was at its highest point during the ML phase, while the ST one was at its lowest. Interestingly, the risk of muscle injury has been shown to be greater in the ML phase and the BF is the most injured hamstring muscle (1,4). While muscle rigidity has been correlated to markers of exercise-induced muscle damage (5), the link between muscle injury occurence and a potential modulation of hamstring muscles rigidity by the MC has to be further assessed.

Invited Symposium

IS-PN03 Lipid droplets and mitochondria: The importance of a functional, dynamic relationship for metabolic health

LIPID DROPLET DYNAMICS IN HEALTH AND DISEASE

BARRETT, J.
LIVERPOOL JOHN MOORES UNIVERSITY

The aim of this talk is to present the current knowledge on how LD proteins respond to exercise training and their role(s) in regulating intramuscular triglyceride (IMTG) storage and utilisation during exercise. Our previous studies using immunofluorescence microscopy demonstrated that the expression of the LD-associated perilipin (PLIN) proteins are sensitive to a variety of exercise training types. Importantly, in healthy individuals at least, the expression of the PLIN proteins is closely aligned to IMTG content, and this relationship has implications for the regulation of the IMTG pool. In this context, this presentation will highlight the potential regulatory roles for the PLIN proteins in mediating IMTG storage and IMTG utilisation during exercise. This will include recent and new insights from studies employing time-course designs to reveal several important roles for the PLIN proteins contributing to the dynamic nature of LDs. Furthermore, these studies have also generated evidence that the PLIN proteins themselves are also dynamic, providing additional intrigue into the regulation of these proteins and directions for future work.

IS SKELETAL MUSCLE MITOCHONDRIAL CAPACITY IMPAIRED IN INDIVIDUALS WITH INSULIN RESISTANCE AND TYPE 2 DIABETES?

WHYTOCK, K.
LIVERPOOL JOHN MOORES UNIVERSITY

Impaired mitochondrial capacity has historically been linked to the development of insulin resistance (IR) in skeletal muscle (SkM); however this association remains controversial. Discrepancies in the literature may partially be attributed to the techniques employed to measure SkM mitochondrial capacities (enzymatic activities, ex vivo respiration, and in vivo ATP max/PCr recovery rates) and phenotypic differences (aerobic capacity, body mass index (BMI), and age) among the cohorts analyzed that are known to affect mitochondrial capacity. This talk will explore whether mitochondrial capacity is impaired in individuals with IR and T2D when confounding factors of age, BMI and aerobic capacity are accounted for and using an in-depth comprehensive suite of analyses including; in vivo PCr recovery, ex vivo mitochondrial respiration, supercomplex assembly, tricarboxylic acid (TCA) cycle intermediates, citrate synthase activity, transcriptomics and methylomics. Lastly, this talk will highlight the transcriptional and methylation profiles that underpin SkM IR that are not related to mitochondrial capacity and show whether these molecular profiles are retained in vitro in differentiated primary human skeletal muscle cells.

THE DYNAMIC INTERACTION BETWEEN MITOCHONDRIA AND LIPID DROPLETS IN HEALTH AND DISEASE.

GEMMINK, A.
MAASTRICHT UNIVERSITY

Skeletal muscle represents a tissue with high plasticity, both structurally and metabolically. Muscle can readily adapt to fluctuations in energy demand and nutrient (substrate) availability. Thus, skeletal muscle (mal)adapts to longer periods of unloading and loading, but also to dynamically adapts to microcycles in energy demand and supply. Our lab is specifically interested into the dynamics in fuel storage and oxidation in skeletal muscle, the subcellular organelles involved and their spatial (re)orientation and interaction. Thus, we have studied dynamics in lipid droplet synthesis and degradation, mitochondrial network dynamics and interaction of lipid droplets with mitochondria and vice versa. We study these phenomena in humans over the entire range of energy expenditure, i.e. in obese sedentary individuals and in elite athletes. We also link this to read-outs of metabolic health and physical fitness. To this end, we use a variety of whole-body measurements of metabolic health and performance all the way down to super resolution microscopy to image and quantify dynamic processes of (a cluster of) molecules and organelles involved in lipid droplet en mitochondrial networks. Physical exercise and nutrient intake/deprivation are strong triggers to modulate lipid droplet and mitochondrial dynamics. In the presentation we will discuss how transient energy gaps, generated by exercise or short-term food deprivation, affect mitochondrial and lipid droplet interaction and if and how these dynamics are determinants of health and performance.

Invited Symposium

IS-SH02 Intentional and unintentional doping: what is the risk of using dietary supplements?

CROSS-CONTAMINATION OF DIETARY SUPPLEMENTS: WHAT PREVENTS ATHLETES FROM UNINTENTIONALLY DOPING?

MUROFUSHI, Y.
JUNTENDO UNIVERSITY

Dietary supplement users are at an increased risk of unintentionally doping than non-users. A body of evidence has shown that due to issues with manufacturing, dietary supplements can become cross-contaminated with substances that are prohibited for use in sport. In fact, reports from the Court of Arbitration for Sport indicate that 45% of athletes who failed a drug test, were attributed to the use of a dietary supplement that had become contaminated with a prohibited substance. Despite athletes being aware of the risks associated with cross-contamination and having received education to ensure the supplements they take have been batch tested (i.e., contain no prohibited substances), athletes continue to use supplements to facilitate their performance. While evidence for the occurrence of cross-contamination is well-established, a paucity of research exists for why athletes choose to use a dietary supplement when a significant unintentional doping risk is present. To help anti-doping organisations develop more effective education interventions and target factors that prevent unintentional doping, a need exists in understanding the psychological reasons for that best protect an athlete from using a dietary supplement. In the anti-doping psychosocial science literature, a number of factors have been identified to be related to doping. Athlete's beliefs that dietary supplements are effective has consistently been shown to be related to both dietary supplement use and doping. That is, athletes that use dietary supplements are more likely to believe that they are effective and in turn, use prohibited substances. However, no research has considered whether athletes are aware that dietary supplements can be contaminated and if this in turn, influences their beliefs and use of dietary supplements. The aims of the presentation are to explain the role of dietary supplement beliefs in the decision to use performance enhancing substances, and how awareness of the risk of cross-contamination may influence the relationship between dietary supplement beliefs and use. A theoretical model will be posited before highlighting empirical cross-sectional research on the relationship between awareness of cross-contamination, dietary supplement beliefs and use. Finally, the speaker will highlight how anti-doping organisations can use results of this data to develop more effective education interventions that foster better understanding of the risks associated with dietary supplements and unintentional doping.

DIETARY SUPPLEMENT USE AND INTENTIONAL DOPING: WHAT DOES THE EVIDENCE SUGGEST?

HURST, P.
CANTERBURY CHRIST CHURCH UNIVERSITY

For over 20 years, researchers have recognised that those who use dietary supplements are more likely to use prohibited performance enhancing substances. Reasons for this are suggested to relate to athletes normalising the use of performance enhancing methods and over time, progressing to doping for equal or better performance improvements. That is, an athlete who uses a dietary supplement is suggested to become comfortable with using these substances to improve performance, normalise the practice of using performance enhancing substances, and over -time seeks out stronger and more potent substances to achieve similar or better results. However while a number of individual studies have examined the phenomena, a need exists in summarising and synthesising the extant literature to help identify the relative risk dietary supplement use has on intentional doping. To help improve precision and understanding of the risk dietary supplement use has on doping, in this presentation, the speaker will report the results of a systematic review and meta-analysis of studies examining the relationship between dietary supplement use and doping. Briefly, the speaker will highlight that from 23 studies including 8,822 athletes, dietary supplement users are over 2.5 (Odds ratio = 2.77, 95% CI = 2.10 to 3.57) times more likely to dope and have a greater intention (pooled r = 0.26, 95% CI = 0.18 to 0.34) and more favourable attitude (pooled r = 0.20, 95% CI = 0.13 to 0.28) to dope than non-users. Reasons for why dietary supplement users progress to prohibited substance use will be described and the psychosocial factors that anti-doping educators can use in their interventions to best protect dietary supplement users from doping will be explained. The speaker will also highlight the practical implications for athlete practitioners (e.g., coaches, nutritionists, physiotherapists) aiming to prevent their athletes from intentionally doping after using a dietary supplement.

FREQUENCY AND TYPES OF DIETARY SUPPLEMENTS: DO ALL SUPPLEMENTS LEAD TO UNINTENTIONAL AND INTENTIONAL DOPING?

GARCÍA-GRIMAU, E.
UNIVERSIDAD AUTÓNOMA DE MADRID

In the previous two presentations, dietary supplement use has shown to be a risk for both intentional and unintentional doping. While the research underpinning both presentations highlight the significant risk athletes may be exposing themselves to when using a dietary supplement, evidence is limited in that it does not consider the frequency and types of dietary supplements used. That is, researchers assessing the relationship between dietary supplement use and intentional doping often group all types of dietary supplement users together and do not quantify how often an athlete uses the

supplements. Arguably, an athlete using an electrolyte sports drink once to remain hydrated during a competition is less likely to dope than another using a pre-workout supplement daily to gain a competitive advantage. Understanding whether certain supplements pose a greater risk to unintentional and intentional doping is important given that prevelance of dietary supplement use is estimated at over 60% and many athletes will look to seek out ways in which they can facilitate their performance. To help athletes and practitioners identify which supplements are more likely to increase the risk of intentional and unintentional doping, a need exists in examining the relationship between frequency of use and likelihood to dope and identifying the supplements that are more likely to be cross-contaminated and cause unintentional doping. The aim of this presentation is to provide data on the frequency and types of dietary supplement used in relation to the likelihood to intentionally dope and critically review evidence of the substances that athletes may use that could lead to unintentional doping. The speaker will highlight that athletes who use ergogenic and medical supplements daily, are at an increased risk of doping intentionally than those who use sport foods and drinks sparingly. Afterwards, a comprehensive review of studies examining cross-contamination in supplements will be given, which reports multi-ingredient, pre-workout, and muscle-building supplements (e.g., protein shakes) as the greatest risk for cross-contamination, and reasons for why this occurs will be discussed. To help best protect athletes from both unintentional and intentional doping, the speaker will provide recommendations on how athletes and practitioners can recognise the risks of certain types of supplements and offer alternative methods in which they can achieve their goals.

MUSCLE DAMAGE AND REPEATED BOUT EFFECT FOLLOWING A TYPICAL DOSE OF NORDIC HAMSTRINGS EXERCISE

CORATELLA, G., LONGO, S., DORLANDO, A., STERI, E., LA SPINA, O., MOCCHI, C., CÈ, E., ESPOSITO, F.
UNIVERSITÀ DEGLI STUDI DI MILANO

INTRODUCTION: Nordic hamstrings exercise provides lengthening stimuli to the hamstrings with the intent to increase their resistive capacity to overstretching. While many longitudinal studies have found the effectiveness of NHE in increasing hamstrings strength and in elongating fascicles, the incorporation of NHE in the practice requires a deeper examination given the short-term effects due to the eccentric stimuli. Therefore, the present study investigated the exercises-induced muscle damage and the repeated-bout effect following a typical dose of NHE.

METHODS: Thirteen active men (mean±SD; age=25.2±2.9 years; body mass=77.5±11.3 kg; height=176.4±8.4 cm) were recruited. Hamstrings eccentric strength, muscle soreness, passive range of motion (ROM), anatomical cross-sectional area and echo-intensity of biceps femoris, semitendinosus and semimembranosus were assessed at baseline, and up to four days after the NHE bout. The repeated-bout effect was examined after four weeks by repeating the same procedures. NHE session consisted of 4 x 6 repetitions. A two-way repeated-measures ANOVA as statistical analysis.

RESULTS: After the first bout, hamstrings eccentric strength decreased and remained below the baseline up to three days (average loss: □-25%, mean Cohen's d effect size [ES] ranging from -3.88 to -2.95, $p<0.05$); muscle soreness increased two days after and remained higher up to four days (mean ES ranging from 1.30 to 1.62, $p<0.05$); passive ROM decreased up to four days (mean ES ranging from 0.64 to 1.62, $p<0.05$); anatomical cross-sectional area and echo intensity did not show any changes, both for the separate and combined muscles ($p>0.05$ for all comparisons). After the second bout, hamstrings eccentric strength decreased and remained below baseline up to one day (-22.5%, ES: -1.79, $p<0.05$); muscle soreness did not increase; passive ROM decreased up to two days (mean ES -ranging from -0.85 to -0.77); no change occurred in cross-sectional area and echo intensity.

CONCLUSION: A typical dose of NHE showed impairments in muscle function but did not affect muscle structure. The current data offer novel perspectives on incorporating NHE into the weekly routine, since defining the recovery time course after a typical NHE dose. Additionally, the recovery after the second bout is much faster. In the practice, a first bout of NHE is suggested to be included far from competitions or a congested training routine, while a second bout can be safely incorporated without any meaningful impairments in the following days.

SYNERGISTIC EFFECTS OF RESISTANCE TRAINING AT MODERATE ALTITUDE ON METABOLIC-RELATED MYOKINES: IMPLICATIONS FOR ADIPOSE TISSUE MODULATION

PEREZ REGALADO, S., LEON, J., BENAVENTE, C., BONITCH-GONGORA, J., ALMEIDA, F., PADIAL, P., DE LA FUENTE, B., GIL-GUTIERREZ, R., FERICHE, B.
UNIVERSITY OF GRANADA

INTRODUCTION: Hypobaric hypoxia (HH) exposure is characterized by an elevation of the sympathetic nervous system that could impact on metabolic-related myokines in human adipocytes, such as interleukin 15 (IL-15), involved mainly in the promotion of lipolysis (1). Additionally, resistance training (RT) programs have been associated with weight loss while preserving muscle mass. However, there are no previous studies undertaken long-term RT regimens under terrestrial HH conditions describing the molecular mechanisms linked to modulation of subcutaneous adipose tissue (SAT) thickness. In this sense, the present study aims to analyse the influence of HH exposure on SAT and circulating IL-15 response after an 8-week RT program.

METHODS: Twenty men (22.75±3.73 years; 176.4±5.93 cm; 73.01±10.97 kg) participated in an 8-week program (3 sessions/week) of a traditional hypertrophy training under intermittent terrestrial HH (2320 m) or normoxia (N, 690 m). Seventy-two hours before and after the RT program, vastus lateralis (VL) thickness and SAT were measured by ultrasound (GE-LOGICQ-E portable, UK) and blood samples were taken to analyse serum IL-15 by immunology multiplex assay (Sigma-Aldrich; Darmstadt, Germany).

RESULTS: Circulating IL-15 revealed an environmental effect following 8 weeks of RT program ($F_{1,18} = 4.399$; $p = 0.050$; $n2p = 0.196$). The pairwise comparison test revealed that HH after RT tend to be favour IL-15 increase (ES = 0.890; $p = 0.062$) compared to N. Moreover, SAT displayed a very large decrease in HH after the RT period (11.56 % vs -17.69 % in N and HH; $p < 0.001$ [ES = -1.92]) with no remarkable change in VL between conditions ($p > 0.05$).

CONCLUSION: These results evidence the effect of RT in HH on SAT and serum IL-15 with respect to the same training in N. This effect could be attributed to the IL-15 upregulation-induced muscle promotion of the fibber switching to type II and in the overall increase of lean mass ratio by the stress of the HH combined with RT. (2). Surprisingly, VL values were maintained without significant changes between conditions. Nonetheless, this outcome may not represent the entire effect on muscle growth on muscle due to a potential heterogeneous growth of the vastus quadriceps due to the orientation of the feet during squat training (3). Thus, taking all results together, it appears that the stressors factors linked to RT in HH may play a key role in the overall body composition. Further research targeting this potential non-pharmacological approach for adipose regulation is needed to determine the implication on sport performance and control of obesity-related disorders.

A COMPARISON OF FLYWHEEL CLUSTER SET TRAINING AND TRADITIONAL CLUSTER SET RESISTANCE TRAINING OVER 8-WEEKS ON ATHLETIC PERFORMANCE IN TEAM SPORT ATHLETES.

RYAN, S., RAMIREZ-CAMPILLO, R., BROWNE, D., MOODY, J., BYRNE, P.J.

SOUTH EAST TECHNOLOGICAL UNIVERSITY CARLOW

INTRODUCTION: The correlation between effective resistance training programmes and success in team sports is widely agreed upon due to the physical demands placed upon athletes. As performance demands increase, the implementation of innovative resistance training strategies ensue. Cluster training has gained popularity, through its use of "intra-set" rest periods, proven to benefit training volume, power outputs and fatigue accumulation. Although, to date there is a scarcity of research integrating the cluster model during flywheel (FW) training. Thus, the purpose of this study was to compare the effect of flywheel cluster set training (FWC) and traditional cluster set resistance training (TDC) on athletic performance in team sport athletes.

METHODS: Seventy-six amateur male field sport athletes participated in this study during the pre-season phase of their training calendar. Participants were randomly allocated into one of three groups; FWC, TDC or a control (CON) group. All participants underwent pre and post intervention testing for 20m linear sprints, countermovement jumps (CMJ), 5-10-5 change of direction (COD) and 3RM lower body strength. During the 8- week intervention, both FWC and TDC groups performed two sessions per week, consisting of 4 sets of 9 repetitions using quarter-squats and Romanian deadlifts. Intra-set rest durations of 45 seconds were allocated between cluster blocks [1]. The FWC group used the 0.050kg.m2 inertial load, while the TDC group used 70% of their predetermined 1RM for the initial 4-weeks, followed by increasing the load to 75% for the final 4-weeks. The CON group were instructed to performed pitch sessions only.

RESULTS: Both cluster training groups reported similar group x time interactions with significant improvements between pre and post testing results in all performance exercises. The Hex-bar deadlift reported improvements ($p < 0.05$) in lower body 3RM strength in the FWC group (ES = 0.40, PC = 6.91%) and for the TDC group (ES = 0.38, PC = 7.06%). Moreover, improvements in sprint performance ($p < 0.001$) were reported in both 5m (FWC- 3.14%, TDC- 2.62%) and 20m linear sprint speed (FWC- 1.89%, TDC- 1.04%). While ES indicated that COD saw the largest increase in performance (FWC- 0.93- 1.12, TDC- 0.96- 0.98). Furthermore, COD reported significant improvements ($p < 0.05$) on both right and left lateral turns (FWC- 5.64- 6.55%, TDC- 5.39- 6.05%). Lastly, the CON group reported trivial changes throughout all tests post intervention.

CONCLUSION: This is the first study to compare a flywheel cluster training block to a traditional barbell cluster training block. The similarity of results and increases to performance parameters indicate the usability of both training methods. These findings should encourage coaches and sport science practitioners to utilize both training methods within resistance training programmes to increase field sport athlete performance.

INTENSITY OF SIX ECCENTRIC CONTRACTIONS PERFORMED 5 DAYS A WEEK FOR 4 WEEKS TO INCREASE MUSCLE STRENGTH AND VOLUME

NOSAKA, K., YOSHIDA, R.1, MURAKAMI, Y.2, KASAHARA, K.2, SATO, S.3, NAKAMURA, M.4

EDITH COWAN UNIVERSITY, 1 MANIWA ORTHOPEDICS CLINIC, 2 NIIGATA UNIVERSITY OF HEALTH AND WELFARE, 3 MATSU-MURA GENERAL HOSPITAL, 4 NISHI KYUSHU UNIVERSITY

INTRODUCTION: We reported that one 3-s maximal eccentric contraction of the elbow flexors performed on an isokinetic dynamometer 5 days a week for 4 weeks increased maximal voluntary isometric (MVC-ISO), concentric (MVC-CON), and eccentric contraction (MVC-ECC) torque of the elbow flexors by 10.2±6.4%, 12.8±9.6% and 12.2±7.8%, respectively [Sato et al. Scand J Med Sci Sports. 32:833-43, 2022]. However, these effects were not produced by one 3-s maximal isometric nor concentric contraction in the same format. Our other study showed that daily six maximal eccentric contractions that were performed on an isokinetic dynamometer 5 days a week for 4 weeks increased MVC-ISO (9.3±5.5%), MVC-CON (11.1±7.4%), and MVC-ECC torque of the elbow flexors (13.5±11.5%), and muscle thickness (MT) of biceps brachii and brachialis (10.4±4.4%) [Yoshida et al. Scand J Med Sci Sports. 32:1602-14, 2022.]. To perform maximal eccentric contraction(s), a specific device such as an isokinetic dynamometer is necessary, which is difficult to be accessed practically. The present study examined whether the muscle strength and MT would still be increased when a dumbbell was used with the training intensity of six eccentric contractions being reduced to 2/3 or 1/3 of the peak MVC-ECC torque.

METHODS: Thirty-six healthy young (19-24 y) adults who had not performed resistance training were placed to three groups (n=12/group): 2/3MVC or 1/3MVC that performed the six eccentric contractions with a dumbbell set at 2/3 or 1/3 MVC-ECC load 5 days a week or control group that did not perform any training for 4 weeks. Changes in MVC-ISO, MVC-CON, MVC-ECC torque of the elbow flexors, and MT before and after the 4-week period were compared among the groups and with the group of the previous study [Yoshida et al. Scand J Med Sci Sports. 2022.] in which six maximal eccentric contractions were performed 5 days a week for 4 weeks (MVC group; n=12) by two-way repeated measured ANOVA.

RESULTS: All participants reported to the laboratory to perform the training without any missing sessions. The control and 1/3MVC groups showed no significant changes in any measures. Significant ($p<0.05$) increases in MVC-ISO (10.3±11.4%), MVC-CON (10.9±9.5%), and MVC-ECC (9.3±8.8%) torque and MT (10.1±9.2%) were observed for the 2/3MVC group. When comparing the 2/3 MVC and MVC groups, no significant differences in the changes in the measures were found. This may be due to that the dumbbell set at 2/3 of MVC-ECC torque was close to the MVC-ECC at elbow extended angles.

CONCLUSION: These results suggest that submaximal-intensity at 2/3 MVC-ECC is still effective for the six maximal eccentric contractions to increase muscle strength and MT, and the "submaximal" intensity using a dumbbell produced the same effects as those by maximal intensity protocol using an isokinetic dynamometer. The present study together with the previous studies show potent effects of daily small volume eccentric contractions on muscle adaptations, which could be used in practice.

OP-PN16 Hypoxia II

EFFECT OF ACUTE NORMOBARIC HYPOXIA ON WHOLE-BODY FAT OXIDATION KINETICS AT MATCHED RELATIVE INTENSITIES COMPARED TO NORMOXIA: INTENSITY MATTERS!

GARCIA, J., ALLENDER, P.1, BROCHERIE, F.2, MALATESTA, D.1

1 UNIVERSITY OF LAUSANNE, SWITZERLAND, 2 FRENCH INSTITUTE OF SPORT , FRANCE

INTRODUCTION: The heterogeneity of the effects of acute hypoxia on substrate oxidation during exercise matched for relative intensity compared with normoxia (N) has been previously reported [1]. While fat oxidation kinetics over a wide range of intensities in N has already been well described [2, 3], the homologous kinetics in normobaric hypoxia (NH) and its comparison at identical relative intensities with N are unknown. Therefore, this study aimed to investigate the effect of acute NH vs. N on whole-body fat oxidation kinetics at identical relative intensities during a submaximal graded cycling test.

METHODS: Thirteen active men (24.9±3.0 yrs) performed i) two maximal incremental cycling tests to determine maximal oxygen uptake (VO2max) in either NH [hypoxic chamber; inspired fraction of oxygen (FiO2) = 12.7%, ~4000 m] or N [FiO2 = 20.7%, ~375 m], and ii) two submaximal graded cycling tests to assess whole-body fat oxidation in each condition, using indirect calorimetry after an overnight fast and 20-min acclimation to NH. A sinusoidal model was used to characterize, with three independent parameters (dilatation, symmetry and translation), the whole-body fat oxidation kinetics and to determine Fatmax [i.e., the intensity eliciting the maximal fat oxidation (MFO)] in both conditions [2].

RESULTS: VO2max was significantly lower (50.4±5.3 vs. 61.5±7.5 ml/kg/min, $p<0.001$) and Fatmax was significantly higher (63.9±6.7 vs. 57.7±4.3 %VO2max, $p<0.001$) in NH vs. N. MFO (0.66±0.22 vs. 0.49±0.12 g/min, $p=0.005$) and whole-body fat oxidation rates for exercise intensities ranging from 50 to 85% VO2max ($p<0.019$) were significantly higher in NH vs. N. The mean kinetics in NH was characterized by a significantly greater dilatation (widening of the curve, $p=0.01$) with no significant difference for symmetry ($p=0.17$) and translation ($p=0.79$) vs. N.

CONCLUSION: Whole-body fat oxidation kinetics differed between normobaric hypoxia and normoxia when compared at the same relative exercise intensities, with greater dilatation, MFO, Fatmax and fat oxidation rates during moderate- and high-intensity exercises in normobaric hypoxia. Exercise intensity may thus play a central role in the effect of hypoxia on fat oxidation, confirming previous findings involving carbohydrate intake [4]. For the same relative moderate- to high-intensity exercise, the greater reliance on fat oxidation in normobaric hypoxia vs. normoxia seems consistent with the increased oxidation of plasma non-esterified fatty acids, representing a more important part of total fat oxidation during moderate- to high-intensity exercise. The present findings support that acute exposure to normobaric hypoxia vs. normoxia after overnight fasting enhances the metabolic pathways of fat oxidation during moderate- to high-intensity exercise.

EFFECT OF ACUTE NORMOBARIC HYPOXIA ON COGNITIVE PERFORMANCE AND CEREBRAL OXYGENATION IN YOUNG HEALTHY SUBJECTS

FAUCHER, C., MATHE, N., SAULNIER, P.J., MAQUA, A., THEUROT, D., BOULARES, A., GIMENES, M., DUGUE, B., PICHON, A., DUPUY, O.

UNIVERSITY OF POITIERS - CHU POITIERS

INTRODUCTION: The association between cerebral oxygen level and cognitive function is extensively documented in the normal oxygen range. However, the heterogeneity in protocols designed to investigate the impact of hypoxia-induced changes in cognitive function prevents definitive conclusions regarding underlying mechanisms of cognitive performance. In this study, we aimed to assess the effect of acute normobaric hypoxic conditions on cognitive functions and cerebral oxygenation.

METHODS: We enrolled healthy participants aged 18 to 30 in a crossover study to explore the effects of 4 simulated altitudes on executive function. These altitudes included normoxia at sea level (SL; FiO2: 21%), low hypoxia (1600 m altitude; FiO2:17.2%), moderate hypoxia (3000 m altitude; FiO2:14.4%), and high hypoxia (4100 m altitude; FiO2:12.5%). Executive function was assessed using 4 standardized cognitive tasks: Stroop task, N-Back, Corsi blocks, and Go/No-Go. The sequence of cognitive tasks and altitude conditions were randomized. Peripheral oxygen saturation (SpO2) and heart rate (HR) were continuously monitored. Cerebral oxygenation was measured using near-infrared spectroscopy during each condition. Changes in the tissue saturation index (ΔTSI%), total hemoglobin (ΔtHb), deoxyhemoglobin (ΔHHb), and oxyhemoglobin (ΔO2Hb) were defined as the difference between each hypoxia level and the normoxia resting state. Perceived exertion after each task was assessed using the DP15 rating scale.

RESULTS: In 23 participants (22.2±2.8 years; 11 females and 12 males), SpO2 decreased with increasing hypoxia dose, and each condition was different from the others ($p<0.001$). There was a significant association between perceived exertion level after the Stroop task and hypoxic level ($p=0.003$) but not after the other 3 cognitive tasks ($p=0.098$ to 0.977). The hypoxia was only statistically associated with accuracy during the Stroop task (the higher the hypoxia, the higher the mean error rate during the task; $p=0.039$) but not with other tasks. No significant change in tissue saturation and total hemoglobin (ΔTSI% and (ΔtHb) were found. However, there was a statistically significant increase in deoxyhemoglobin values (ΔHHb) and a significant decrease in oxyhemoglobin (ΔO2Hb) for every cognitive task with the severity of hypoxia.

CONCLUSION: In summary, our findings suggest that only severe acute normobaric hypoxia impacts executive functions in young healthy subjects. This modest effect may be partially due to compensatory mechanisms operating at the cerebral oxygen extraction level. Nevertheless, participants reported a progressively increased in the perception of task difficulty under all progressive hypoxia levels during every demanding task suggesting a larger cognitive cost.

COMPARISON OF NORMOBARIC HYPOXIA STRATEGIES ON STRENGTH PERFORMANCE

JIMÉNEZ, J.A., FERICHE, B., PÉREZ-REGALADO, S., BENAVENTE, C., PADIAL, P., GARCÍA RODRÍGUEZ, S., TIMÓN, R.

UNIVERSITY OF EXTREMADURA

INTRODUCTION: Acute exercise under hypoxic conditions induces a drop in blood oxygen levels (hypoxemia) and impact in continuous oxygen supply to tissues (1). Terrestrial altitude presents a logistical challenge. For this reason, certain research endeavours to replicate high-altitude scenarios within normobaric hypoxia (NH) (2). However, one of the main concerns in using NH systems is the accumulation of CO2 levels and increased temperature and humidity inside the tent resulting from athletes' exhalation (3). Therefore, combining reduced oxygen availability and increased environmental stressors could affect performance (4). The present study aims to analyse the effects of a resistance training (RT) period under two different NH environment emplacements on strength development.

METHODS: Nineteen men (22,16 ± 2,94 years; 176,79 ± 7,47 cm; 76,32 ± 11,00 kg) participated in an 8-week- hypertrophy RT program (3 sessions /week) under systemic moderate NH (FiO2 = 15,9%) in a tent (8 m2; 50 l/min/persona) or in a room (60 m2; 900 l/min/persona). Before and after the program, one repetition maximum (1RM) in back squat and bench press exercises were evaluated. Maximal blood lactate and rating of perceived exertion (RPE min25) were also measured after the programs first and last sessions. Environmental CO2 was monitored during the RT sessions.

RESULTS: The values of change in CO2 concentration from the beginning to the end of the session were significantly higher in the tent (4947,70 ± 1918,84 ppm) compared with the room (550,31 ± 405,40 ppm). 1RM increased in both groups ($p < 0.05$), with no differences between groups ($p > 0.05$). No differences were found in the RPE and lactate between conditions ($p > 0.05$).

CONCLUSION: Results reveal a strength development after a RT period in NH regardless of the environmental additional stressors. However, such a higher CO2 concentration measured in the NH tent could lead to a greater physiological strain during exercise, impacting the normal functioning of organic systems not evaluated in this study. Therefore, the type of equipment used must be considered when conducting NH training.

ADDING A SUSTAINED ATTENTION TASK TO A PHYSICALLY DEMANDING CYCLING EXERCISE EXACERBATES NEUROMUSCULAR FATIGUE AND IMPAIRS COGNITIVE PERFORMANCE IN BOTH NORMOXIA AND HYPOXIA.

GOEPP, T., HAYES, M., DI DOMENICO, H., HOT, P., RUPP, T.

UNIVERSITÉ SAVOIE MONT BLANC

INTRODUCTION: Both cognitive motor dual-tasks (CMDT) protocols and hypoxic environments have been associated to significant impairments on cognitive and physical performances. We aimed to determine the effects of hypoxia on cognitive performance and neuromuscular fatigue during a highly physically demanding CMDT.

METHODS: Fifteen young adults randomly participated in a separated task session in normoxia (CTLEX, CTLCOG) and in CMDT sessions in normoxia (DTNOR) and hypoxia (DTHYP). The physical exercise consisted of 20 min cycling at an "hard" perceived effort, and the cognitive task consisted of 15 min sustained attention to response time task (SART). Concurrent psycho-physiological measurements included: quadriceps neuromuscular fatigue (peripheral/central components from femoral nerve electrostimulation), prefrontal cortex (PFC) oxygenation by near-infrared spectroscopy, and perception of effort.

RESULTS: SART performance significantly decreased in DTNOR (-15.7±15.6%, $P<0.01$) and DTHYP (-26.2±16.0%, $P<0.01$) compared to CTLCOG (-1.0±17.7%, $P=0.61$). Peripheral fatigue similarly increased across conditions, whereas the ability of the central nervous system to activate the working muscles was impaired similarly in DTNOR (-6.1±5.9%, $P<0.001$) and DTHYP (-5.4±7.3%, $P<0.001$) compared to CTLEX (-1.1±0.2%, $P=0.52$). Exercise-induced perception of effort increased in DTHYP (+1.1±0.2, $P<0.001$) and in DTNOR (+0.7±0.2, $P=0.001$), while CTLEX remained unchanged (+0.4±0.2, $P=0.42$). This was correlated with cognitive impairments in both normoxia ($r=0.64$, $P=0.01$) and hypoxia ($r=0.53$, $P<0.05$). PFC deoxygenation was more pronounced in DTHYP compared to DTNOR (-6.9±1.7%, $P<0.001$) and CTLEX (-7.6±1.7%, $P<0.001$).

CONCLUSION: In conclusion, performing a sustained attention task together with physically challenging whole-body exercise promotes central neuromuscular fatigue and impairs cognitive accuracy; the latter is particularly noticeable when the CMDT is performed in hypoxia.

EFFECT OF STRENUOUS EXERCISE SESSION UNDER HYPOXIA ON SLEEP QUALITY IN YOUNG MALES.

MATSUDO, H., GOTO, K.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Sleep is an indispensable activity to maintain health. Insufficient sleep duration or decreased sleep quality has been associated with an increased risk of injuries and augmented inflammation (Milewski et al., 2014). Previous research has revealed that sleep quality tends to be decreased during sleep in hypoxia compared with sleep in normoxia (Heinzer et al., 2016). However, typical type of "living low, training high" procedure involves exercise in hypoxia (< 2h) and sleep in normoxia. Therefore, further investigations need to clarify how high-intensity exercise under hypoxia affects sleep quality. The present study was designed to clarify the effect of strenuous exercise session under hypoxia on sleep-related physiological responses in young

METHODS: Ten healthy active males(20.3±0.4year, 172.7±1.8cm, 65.29±2.1kg) were recruited. They performed 3 conditions on different days, (1)exercise in hypoxia (Hypoxia; FiO2:14.5%), (2) exercise in normoxia (Normoxia; FiO2:20.9%), and (3)rest (Rest; without exercise). The exercise consisted of 30min pedaling exercise (the load was set as 3% of body weight) followed by repeated sprint exercise [(6s maximal pedaling with 30s rest periods between sprints×6session×2set), the load was set as 7.5% body weight]. During exercise session (16:30~17:30) HR, SpO2, and RPE were evaluated. During subsequent sleep (24:00~7:00) sleep architecture (EEG), skin temperature, and autonomic nerve activity(HF, LF/HF) were further evaluated.

RESULTS: During exercise, SpO2 was significantly lower in Hypoxia (85±0.3%) than in Normoxia (97±0.1%) and Rest (98±0.1%, P<0.05). HR was significantly higher in Hypoxia (144±1 bpm) and Normoxia (138±2 bpm) than in Rest (66±0.4 bpm, P<0.05), with no significant differences between Hypoxia and Normoxia. During 7 hours of sleep, autonomic nerve activity (HF, LF/HF) did not differ significantly among three conditions. Moreover, total sleep time, sleep efficiency, and sleep latency did not differ significantly among three conditions. However, sleep latency of slow wave sleep (SWS; stage 3) was significantly longer in Hypoxia (18.2±11.7 min) than in Normoxia (9.0±0.8 min) and Rest (7.2±1 min, P<0.05).

CONCLUSION: Although strenuous exercise session under hypoxia did not affect sleep efficiency, it significantly delayed the onset of the SWS, which may be potentially negative for sleep quality.

ALL SEX DIFFERENCES IN FORCE-VELOCITY RELATIONSHIP AND RATE OF FORCE DEVELOPMENT DISAPPEAR AFTER NORMALISING FOR MAXIMAL FORCE

SALVAGGIO, F., BRUSTIO, P., PINTORE, A., GROSSIO L., CALCAGNO, E., RAINOLDI, A., SAMOZINO, L., BOCCIA G.
UNIVERSITY OF TURIN

INTRODUCTION: Force-velocity (FV) relationship is characterised by dynamic force production capacities at high (V0) and low (F0) velocities, and then maximal power (Pmax). The rate of force development (RFD) represents a key measure determining the capacity to produce force quickly in isometric conditions starting from a relaxed state. When the FV relationship is obtained from average force and velocity over the movement, RFD could be an underlying factor of force production capacities at high velocity (V0, Boccia et al. 2024). This study aims to analyse comprehensively the variations in FV relationship and RFD parameters between sexes, notably to test the likely association between differences in both RFD and V0.

METHODS: Single-leg knee extensors were tested under isometric and dynamic conditions in 53 healthy subjects (38% female). The protocol included two 5s maximal isometric voluntary contractions (MVC), 15 isometric burst-like contractions (at least 70% of MVC) and dynamic incremental-load knee extensions from the minimum load (i.e., 2.5 kg) up to the individual maximal load. Force and velocity were measured to calculate individual FV relationships using a hyperbolic model. Electromyographic signals were recorded using two 64-electrodes matrices placed on the vastus lateralis and the rectus femoris muscles. The root mean square (RMS) calculated during isometric and dynamic contractions was normalised to the RMS during the MVC.

RESULTS: FV relationships were well fitted by hyperbolic regression (r^2 from 0.983 to 0.993). Independent samples t-test revealed significant sex differences (p<.001) in favour of males in isometric testing for RFD measured at 50 ms (effect size [ES]= 1.2), 100 ms (ES=2.1) and 150 ms (ES=2.4), peak RFD (ES=2.0), MVC (ES=2.1). However, after normalising all the parameters for MVC, the sex differences disappeared. Regarding FV parameters F0 (ES=0.9), Pmax (ES=1.0), and force at Pmax (ES=1.9) were greater in males (p<.001), while V0 was similar between sexes. Again, when normalising the force parameters (i.e. F0 and force at Pmax) for MVC, the sex differences disappeared. Similarly, the normalised EMG signals of both muscles showed no sex differences.

CONCLUSION: Moderate to large sex differences were observed in favour of males in several parameters, including the RFD at 50ms, 100ms and 150ms, MVC, peak RFD, F0, maximal power and force at maximal power. However, after the normalisation of all the parameters mentioned above to MVC, those differences were no longer observed, suggesting that the maximal strength may explain most of the sex differences in rapid isometric and dynamic force production, without any differences in V0 between sexes.

AGE-RELATED DIFFERENCES IN MOTOR UNIT DISCHARGE RATE AS A FUNCTION OF CONTRACTION INTENSITY

CONNELLY, C.D., VALENCIC, T., THOMASON, H., PIASECKI, M., PEARCEY, G., FOLLAND, J., ŠKARABOT, J.
LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Older adults undergo alterations in the neuromuscular system ultimately leading to reduced muscle force generating capacity. The force exerted by a muscle is controlled by motor unit (MU) recruitment and discharge rate, with

the latter having been shown to decrease with advancing age. However, less is known about MU discharge rate modulation with increased contraction intensity in aged compared to younger individuals with alterations in motoneuron structural integrity, ionotropic synaptic input, and neuromodulation indicating potentially greater age-related effects at higher contraction intensities. Therefore, we aimed to examine tibialis anterior (TA) MU discharge rate modulation across a wide range of contraction intensities in older compared to young adults.

METHODS: Fourteen young (6 female; 24±5 years) and 14 older adults (6 female; 71±4 years) matched for physical activity levels (3938 [2723, 6661] vs. 3431 [2068, 4795] MET.min/week, p=0.57) performed isometric dorsiflexion contractions both of a trapezoidal (10 s hold phase) and triangular shape (10 s ascending/descending phase) at 30%, 50% and 70% of maximum voluntary force (MVF). Multichannel electromyography signals were recorded from TA with a 64-channel array and were decomposed using Convolution Kernel Compensation algorithm into MU spike trains. From MU spike trains identified during trapezoidal contractions mean discharge rate during the hold phase was calculated. The MU spike trains during triangular contractions were smoothed with support vector regression, followed by the calculation of the onset-offset hysteresis of pairs of MUs (ΔF) to estimate the magnitude of persistent inward currents. Linear mixed effects models were used to determine if MU properties were predicted by age, contraction intensity and their interaction with MU recruitment threshold as a covariate.

RESULTS: Dorsiflexion MVF was not significantly different between young and older adults (322 [278, 366] vs. 262 [222, 302] N; p=0.06). There was a significant interaction between age and contraction intensity for MU discharge rate (p=0.006). However, post hoc testing did not indicate any differences at individual contractions intensities (30% MVF: 14.5 [13.0, 16.0] vs. 12.7 [11.2, 14.1] pps, p=0.49; 50% MVF: 19.4 [17.9, 20.9] vs. 18.0 [16.5, 19.4] pps, p=0.71; 70% MVF: 26.0 [24.5, 27.5] vs. 25.3 [23.9, 26.8] pps; p=0.99). A significant age by contraction intensity interaction was also noted for ΔF (p<0.001), with greater ΔF noted for young compared to older adults at 70% (6.3 [5.7, 7.0] vs. 4.5 [3.8, 5.2] pps, p=0.006), but not 50% (5.8 [5.1, 6.4] vs. 4.4 [3.7, 5.1] pps, p=0.077) or 30% MVF (4.8 [4.1, 5.5] vs. 4.1 [3.4, 4.8] pps, p=0.6).

CONCLUSION: These findings demonstrate that MU discharge properties are differentially modulated from low to high contraction intensities between young and older individuals in the TA, suggesting alterations in the gain modulation of aged motoneurons.

EFFECTS OF 14 DAYS OF STEPS REDUCTION ON NEUROMUSCULAR FUNCTION AND FATIGABILITY IN YOUNG ADULTS

GATTI, M., COLOSIO, M., PADDEU, S., MARCIANO, A., SAZZI, C., BROCCA, L., PORCELLI, S., PELLEGRINO, M., CANEPARI, M., BOTTINELLI, R.

UNIVERSITÀ DEGLI STUDI DI PAVIA

INTRODUCTION: Physical inactivity (PI) is a critical issue for our society and is linked to increased risk of adverse health outcomes [1]. Disuse models used to simulate physiological consequences of PI, such as bedrest or lower limb suspension, showed muscle wasting and neuromuscular function (NMF) impairments in young adults [2,3]. After steps reduction (SR) interventions, a less invasive model of PI, mild muscle atrophy and controversial impairments in muscle force have been reported [4]. To date, no studies have fully explored NMF and fatigability changes after SR in young adults. This work aimed to assess in-vivo and ex-vivo muscle contractile proprieties and performance fatigability after 14 days of SR in healthy young adults.

METHODS: We recruited 30 (n=16 women) young healthy, normally active, subjects that underwent to 14 days of SR to 1500 steps/day. They were tested before (T1) and after SR (T2). In each time point, participants performed 80 maximal-velocity isotonic concentric knee extension (KE) contractions (1 every 3s) with a load equivalent to 30% of the maximal voluntary isometric contraction (MVIC) torque. Mechanical power output (Pw) of each contraction was calculated. Before (PRE) and immediately after (POST) the fatiguing exercise, KE MVIC was performed. During MVIC interpolated twitch technique was used to investigate voluntary activation (VA). A set of 100Hz doublets (Db100) and single (St) transcutaneous electrical stimulations were also delivered through the femoral nerve on relaxed muscle. Finally, specific isometric force (P0/CSA) and maximal velocity (V0) were determined from skinned single muscle fibers samples from vastus lateralis.

RESULTS: Overall daily steps were reduced by 82%. KE MVIC torque significantly decreased from T1 (149.7□50.0 Nm) to T2 (126.8□47.9 N m; p<.01). SR did not affected VA, St and Db100 torque. Initial Pw was lower T2 (2.97□0.83 W/Kg) compared to T1 (3.27□0.81 W/kg; p<.01). In POST, Pw and MVIC torque loss did not show any intervention effect. P0/CSA didn't change in type 1 fibers, but a significant decrease in type 2 was found (103□50 and 77□36 kN*m2 in T1 and T2, respectively; p<.05). Moreover, V0 increased only for type 1 fibers (from 0.12□0.09 to 0.23□0.14 L/s; p<.05).

CONCLUSION: In healthy young adults, mild reduction in physical activity like SR, caused a significant decrease in force production and mechanical Pw of KE, without affecting fatigability. Classical hallmarks of disuse [5] as reduction in type 2 fibers specific force and increase in type 1 fibers' maximal velocity were found. This suggest that after SR, neuromuscular changes of knee extensors could be, at least in part, related to changes in contractile properties, although no changes were observed by electrical stimulated contractions. Thus, low mechanical load imposed for two weeks is sufficient to cause relevant functional impairments at skeletal muscle level.

ECCENTRIC-ONLY RESISTANCE TRAINING TO CHRONICALLY DECREASE PASSIVE STIFFNESS OF THE HAMSTRING MUSCLE

KAWAMA, R., TAKAHASHI, K., IKIFUNE, H., TOZAWA, H., OBATA, T., ITO, R., HOJO, T., WAKAHARA, T.
DOSHISHA UNIVERSITY

INTRODUCTION: Resistance training is effective in increasing muscular strength and size, but may be empirically believed to increase passive muscle stiffness, potentially increasing the risk of musculoskeletal injuries [1]. Meanwhile, we have recently shown that the passive stiffness of a specific hamstring muscle (semimembranosus [SM]) acutely decreases after a session of eccentric-only stiff-leg deadlift using a combination of long muscle lengths and a long duration (LL [2]). Passive muscle stiffness was reported to chronically decrease after static stretching at moderate to high weekly frequencies (three to six sessions per week [3]). Thus, the present study tested the hypothesis that passive stiffness of the hamstring muscle chronically decreases when eccentric-only resistance training with LL is performed, especially at a relatively high weekly frequency.

METHODS: Thirty-six healthy young males were randomly assigned into two training groups (W2 and W3, n = 12 in each group) and a control group (CON, n = 12). The participants in both training groups performed three sets of 10 repetitions of eccentric-only stiff-leg deadlift at 60–70% of body weight, 50–100% of maximal exercise range of motion with 5 s per repetition for 10 weeks (two and three sessions per week in W2 and W3, respectively). Before and after the intervention period, shear moduli of the biceps femoris long head, semitendinosus, and SM were measured using shear wave elastography. Additionally, maximal voluntary isometric torque of knee flexion and volumes of the biarticular hamstring muscles were measured with a dynamometer and MRI, respectively. For these variables, non-parametric tests were performed.

RESULTS: In W3, the shear modulus of SM (–11.4% [median value]) significantly decreased after the intervention period, but that of the biceps femoris long head (0.6%) or semitendinosus (4.6%) did not change. There were no significant changes in the shear moduli of the biarticular hamstring muscles in W2 or CON. The maximal voluntary isometric torque (20.3% and 26.2%, respectively) and SM volume (5.7% and 7.4%, respectively) significantly increased in W2 and W3.

CONCLUSION: The present study is the first to show that passive muscle stiffness chronically decreases when eccentric-only resistance training with LL is performed, especially at a higher weekly frequency. Moreover, the previous [2] and present studies suggest that an acute decrease in the passive muscle stiffness induced by resistance exercise corresponds to a training-induced chronic decrease in the stiffness. The present findings provide new insights into the current understanding of the training-induced adaptive plasticity of passive muscle stiffness. Our training modality may be a time-efficient strategy for increasing muscular strength and size while minimizing the risk of musculoskeletal injuries.

ADAPTATION OF THE HUMAN RETICULOSPINAL TRACT IN UNTRAINED PARTICIPANTS TO A 6-WEEK ISOMETRIC RESISTANCE TRAINING INTERVENTION.

ATKINSON, E., ANSDELL, P., GOODALL, S., HOWATSON, G., ŠKARABOT, J., THOMAS, K.
NORTHUMBRIA UNIVERSITY

INTRODUCTION: Introduction. Neural adaptations to resistance training in humans have focused on the corticospinal tract (CST), with equivocal results [1]. Non-human primate research has highlighted the reticulospinal tract (RST) as a site of adaptation to resistance training [2], however, longitudinal observations in humans have yet to be performed. This study examined the possible time-course of adaptations within descending motor tracts over a 6-week resistance training intervention.

METHODS: Methods. Twenty-eight participants (age: 31 ± 7 years) were randomly assigned into training and control groups, consisting of fourteen in the control group (age: 31 ± 5 years) and fourteen in the training group (age: 31 ± 8 years). The training group's isometric resistance training intervention was 4 sets of 8 repetitions at 80% maximal voluntary contraction (MVC) of their dominant elbow flexor, occurring twice weekly for 6-weeks and 24–48h apart. Neuromuscular assessments were performed at baseline and end of weeks 1, 2, 3 and 6, with evoked responses recorded at 10% MVC with surface electromyography. Short-interval cortical inhibition (SICI), intra-cortical facilitation (ICF), supra-spinal input (V-wave) assessed cortical function, while motor evoked potentials (MEP) assessed CST excitability. RST excitability was indirectly inferred from responses to cervico-medullary stimulations (CMEPCON) and transcranial magnetic stimulation (TMSCON), paired with a conditioning startling auditory stimuli of ≥ 110 dB, either 80 ms (CMEPCON) or 50 ms (TMSCON) apart[3]. The StartReact protocol [4], also assessed RST function through reaction time responses to visual (VRT), auditory (VART), and startling auditory stimuli (VASRT), quantified through the calculations of RST Gain and auditory – startle response time difference (ARSRΔ).

RESULTS: Results. Training group elbow flexor strength increased compared to controls (14 ± 7% vs 1 ± 5%, $p < 0.001$). For measures of RST function, no interaction effect for CMEPCON responses ($p = 0.54$), TMSCON ($p = 0.56$), or for quantification of StartReact through RST Gain ($p = 0.15$) and ARSRΔ ($p = 0.29$) following the intervention were found. For cortical and CST function, there were also no interaction effects for SICI, ICF, V-Wave or MEP responses ($p \geq 0.09$).

CONCLUSION: Conclusion. While elbow flexor strength increased, indirect measures of RST function did not show evidence of RST adaptation following the isometric resistance training intervention, despite no cortical or CST adaptations. Therefore, this data shows that the RST does not appear to facilitate strength increases following isometric resistance training.

OP-AP03 Training and Testing

DRIBBLE LIKE ROBBEN: WHAT DETERMINES SUCCESSFULNESS IN 1-VS-1 ACTIONS IN ELITE SOCCER?

OONK, G.A., KEMPE, M., BUURKE, T.J.W., LEMMINK, K.A.P.M.

UNIVERSITY OF GRONINGEN

INTRODUCTION: Competitive interactions are an important phenomenon in most team and individual sports. However, research on competitive interactions is mainly conducted in controlled laboratory-based experiments, which raises the question of generalizability towards more dynamic environments in team sports. While studies in rugby and futsal investigated 1-vs-1 actions in training settings, they did not relate their findings to the successfulness of the actions. We seek to close this gap by studying 1-vs-1 actions in competition. Therefore, using a large-scale observation design, this study aims to identify determinants of successful 1-vs-1 actions in male elite soccer.

METHODS: 1-vs-1 actions from 43 Dutch Eredivisie matches were manually selected and labelled on successfulness by three raters. Using tracking data, 24 variables of the 1-vs-1 actions were obtained, divided into three categories: individual (e.g. velocity of the defender), interaction (e.g. relative velocity between the attacker and the defender), and environmental (e.g. the location on the pitch of the action). Multivariate analysis was used to show which (category of) variables discriminated between successful and unsuccessful 1-vs-1 actions.

RESULTS: In total 734 1-vs-1 actions were selected (Fleiss kappa = 0.76) of which 356 were successful and 378 unsuccessful (Fleiss kappa = 0.89). A MANOVA showed a main effect for successfulness (Wilks $\Lambda = 0.881$, $F(23, 710) = 4.178$, $p < 0.001$). Post-hoc analysis with a Bonferroni correction identified five individual variables that differed between successful and unsuccessful 1-vs-1 actions ($p<0.03$): the minimal distance between the attacker and the defender, the minimal distance between the ball and the defender, the variation in the distance between the attacker and the ball, the pressure on the attacker, and the median directional change of the attacker during the action. All five were variables that related to the interaction between the attacker and his environment, while variables for the individual and environment show no significant results.

CONCLUSION: In conclusion, only the variables that were related to the interaction between the attacker and the defenders discriminated between successful and unsuccessful 1-vs-1 actions. These findings can be directly applied to talent identification and scouting in team sports. Although it is often thought that individual speed and acceleration are important for successful 1-vs-1 actions, the results show that the interaction between the attacker and the environment is more decisive for successfulness in 1-vs-1 actions than individual variables. Specifically, the successful 1-vs-1 actions differentiated from unsuccessful ones by showing less pressure exerted on the attacker during the action, a higher degree of ball control by the attacker, and a more direct approach during the action.

MUSCLE TYPOLOGY OF YOUTH TRACK-AND-FIELD ATHLETES PREDICTS THEIR ADULT PERFORMANCE: A PROSPECTIVE STUDY

VANDECAUTER, J., VAN VOSSEL, K., VAN DE CASTEELE, F., DERAVE, W., LIEVENS, E.

GHENT UNIVERSITY

INTRODUCTION: Current talent identification programs struggle to successfully identify track-and-field talents at a younger age, mainly because of poor relation between youth and senior performances [1]. Instead, stable biological and performance-related factors, such as muscle fiber type composition (MFTC), may hold promise for more robust predictions. Fast and slow muscle fibers possess distinct characteristics and their ratio is discipline-dependent in elite track-and-field athletes [2]. With the advent of non-invasive techniques, the assessment of MFTC is no longer restricted to muscle biopsies, enabling its use in talented youth [3]. Therefore, the aim of this longitudinal prospective study is to investigate whether MFTC measured at a younger age, is a good predictor for later track-and-field performance.

METHODS: Between 2010 and 2019, we included 64 talented youth athletes that were allowed into selective track-and field elite sport schools (age = 15.7 ± 1.3 years, range 12 to 18 years). Their MFTC was non-invasively estimated in the gastrocnemius muscle using 3T proton magnetic resonance spectroscopy of the fast-twitch metabolite carnosine. Youth athletes' MFTC was compared to a discipline-specific elite athlete benchmark population (n = 87, ≥ 1050 IAAF points). A categorical approach was used to assign youth athletes as 'match' if their MFTC was within the range (mean ± 1 SD) of the

elite athletes for their discipline, otherwise appointed as 'mismatch'. The personal best IAAF-score was analyzed as performance parameter, with a follow-up period of 3 to 12 years after the muscle scan. Independent sample t-tests were used with significance set at $p \leq 0.05$.

RESULTS: The highest IAAF-score was obtained 3.4 ± 2.4 years after the scan. Two-thirds of the athletes were already training for a discipline matching their MFTC, indicating the importance of the coaches' eye. Nevertheless, one-third was still misclassified. The 'match' athletes achieved a significantly higher IAAF-score (987 ± 110 vs 915 ± 93 points, $p = 0.011$) compared to 'mismatch' athletes, indicating a better later performance if MFTC at youth level matches with the MFTC of the elite benchmark for their discipline. Of all the matching athletes, 36% achieved an all-time best score above 1050 points, i.e. reaching international standards, compared to only 9% with a mismatching MFTC ($p = 0.022$).

CONCLUSION: This study shows for the first time that youth track-and-field athletes who train for a discipline that is deemed optimal based on their MFTC, perform better at adult age. Therefore, the non-invasive measurement of MFTC can be seen as a new and valuable element in talent identification, identifying the ideal discipline for youth athletes around the age of 15 to 16 years. This is likely expandable to other sports, like cycling, where discipline specialization depends on MFTC.

DURABILITY OF SPEED-TIME AND POWER-TIME RELATIONSHIP PARAMETERS DURING OVER-GROUND RUNNING IN A TEAM SPORTS SIMULATION

VASSALLO, C., GRIGGS, A., GRAY, A., KILDUFF, L.P., JENKINS, D., WALDRON, M.

SWANSEA UNIVERSITY

INTRODUCTION: Parameters of the speed- or power-time relationship, such as critical speed (CS) and D-prime (D') or critical power (CP) and W-prime (W') enable non-invasive evaluation of physiological capacities, which can be used to model the 'balance' of W (W'BAL) during intermittent exercise [1]. However, their deterioration during prolonged exercise, described as 'durability' [2], may lead to inaccuracies in W'BAL modelling. This study evaluated i) changes in speed- or power-time parameters during team sport simulations and ii) the relationships between work done in the severe-intensity domain (SID) and the magnitude of change in parameters.

METHODS: Twenty participants consented to take part in four testing visits. Familiarisation and baseline assessments of overground running 3-min tests (3MT) were conducted, with a global positioning system used to measure the speed-time relationship and mechanical work determined via energetic modelling, from which CP (W) and W' (kJ) were calculated. Subsequent visits comprised a 40-min (one-half) or 80-min (full-match) rugby league movement simulation protocol, each followed by the 3MT (40-3MT and 80-3MT). The SID distance (m) >CS and work (kJ) >CP were calculated from each simulation. A repeated measures ANOVA analysed changes in parameters across baseline, 40-3MT and 80-3MT, with post-hoc comparisons where appropriate. Linear regression was used to explain the variance in power-time parameter changes based on SID work. The relationships between baseline parameters and durability were analysed with Pearson's coefficients. Means±SD are presented.

RESULTS: There were no differences (P>0.05) in CS or CP across simulation stages; however, D' and W' deteriorated at each simulation stage and were lowest after the 80-3MT (94±37 m, 19±8 kJ, respectively) compared to baseline (142±50 m, 28±12 kJ, respectively; P<0.001). The SID work explained 41.0% (P=0.01) variance in the W' reductions between baseline 3MT and 80-3MT. There was no relationship between baseline CP or CS and the reduction in W' after 80 min (P=>0.05), but there was an inverse relationship between baseline W' and the reduction in W' after 40 min (r=-0.69; P=0.001) and 80 min (r=-0.76; P=<0.001).

CONCLUSION: These results demonstrate the magnitude and time-course of D' and W' reductions after half- and full-match simulations, whilst highlighting the maintenance of CS and CP. The W-prime reductions tended to be highest among those with higher baseline W' values but were unrelated to CP or CS. The maintenance of CS and CP parameters across protocols was unanticipated, which adds complexity to the understanding of the interdependency between CP and W' or CS and D' parameters. These findings have implications for the accurate modelling of W'BAL during prolonged intermittent running and offer preliminary data to support the future adjustment of models to account for progressive exercise-induced reductions in baseline speed- or power-time parameters.

PREDICTIVE ACCURACY OF RAPID WEIGHT LOSS, SEX DIFFERENCES, AND TEST-RETEST RELIABILITY OF HYDRATION BIOMARKERS FOLLOWING ACUTE PASSIVE DEHYDRATION

DOHERTY, C., FORTINGTON, L., BARLEY, O.

EDITH COWAN UNIVERSITY

INTRODUCTION: Combat sports athletes undergo pre-competition body mass (BM) assessments to check compliance with their chosen weight class. In pursuit of a competitive edge, athletes often resort to rapid weight loss (RWL) practices before weigh-ins, despite associated health risks, and rare fatalities. Some organisations have introduced hydration testing, such

as urine-specific gravity (USG) tests, to mitigate these risks, but the accuracy and reliability of hydration biomarkers in this context remain unclear. Therefore, this study aimed to investigate the predictive accuracy of RWL for explaining biomarker changes, and assess sex differences, while also examining biomarker reliability across two passive dehydration trials.

METHODS: Fifteen male (age: 26.3 ± 3.5 years, BM: 76 ± 7 kg) and fifteen female (age: 28.8 ± 6.4 years, BM: 63 ± 7 kg) combat sports athletes aimed to lose 4% of their BM via infrared sauna (46°C [±0.8]°C and 35% [±3%] relative humidity), on two separate occasions (10.9 ± 5.6 days apart). Biomarkers were collected pre- and post-dehydration and included serum, tear, and urine osmolality (Sosm, Tosm, Uosm), haematocrit (Hct), and USG. Linear regression assessed the predictive accuracy of RWL, and sex differences in biomarker change scores (Δ), the intra-class correlation coefficient (ICC 2,1) measured reliability, and the accuracy of post-USG (≥1.020) was evaluated based on post-Sosm (≥295/301 mOsm/kg) cut-offs.

RESULTS: Male RWL was significantly greater than that of females across both trials (3.44% ± 0.60% vs. 2.53% ± 0.43%, $p < .001$). RWL poorly predicted all biomarker change scores, with the best explanatory power for HctΔ ($R2 = 0.22$, $\beta = 1$, $p = 0.009$). When controlling for RWL, sex (ref male) had a significant effect in explaining HctΔ ($R2 = 0.39$, $\beta = 0.8$, $p = .032$) and SosmΔ ($R2 = 0.25$, $\beta = -3.3$, $p = .005$), but not for urinary or tear measures. Reliability ranged from poor to good; TosmΔ performed worst (ICC = 0.06, $p = 0.37$), while HctΔ showed the best reliability (ICC = 0.61, $p < 0.001$). Post-USG based on a post-Sosm cutoff of 295 mOsm/kg, had an 80% true negative rate (TNR) and a 62% true positive rate (TPR), with 35% false negatives and 2% false positives. Adjusting the Sosm cutoff to 301 mOsm/kg, the TNR decreased to 52%, while the TPR increased to 83%, with 5% false negatives and 33% false positives.

CONCLUSION: All biomarkers displayed considerable variation over both sessions. While RWL displayed the strongest predictive accuracy for blood measures, it only accounted for <25% of biomarker variation. A sex difference in blood biomarker change was observed, with females having a 0.8% lower HctΔ and a 3.3 mOsm/kg greater SosmΔ when controlling for RWL. Overall, the biomarkers were unreliable, and post-USG misclassified almost 4 out of every 10 dehydrated athletes. RWL of ~3.0% did not accurately explain changes in hydration biomarkers, and therefore these measures cannot be recommended for regulatory use in combat sports.

MODELLING THE RELATIONSHIP BETWEEN REPETITIONS LEFT IN RESERVE AND MOVEMENT VELOCITY: A VALID METHOD FOR RESISTANCE TRAINING MONITORING AND PRESCRIPTION, AND FATIGUE MANAGEMENT

JUKIC, I., PRNJAK, K., HELMS, E., MCGUIGAN, M.R.

AUCKLAND UNIVERSITY OF TECHNOLOGY; ABERTAY UNIVERSITY

INTRODUCTION: In resistance training (RT), establishing a relationship between repetitions left in reserve and the mean absolute velocity (RIR-velocity relationship) could allow for objective monitoring, prescription, and real-time adjustment of the training load and set volume. Therefore, we examined the goodness of fit and predictive validity of general and individual RIR-velocity relationships in the free-weight back squat exercise. Moreover, we investigated whether sex, training status and history, personality traits, and different modelling strategies also affect the goodness of fit and the validity of these relationships.

METHODS: Fifty-one resistance-trained people (15 females and 36 males; 18 to 40 years of age) with a wide range of strength levels, training experience, and different training histories were recruited and they performed a one-repetition maximum (1RM) test, and two repetitions to failure (RTF) tests 72 hours apart. RTF sessions were performed with 70, 80, and 90% of 1RM with 10 minutes of rest between sets. The training history and RT practices were examined via questionnaires while the 50-item International Personality Item Pool Big Five Personality Inventory was used to assess stable personality traits via Qualtrics software. Linear and generalised linear mixed-effects models were used to examine 1) factors influencing the goodness of fit of individual RIR-velocity relationships; and 2) the predictive validity of both general and individual RIR-velocity relationships and the factors affecting the validity of these models.

RESULTS: We found a greater goodness of fit of individual RIR-velocity relationships ($R2 = 0.91$-0.97; residual standard error [RSE] = 0.35-1.38) compared to general RIR-velocity relationships ($R2 = 0.45$-0.57; RSE = 1.14-3.47). Individual, but not general RIR-velocity relationships established in the first testing session yielded acceptable predictive validity of RIR (mean error < 2 repetitions) in the subsequent testing session, regardless of the load used. Sex, training status and history, and personality traits did not significantly affect the goodness of fit of general and individual RIR-velocity relationships or their prediction validity (all $p < 0.05$), suggesting the potential generalisability of those findings among resistance-trained populations. Similar results were obtained when both general and individual RIR-velocity relationships were averaged across the loads; this suggests that an individual RIR-velocity relationship covering a range of loads can be used to monitor and prescribe RT with acceptable accuracy.

CONCLUSION: Establishing RIR-velocity relationships enables precise load prescriptions based on daily readiness and provides real-time and accurate insight into individuals proximity to failure during RT. This enhanced understanding could empower sport scientists and coaches to exert greater control over the physiological stimuli applied during RT, potentially fostering more targeted and effective training adaptations.

OP-PN14 Nutrition VI

NUTRITION CULTURE IN ENGLISH PREMIER LEAGUE FOOTBALL: A BOURDIEUSIAN ANALYSIS

FOO, W.L., TESTER, E., CLOSE, G.L., CRONIN, C.J., MORTON, J.P.
LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: In 2020, the Union of European Football Associations (UEFA) published evidence based nutritional guidelines for elite football (1), reflecting the growing recognition of the role of nutrition in supporting football performance. In practice, however, players do not readily meet these guidelines (2). While behaviour change models have explored enablers and barriers to nutritional adherence (3), the cultural factors influencing players' nutritional habits also warrant investigation. Through the lens of Bourdieu Theory (4), this study aimed to explore players' perceptions of the nutrition culture within the professional football environment.

METHODS: An interpretivist paradigm, which emphasizes that reality is subjective and socially constructed, underpins this study. Accordingly, face-to-face semi structured interviews were conducted with purposively sampled male footballers from the English Premier League (EPL) (5 British, 5 Migrant; mean age: 26 ± 6; mean EPL appearances: 106 ± 129). Questions were open-ended to maximise contribution. Data were abductively analysed using thematic analysis (5). Bourdieu theory which includes habitus (acquired disposition and behaviour), capitals (economic, e.g. resources; social, e.g. status), field (arena of social practice) and doxa (taken-for-granted beliefs) informed interviews and analysis

RESULTS: This study revealed five key themes: (1) Habitus, shaped by familial, ethnic and religious backgrounds, influences footballers' dietary habits; (2) Via social capital, managers, teammates and online influences, significantly impact footballers' dietary practices; (3) The rise of football clubs' and players' economic capitals spurred advancements in nutrition provision; (4) An unequal distribution of economic capitals has led to hierarchical practice in the performance nutrition field with personalized nutrition being somewhat enacted at the higher levels, and (5) Body composition measurement is a 'doxic' practice in professional football that warrants challenge.

CONCLUSION: Data showed that the habitual nutritional practices of professional players is influenced by cultural factors associated with their personal upbringing and the context of the specific club in question (e.g. economic resources and/or social capital exerted by managers). Additionally, the field of performance nutrition within professional football is influenced by stakeholder doxic beliefs surrounding the perceived optimal body composition of players, where managers also exert social capital. Practically, these data clearly demonstrate the necessity for player and stakeholder education programmes that seek to equip individuals with both knowledge and practical skillsets to ensure the successful translation of science to practice.

POSTPRANDIAL GLUCOSE AND APPETITE RESPONSES TO DIFFERENT FOOD INTAKE SEQUENCES IN RECREATIONALLY ACTIVE ADULTS

GIRO, R.1,2, TEIXEIRA, V.H.1, REBELO, P.2, BORGES, N.1, BRITO, J.2
1 FACULTY OF NUTRITION AND FOOD SCIENCES, UNIVERSITY OF PORTO 2 PORTUGAL FOOTBALL SCHOOL, PORTUGUESE FOOTBALL FEDERATION

INTRODUCTION: Food intake sequence can impact postprandial glucose (PPG) concentrations in patients with diabetes and healthy individuals. Lower PPG rises and dips are associated with decreased subsequent hunger and energy intake. However, no studies to date have targeted athletes or recreationally active individuals, despite their high carbohydrate (CHO) requirements and the role of CHO on metabolic health and exercise performance. Therefore, this study aimed to evaluate the acute effects of food intake sequence on PPG and appetite perceptions in recreationally active adults.

METHODS: In a randomized crossover counterbalanced design, 10 healthy recreationally active individuals (5 men, 5 women; 22–41 yrs; 21.8±2.5 kg/m2; 4.7±3.1 h/week of exercise) consumed an identical, isocaloric meal in either of two intake sequences: CHO-first or CHO-last. Orange juice, white bread with jam and banana were consumed before or after a high-protein yoghurt and almonds over 15 min. The test-meal was high in CHO (1.59±0.11 g/kg), moderate in protein (0.44±0.03 g/kg), low in fat (0.16±0.01 g/kg) and low in fibre (5.9–6.8 g). Finger-prick capillary blood glucose and appetite ratings on 100-mm visual analogue scales were measured at baseline, 15, 30, 45, 60, 90, 120 and 180 min after the start of the meal. Friedman test with Bonferroni post-hoc was performed to explore differences between food intake sequences over time. Paired t and Wilcoxon signed-rank tests were used to compare time series summary statistics [total area under the curve (tAUC), incremental AUC (iAUC), peak and time to peak]. Spearman rho assessed partial correlations controlling for condition, time, sex, and order effects.

RESULTS: Participants were normal glucose tolerant [4.8±0.5 mmol/L of fasting blood glucose (<5.6 mmol/L) and 6.1±0.8 mmol/L of 2-h PPG during a 75-g oral glucose tolerance test (<7.8 mmol/L)]. Baseline and PPG concentrations were not different between food intake sequences (pairwise comparisons, peak, time to peak, tAUC, iAUC x 120 and 180 min, p>0.05). Desire to eat something salty was greater after consumption of the CHO-first vs. the CHO-last meal pattern (iAUC: 1428 [263–3403] vs. 3876 [780–6881] mm x 120 min, p<0.05). Blood glucose was moderately positively correlated (p<0.001) with satiety (rs=0.577), fullness (rs=0.583), desire to eat something salty (rs=0.457) and savoury (rs=0.522); moderately negatively correlated (p<0.001) with hunger (rs=-0.561) and prospective food consumption (rs=-0.615); poorly positively correlated with desire to eat something sweet (rs=0.385; p<0.001), and very poorly positively correlated with desire to eat something fatty (rs=0.169; p<0.05).

CONCLUSION: Blood glucose was associated with appetite perceptions in healthy, recreationally active individuals. Food intake sequence influenced the desire for specific food types in the hours after a meal. Further research is warranted on the effects of eating order on the health and performance of recreationally active and athletic populations.

DIETARY INTERVENTION FOR A HEALTHY GUT MICROBIOTA DID NOT ALTER PERFORMANCE IN EQUINE ATHLETES

VASSEUR, M., GRIMM, P.2, JULLIAND, S.2, LANGEVIN, N.3, LEPERS, R.1

1.INSERM U1093 CAPS, 2.LABTOFIELD, 3.ECURIE HUNTER VALLEY

INTRODUCTION: Intake of high-starch diets is a strategy for equine athletes to support energetic demand and accelerate muscle glycogen repletion after exercise. However, this strategy induces a shift in gut microbiota composition and acidosis, reducing fiber (cellulose, hemicellulose) digestion, short-chain fatty acids (SCFA) production and absorption. The predominant SCFA, acetate, is an energy substrate for muscles lowering glucose mobilization and inducing less acid production than glucose. We recently demonstrated on equine athletes that fibrolytic efficiency of gut microbiota was associated with improved aerobic capacities. The aim of the present study was to test the hypothesis that replacing a high-starch diet (HS) with a high-fiber diet (HF) would benefit fibrolytic activity of equine gut microbiota and subsequently exercise performance.

METHODS: French Trotters regularly trained (n=21, 2.0±0.1yrs, 447±33kg) fed HS diet (starch: 1495g/day, neutral detergent fibers (NDF): 5151g/day) were included in a longitudinal test. An in vitro fermentation test was performed from fresh fecal samples during 48h to assess the fibrolytic capacity of the fecal microbiota (fibers disappearance and gas production). SCFA concentration and pH were measured in the feces. Maximal oxygen uptake (VO2peak) was determined with an incremental discontinuous test until maximal aerobic speed. Blood samples were taken at rest, immediately after the test, and after 20 minutes of recovery to measure acetate, glucose, lactate, and non-esterified fatty acids concentrations. After basal measurements, 10 horses were fed an isocaloric and isoprotein HF diet (starch: 732g/day, NDF: 5789g/day) for 4 weeks, and the 11 others remained on the HS diet. Measurements were repeated after the 4 weeks. ANCOVA analysis, with basal values as covariate and Tukey post-hoc adjustment was performed to evaluate the impact of diet on each parameter.

RESULTS: Higher fecal pH was observed in HF (p<0.001), probably due to differences in SCFA concentration (HS: 87.7 mmol/L, HF: 65.8 mmol/L, p=0.005). In parallel, acetate proportion was higher in HF (p=0.01), while propionate proportion was lower (p<0.001). In vitro parameters did not vary between groups nor did blood metabolites (p>0.2). VO2peak (HS: 114 ml/min/kg, HF: 109 ml/min/kg, p=0.5) and maximal speed (HS: 12.2 m/s, HF: 12.5 m/s, p=0.2) did not differ between groups.

CONCLUSION: These results confirm that replacing HS diet with a HF diet reduces gut acidosis. SCFA absorption was probably greater in HF diet, as a lower fecal concentration was observed, although this was not confirmed by blood parameters. The alteration in fecal SCFA proportions suggests a shift toward an improvement in fibrolytic activity, even if fibrolytic efficiency measured in vitro was not modified by the diet as it was assumed. This could explain why respiratory parameters and aerobic performance were not significantly affected by the diet. A greater contrast between diets seems necessary to alter performance.

INVESTIGATING THE IMPACT OF EXERCISE ON RIGHT VENTRICLE FUNCTIONAL RESERVE IN ELITE ADOLESCENT FOOTBALLERS USING STRESS ECHOCARDIOGRAPHY

BERRYMAN, B., DOROBANTU, D.M., FRIEDBERG, M.K., PIELES, G.E., WILLIAMS, C.A.

UNIVERSITY OF EXETER

INTRODUCTION: The athletes right ventricle (RV) undergoes remodelling secondary to training, characterised by enlarged end-diastolic volume and augmented myocardial reserve, allowing for increased cardiac output during exercise. Global RV function is determined mainly by transverse and longitudinal function, with transverse proposed to have a greater contribution to global function[1], and this could be of importance during physical activity. This study investigated the rela-

tionship between RV function components and exercise intensity in adolescent athletes. It was hypothesised that RV transverse function would increase more than longitudinal function during exercise.

METHODS: A total of 30 elite male adolescent footballers (mean age 14.9 ± 1.0 y) underwent combined cardiopulmonary exercise test (CPET) and stress echocardiography. Fractional area change (FAC – global function), tricuspid annular plane systolic excursion (TAPSE – longitudinal function) and fractional septal free-wall distance (F-SFD – transverse function) [1] were measured at rest, 0 W, then 50 W increments during exercise. Exercise steps were classified by intensity domain based on the gas exchange threshold (GET) in low (50 W), moderate (below the GET) and high (above the GET). Changes in CPET parameters, RV function and RV cardiac reserve (relative difference in RV function to rest) were analysed using linear mixed models.

RESULTS: All mean RV function parameters increased from rest to high intensity (FAC: 41 vs. 62.3%, TAPSE: 25 vs 33.5 mm, F-SFD: 20.8 vs 41.4%, p<0.001 for all). Transverse function reserve at high intensity exercise was significantly higher than longitudinal function reserve (mean F-SFD reserve: 126.9%, 95% CI [89.8-164.1] vs TAPSE reserve: 38.4%, 95% CI [27.6-49.3], p<0.05). Mean FAC reserve at high intensity was 54.1%, 95% CI [45.2-63.1]. The absolute difference between TAPSE and F-SFD reserve increased from low to high intensity exercise (p<0.05), while the TAPSE to F-SFD ratio decreased (p<0.05). FAC, TAPSE and F-SFD all demonstrated linear relationships with HR, VO2 and O2 pulse (p<0.05), FAC demonstrated the strongest relationship with each parameter.

CONCLUSION: As hypothesised, transverse function increased more than longitudinal function during exercise, but FAC correlated best with oxygen uptake. These findings reflect the complex, three-dimensional nature of RV function augmentation in response to exercise. Therefore, assessing only TAPSE and FAC, as commonly conducted in practice, does not fully characterise the global RV exercise response in athletes. A multi-parametric approach should be used, including transverse function reserve.

NOVEL IMPLICATION OF GENOMIC LOCI WITHIN ITGB2, COL5A1 AND VEGFA COLLECTIVELY ASSOCIATING WITH ANTERIOR LIGAMENT RUPTURE SUSCEPTIBILITY IN LARGE COHORT FROM SOUTH AFRICA, POLAND, SWEDEN AND AUSTRALIA

SEPTEMBER, A., DLAMINI, S.B., SAUNDERS, C.J., CIESZCZYK, P., FICEK, K., HÄGER, C.K., STATTIN, E., NILSSON, K.G., EYNON, N., FELLER, J., TIROSH, O., BOPE, C.D., CHIMUSA, E.R., COLLINS, M.

UNIVERSITY OF CAPE TOWN

INTRODUCTION: Independently, genetic loci within genes ITGB2 (beta 2 subunit of integrin), COL5A1 (alpha 1 chain of type V collagen) and VEGFA1 (vascular endothelial growth factor A) have been associated with rupture susceptibility of the anterior cruciate ligament (ACL-R). These genes have diverse functions including cell-cell communication, maintaining structural integrity and regulating new blood vessel formation which are all integral to ligament tissue integrity. The aim of the study was to identify key genetic loci which collectively maybe relevant to maintaining extracellular matrix tissue integrity of the ligament.

METHODS: A genetic association was conducted for a combined cohort recruited from Australia, Poland, Sweden, and South Africa. Participants analysed in this study included uninjured controls CON=584; participants with ACL ruptures ACL-R=731 and a sub-group with non-contact mechanism of ACL ruptures NON=425. Participants were genotyped for ITGB2 (rs2230528 C/T); COL5A1 (rs12722 C/T) and VEGFA (rs699947 C/A, rs2010963 G/C) polymorphisms. Statistical analyses were conducted using the programming environment R. Inferred allele combinations were constructed as a proxy for potential gene-gene interactions using genotype data. Statistical significance was accepted when $p < 0.05$, and the false discovery rate (FDR) procedure was used to adjust for multiple comparisons.

RESULTS: Significant distributions were noted for combinations between ITGB2 (rs2230528 C/T); COL5A1 (rs12722 C/T) and VEGFA (rs699947 C/A, rs2010963 G/C). The C-C-A-G combination was overrepresented in the CON (19%) compared to the ACL-R (ACL-14: 5%, p=1.x10-4; OR:0.93; 95% CI: 0.61-1.41) group and ACL-NON (ACL-NON: 14%, p=0.002; OR:0.96; 95% CI: 0.61-1.51) subgroup. The C-T-C-C combination was overrepresented in the CON (13%) compared to the ACL-R (ACL-R:10 %, p=0.023; OR:0.76; 95% CI: 0.46-1.26) group and ACL-NON (ACL-NON: 10%, p=0.003; OR:1.11; 95% CI: 0.63-1.79) subgroup. Similar findings were found when males and females were analysed separately.

CONCLUSION: The novel associations highlight key genetic loci which in combination are associated with ACL ruptures susceptibility in a large cohort. In addition, the diversity of the gene functions in this risk model highlight the collective contribution towards maintaining tissue integrity.

THE VEGFA AND KDR GENES ARE ASSOCIATED WITH BILATERAL OR MULTIPLE CHRONIC ACHILLES TENDON INJURIES

COLLINS, M., BRAZIER, C.D., MKUMBUZI, N.S., SEPTEMBER, A.V., LANGUETTE, M.J.N.

UNIVERSITY OF CAPE TOWN

INTRODUCTION: Chronic Achilles tendinopathy (AT) is prevalent in athletes, specifically in sports with a large running component. It presents as swelling, impaired lower limb function and pain. Although the mechanisms are unclear, current theories implicate structural changes and neovascularisation in AT. Vascular endothelial growth factor (VEGF) and its receptor referred to as kinase domain receptor (KDR) are key regulators of neovascularisation and can be associated with

pain. Polymorphisms within the VEGFA and KDR genes have previously been associated with musculoskeletal soft tissue injuries. The primary aim of this study was to identify whether VEGF and KDR polymorphisms were associated with (i) the severity of AT, (ii) AT ultrasound findings and (iii) self-reported measurements of Achilles tendon pain using multidimensional pain scales.

METHODS: 185 recreational athletes with clinically confirmed AT were recruited from Cape Town, South Africa. The injured and uninjured Achilles tendons were examined using conventional grayscale ultrasound. Tendinopathy pain was rated by completing the VISA-A, Short-form McGill Pain Questionnaire (sf- MPQ), and Short-form Brief Pain Inventory (sf-BPI) questionnaires. 194 asymptomatic healthy appropriately matched individuals with no history of tendon injuries were also recruited for this study. Participants were genotyped for VEGFA (rs699947, C/A; rs2010963, G/A) and KDR (rs2071559, G/C; rs1870377, T/A).

RESULTS: The VEGFA rs699947 CC genotype was significantly associated with decreased risk of bilateral AT, while the A-G VEGFA inferred haplotype constructed from rs699947 and rs2010963 was associated with increased risk of bilateral AT. The KDR rs2071559 AA genotype was significantly associated with increased risk of a history of multiple (two or more) AT, while the G-T and A-A KDR inferred haplotypes constructed from rs2071559 and rs1870377 were associated with decreased risk and increased risk of multiple and/or bilateral AT, respectively. The C-G and A-A VEGFA rs699947 and KDR rs2071559 allele-allele interactions were significantly associated with decreased and increased risk of bilateral or multiple injuries respectively. There were no significant differences in the diameters or the relative number of abnormal ultrasound findings of the injured and uninjured Achilles tendons between the VEGFA and KDR genotype groups. Finally, there were also no significant differences in VISA-A, sf-MPQ and sf-BPI scores, as well the sub-scale scores between the genotype groups.

CONCLUSION: The novel findings of this study implicate the VEGF and KDR genes, and by implication the potential biological role of the angiogenesis signalling pathway, with bilateral and/or multiple Achilles tendinopathy risk. The investigated variants within these genes however were not associated with tendon diameters, the relative number of abnormal ultrasound findings or self-reported Achilles tendon pain measured using multidimensional pain scales.

RELATIONSHIP BETWEEN LOWER EXTREMITY MUSCLE ARCHITECTURE AND KNEE STRENGTH IN ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTED MALES

EMIRZEOGLU, M., AYAZOGLU, M.A., ONER, K., AYNACI, O.

KARADENIZ TECHNICAL UNIVERSITY

INTRODUCTION: There is a known deficit in the structural and functional properties of knee-related muscles in individuals who undergo anterior cruciate ligament reconstruction. However, there is insufficient evidence regarding the relationships between these properties. The objective of this study was to investigate the correlation between the architectural features of the six lower extremity muscles and the strength of the knee flexor and extensor muscles in patients who had undergone anterior cruciate ligament reconstruction using hamstring autograft.

METHODS: The study included 33 male participants (age: 24.06±4.37 years, height: 175.55±6.43 cm, weight: 77.88±10.81 kg, time after reconstruction: 14.55±6.21 months). Ultrasonography was used to assess the architectural characteristics of the vastus lateralis (VL), rectus femoris (RF), tibialis anterior (TA), biceps femoris longus (BFL), gastrocnemius medialis (GM), and gastrocnemius lateralis (GL). Muscle strength for knee flexion and extension was evaluated using an Isomed 2000 isokinetic dynamometer in concentric mode at 60 and 180°/s. All assessments were conducted on both the injured and uninjured limbs. The data was analyzed using Pearson and Spearman tests in the SPSS program.

RESULTS: On the injured limb, a significant relationship was found between the VL thickness and peak torque extension at 60°/s (r=0.387; p=0.046). Similarly, there were significant relationships between GM thickness and peak torque extension (r=0.430; p=0.016), peak work extension (r=0.486; p=0.006), peak torque flexion/extension (r=-0.418; p=0.019), peak work flexion/extension (r=-0.457; p=0.010), peak work extension/weight (r=0.360, p=0.047) and total work extension (r=0.437, p=0.014). There was no significant relationship between muscle architectural characteristics and muscle strength parameters at 180°/s (p>0.05). According to the analysis of the differences between the limbs, there was a significant relationship between peak work flexion/extension at 60°/s and thickness of the RF and BFL (r=-0.414, p=0.036; r=-0.406, p=0.026, respectively). There was a significant relationship between GM thickness and peak torque flexion/extension at 60 and 180°/s (r=-0.381, p=0.034; r=-0.411, p=0.022, respectively). Similarly, there were significant relationships between TA thickness and peak torque flexion/extension (r=-0.514, p=0.005; r=-0.585, p=0.001, respectively) and peak work flexion/extension (r=-0.484, p=0.009; r=-0.554, p=0.002, respectively) at 60 and 180°/s.

CONCLUSION: The muscle strengths of the knee flexors and extensors in anterior cruciate ligament reconstructed males are related to the architectural characteristics of these muscle groups, as well as the GM and TA. Therefore, postoperative rehabilitation should take a holistic approach to the muscles of the lower extremity.

COMBINED EFFECTS OF PRE-COOLING AND IN-PLAY COOLING BREAKS USING ICE TOWELS AND COLD DRINKS DURING FOOTBALL MATCHES IN WARM CONDITIONS.

SCHWARZ, E., DUFFIELD, R., ALANIS, A., OLIVEIRA, C., DUARTE MUÑOZ, M., ALANIS, M., LARA, A., COSTA, J., FREEZE, A., MEYER, T.

SAARLAND UNIVERSITY

INTRODUCTION: Playing in hot environmental temperatures is a growing concern for sporting and football organisations worldwide. Therefore, to support player health and minimise performance deterioration during football in the heat, strategies, including cooling procedures and breaks in play, have been proposed; however, investigations in field settings remain scarce (Gouttebarge et al., 2023).

METHODS: In total, 22 male academy soccer players (age 17 ± 0.8 y) participated in two matches in warm conditions (25.5 ± 2 °C WBGT) and received a cooling intervention (COOL) or a control condition (CON) in a randomised cross-over design. COOL consisted of cold towels (6-9 °C) and cold drinks (5 °C) for 10min of pre-cooling prior to the warmup, 10min before the kick-off, 10min at halftime and for an additional 3min during cooling breaks at 25min into each half. The CON received a placebo drink (17 °C) and no cooling at the same time frames. Core body temperature (Tcore), heart rate (HR), match running performance via gobal positioning system (GPS), sweat loss and fluid intake, rating-of-fatigue (RoF), rating of perceived exertion (RPE), thermal sensation (TS) and perceptions regarding likeability and performance benefits were measured throughout the match-day.

RESULTS: Players reached a maximum Tcore of 39.2 ± 0.5 °C in COOL, which did not differ from CON (39.1 °C ± 0.5 °C; $p \geq 0.05$). Further, there were no differences between conditions for Tcore, HR, GPS, RoF or RPE ($p \geq 0.05$), but TS was lower in COOL during respective breaks ($p < 0.05$). Players sweated significantly less in COOL than in CON (2.5 ± 0.5 L vs 2.9 ± 0.6 L) but made up for that by increasing fluid intake (COOL: 1.2 ± 0.3 L; CON: 1.4 ± 0.3 L). Further, players rated the cold towels and cold drinks better than the placebo drinks ($p < 0.05$) and perceived more benefits from COOL than CON ($p < 0.05$).

CONCLUSION: No physiological or performance benefits were observed for the cooling intervention other than the reduced sweat rate. Given the observed warm but not hot environmental conditions, heat strain remained moderate for both groups and may have impacted the effectiveness of the cooling strategy. Nevertheless, the 3min cooling breaks seemed to attenuate the continuous rise in Tcore described in matches without breaks (Mohr et al., 2011). Future observations are needed to investigate the potential benefits of this strategy in hotter temperatures.

EXPLORING THE DEPENDENCY OF INFORMATIONAL TRANSFER BETWEEN CORE OR SKIN TEMPERATURES AND SUDOMOTOR ACTIVITY AMONG HEALTHY PARTICIPANTS OF VARYING THERMOREGULATORY CONTROL

WALDRON, M., PEEL, J., PAGE, J., SCOTT, G., HEFFERNAN, S., TALLENT, J., JEFFRIES, O.

SWANSEA UNIVERSITY, UK; NEWCASTLE UNIVERSITY, UK; UNIVERSITY OF ESSEX, UK.

INTRODUCTION: During hyperthermia, integration of afferent input from central and peripheral thermoreceptors initiates efferent sympathetic signals to activate sweat glands in pulsatile bursts. In this feedback system, core temperature (Tcore) is the primary controlled variable, with skin temperature (Tskin) providing 'auxiliary' dynamic feedback [1]. However, the connectivity of efferent signalling between Tcore, Tskin and sweating, as well as the synchrony of sweating between skin sites, across individuals of varying thermoregulatory control has not been investigated. Therefore, we evaluated i) connectivity between Tcore, Tskin and local eccrine sweating of the arm and chest during passive heating and ii) the temporal synchrony of arm and chest sweating.

METHODS: Thirteen participants completed 90 min passive heating, twice, across one-week (38±0°C, relative humidity 56±2%). Local sweat rates were continuously measured on the ventral forearm and chest, alongside Tcore (rectal) and mean Tskin (chest, arm and leg). Changes in Tcore across the protocol and thermosensitivity (Tcore change at sweat onset) were measured to determine thermoregulatory control of the sample. Transfer entropy (TE) was used to quantify information flow between Tcore, Tskin and all sweating sites, with higher values demonstrating greater connectivity. Relationships between thermoregulatory control measures and TE were evaluated using repeated measures correlations. Cross-correlation was used to assess sweating synchrony across the two sites. Paired t-tests assessed differences between TE values. Data are means±SD.

RESULTS: The TE for Tcore-arm (0.007±0.005 bits) and Tcore-chest (0.009±0.010) was lower ($P < 0.01$ and $P < 0.01$) than Tskin-arm (0.019±0.014 bits) and Tskin-chest (0.022±0.015 bits), respectively, denoting higher information flow from the skin to sweating sites. There were no differences between arm and chest Tskin TE values ($P = 0.31$). Both Tskin-arm TE and Tskin-chest TE were inversely related to the Tcore increases ($r = -0.56$ and -0.57, respectively) and thermosensitivity values

(r= -0.37 & -0.46, respectively), while Tcore TE values were unrelated (P>0.05). Cross-correlation analysis revealed no time-lag between chest and arm site peak relationships, which were strongly correlated (r=0.98±0.03).

CONCLUSION: The notion of Tskin as a dynamic auxiliary feedback mechanism [1] is supported, with reliance upon informational flow between Tskin and sweating of the arm and chest to maintain control of Tcore, which has relatively less TE to sweating sites. Individuals with smaller increases in Tcore and faster sweating onset possessed greater connectivity between Tskin and sweating sites. The temporal correspondence confirms the assumed synchrony between sweating sites, indicating that the pattern of this informational flow is likely to be similar across anatomical locations. These findings may inform future passive assessments of thermoeffector feedback loops.

UNALTERED INTESTINAL FATTY ACID BINDING PROTEIN (IFABP), CYTOKINE AND CHEMOKINE RESPONSES TO PROLONGED PASSIVE HYPERTHERMIA IN HEALTHY HUMANS

GIBSON, O., LAITANO, O., WATANABE, K., GONZÁLEZ-ALONSO, J.

BRUNEL UNIVERSITY LONDON

INTRODUCTION: Hyperthermia, whether passive or exertional, can cause small intestine epithelial injury. Epithelial injury can elevate gastrointestinal permeability, facilitate endotoxin translocation and an inflammatory cytokine/chemokine response which are contributory factors in heat illness (Garcia et al., 2022). Exercise-heat stress causes epithelial injury as quantified by changes in intestinal fatty acid binding protein (iFABP) (Walter, et al., 2021a), and a greater inflammatory response relative to normothermic exercise (Garcia et al., 2022). Responses during passive hyperthermia of equivalent magnitudes to exercise-heat stress have yet to be clearly described (Walter et al., 2021b). This experiment aimed to quantify the changes in iFABP, and cytokine/chemokine responses during prolonged passive hyperthermia. It was hypothesised that passive hyperthermia would increase iFABP and cytokine/chemokine concentrations.

METHODS: In a counterbalanced order, eight young, healthy males visited the lab on four occasions to undertake 3 h of rest (CON); 3 h of one leg heating (OLH); 3 h of two legs heating (TLH); and 2.5 h of whole-body heating (WBH). Heating was applied via a water perfused garment circulating 50°C water. Core (Tcore) and thigh muscle temperature (Tm) were measured continuously, with the concentration of iFABP and selected cytokines and chemokines (EGF, Eotaxin, FGF-2, FLT-3L, Fractalkine, G-CSF, GM-CSF, GRO, IFN-α2, IFN-γ, IL-6, IL-10, IL-12p40, MCP-3, MDC, sCD40L, TGF-α, TNFα, VEGFα) quantified periodically. Regional (Leg, arm and head) and systemic haemodynamics (cardiac output) were measured by echocardiography and Doppler ultrasound to quantify torso blood flow.

RESULTS: Tcore and Tm increased from baseline in OLH (+0.4 ± 0.2°C, +3.4 ± 1.2°C), TLH (+0.7 ± 0.2°C, +3.4 ± 1.3°C) and WBH (+2.3 ± 0.4°C, +6.0 ± 1.7°C) respectively ($p < 0.05$), but were unchanged in CON. Torso blood flow increased ($p < 0.05$) from baseline in OLH (+0.26 ± 0.51 L.min-1), TLH (+0.47 ± 0.60 L.min-1) and WBH (+3.24 ± 1.43 L.min-1), but was also unchanged in CON. Cardiac output increased in OLH (+2.1 ± 0.6 L.min-1), TLH (+3.4 ± 0.7 L.min-1), and WBH (+7.3 ± 1.0 L.min-1) vs CON respectively ($p < 0.05$). Circulating iFABP, and all chemokine/cytokines were unchanged from baseline ($p > 0.05$) in CON, OLH, TLH or WBH.

CONCLUSION: These data identify that iFABP and circulating cytokine and chemokine concentrations do not significantly increase during prolonged local and systemic passive heating. This finding questions the independent effect of hyperthermia on circulating markers of gastrointestinal permeability and subsequent inflammation in healthy humans.

HOT WATER IMMERSION PROTOCOL WITH AN OLDER POPULATION: A PILOT STUDY

COLE, E., JACKSON, K., DONNAN, K.J., SIMPSON, A.J., GARRETT, A.T.

UNIVERSITY OF HULL

INTRODUCTION: Hot water immersion (HWI) is being explored as a practicable and accessible method of heat acclimation for the general population. However, there are questions as to the applicability of these protocols in relation to people's tolerance, affective responses and safety. This research aimed to identify practical insights into more accessible heat acclimation methods for an ageing population (45-75 years) by comparing the efficacy a potentially more tolerable Arms Out method (thereby reducing the submerged surface area), against an "Arms In" submersion protocol.

METHODS: Employing a randomised experimental cross-over design, nine healthy highly trained adults (7 males, 2 females; aged 52±6 years) participated. Participants first engaged in a 6-min walk test to establish fitness levels, followed by two 45-min controlled HWI trials ('Arms In' and 'Arms Out') in a hot tub (40°C) located in an environmental chamber (21°C, 45% relative humidity). The 'Arms In' condition required participants to be submerged up to the base of the neck, whereas 'Arms Out' required participants to be submerged up to mid sternum, with their arms exposed on the side of the hot tub. Physiological measurements included heart rate, mean skin temperature, and mean rectal temperature. Perceptual measures included thermal sensation, thermal comfort, affective valence, and the 32-item Brunel Mood Scale. Each

measurement was recorded at baseline then every 5-mins, except the Brunel Mood Scale which was taken at baseline and at 15-min intervals.

RESULTS: All participants completed both trials. The 'Arms In' immersion protocol induced a significant rise in core temperature from 20-mins ($p<0.05$), with all participants experiencing a ≥1°C increase by 35-mins. 'Arms Out' also showed a significant rise in core temperature across the protocol, however it was significantly lower than 'Arms In'. Mean temperature change from baseline to end point for 'Arms In' was 1.64±0.55°C ($p>0.05$) vs 0.54±0.33°C ($p>0.05$) for 'Arms Out'. Participants, however, reported significantly higher discomfort with 'Arms In'. This was shown in increased mean values for thermal comfort ($p<0.05$), affective valence ($p<0.05$) and elevated values for tension on the Brunel Mood Scale ($p<0.05$).

CONCLUSION: These findings highlight the need to consider perceptual tolerance alongside efficacy of HWI protocols to develop practical heat acclimation methods for the general population that will both be utilised (i.e., are less unpleasant) and induce adequate physiological adaptations. The 'Arms In' method utilised shows the potential effectiveness of HWI to induce sufficient physiological strain for heat acclimation method, however the perceptual tolerance of such protocols is important to consider. A protocol that encompasses the subjective discomfort felt against the physiological stress needed to achieve adaptations should be the avenue for further study.

IMPACT OF AIRFLOW ON THERMOREGULATION AND HEAT STORAGE DURING EXERCISE IN EXTREME HOT ENVIRONMENTS

AGER, L., JEFFRIES, O.
NEWCASTLE UNIVERSITY

INTRODUCTION: Convective airflow facilitates human thermoregulation in ambient temperatures (Tamb) typically below skin temperature (Tsk) (~35°C) during exercise and at rest. In higher temperatures, as typified during extreme heat wave scenarios, it is unclear how convective airflow exceeding Tsk may impact the maintenance of body core temperature during exercise. The aim of this study was to examine conductive airflow in extreme temperatures to aid our understanding of thermal, cardiovascular and perceptual strain during exercise.

METHODS: Thirteen trained, non-heat acclimated males [age 30±6 years; body mass 73.3±7.8 kg; height 181.4±5.1 cm; peak oxygen uptake 61.5±5.1 ml kg-1 min-1; peak power output (PPO) 412±36 W] completed four separate 30-min cycling bouts at 50% PPO in four differing environmental conditions: 37°C and 45°C each with (37F, 45F) and without (37NF, 45NF) dual fan-assisted airflow (~3 m.s-1). Cardiovascular measures of rectal core temperature (Tc), mean Tsk, heart rate (HR) and oxygen consumption were recorded continuously. Perceptual measures of Relative Perceived Exertion and Thermal Sensation were recorded every 3-min. Whole Body Sweat Loss (WBSL) was estimated from pre vs post body mass. A two-way repeated measures ANOVA was performed to identify differences between trials. Statistical significance was set at $P<0.05$.

RESULTS: Tc was different between conditions ($P = 0.022$), changed with time ($P<0.001$) and showed an interaction effect ($P<0.001$). During the latter stages of exercise, we observed the change from baseline in 37NF was 15% greater than 37F, and 45NF was 12.5% greater than 47F. WBSL was different between conditions ($P<0.001$), being greater with respect to Tamb in 45NF vs 37NF (+33%, P=0.007) and 45F vs 37F (+35%, $P = 0.008$). However, WBSL did not differ (<6% difference) in similar Tamb irrespective of fan, between 37NF vs 37F ($P = 0.752$) and 45NF vs 45F ($P = 0.752$). Cardiovascular strain indicated by HR differed by condition ($P = 0.001$), temporally ($P<0.001$), and showed an interaction effect ($P<0.001$). Mean HR was greater during 37NF vs 37F (+7 bpm, $P = 0.07$), however this difference was not evident in higher temperatures 45NF vs 45F (+4 bpm, $P = 0.150$). HR was greater during 45NF vs 37NF (+10 bpm, $P<0.001$) and 45F vs 37F (+13 bpm, $P<0.001$).

CONCLUSION: Convective airflow during exercise in 37°C Tamb reduced thermal, cardio and perceptual strain. In more extreme temperatures where Tamb exceed Tsk (Tamb 45°C), airflow did not result in greater heat storage and instead amplified heat loss. Interestingly these differences were not supported by changes in WBSL. Our data suggests that even at higher Tamb, the addition of airflow promotes evaporative potential and sweat efficiency sufficiently to offset the increase in dry heat transfer gain. In conditions of low humidly (30%) our findings provide clear evidence for the use of conductive airflow during exercise to improve thermal tolerance and mitigate heat illness risk in extreme temperatures up to 45°C.

SKELETAL MUSCLE DETERMINANTS OF ROWING PERFORMANCE

BELLINGER, P., ROBERTS, L., MORRIS, K., DERAVE, W., LIEVENS, E., KENNEDY, B., CHARLES, J., WACKWITZ, T., MCGILL, A., DUHIG, S.
GRIFFITH UNIVERSITY

INTRODUCTION: Elite rowers present with diverse physiological profiles (van der Zwaard et al. 2018; Fukuda et al. 2011; Alföldi et al. 2021) which may be due to, in part, variation in the underpinning muscle characteristics, such as muscle

oxidative capacity, architecture, volume, typology and strength. Nonetheless, the extent to which these muscle characteristics explain rowing performance has not been determined in a systematic manner previously. In this study, we aimed to identify the skeletal muscle determinants of rowing performance and pacing in elite rowers.

METHODS: 22 well-trained rowers (13 male) completed a 7-stage incremental rowing ergometer test to determine rowing economy, the lactate threshold, lactate turn point and VO2peak. The final stage of the incremental test was a maximal effort, representing a 4-min time-trial and was recorded as the criterion dependent variable (i.e., 4 min TT). We also expressed the relative distance that was covered in each minute of the 4 min TT to investigate pacing strategy. Rowers also completed a series of strength and power assessments including loaded and unloaded squat jumps, an isometric mid-thigh pull and 1-repetition maximum (RM) pull up and 3-RM leg press. Rowers underwent an assessment of body composition by dual-energy x-ray absorptiometry, magnetic resonance imaging of their thigh to determine volumes of the major hip- and knee-spanning muscle functional groups and diffusion tensor imaging to estimate muscle fascicle lengths, pennation angles and physiological cross-sectional area of the vastus lateralis (VL). Carnosine content was quantified by proton magnetic resonance spectroscopy in the soleus and expressed as a Z-score to estimate muscle typology. Data were analysed using multiple stepwise regression analysis.

RESULTS: The majority of rowers had negative Z-score values (17/22; Z-score = -0.44 ± 0.85), indicative of a greater estimated proportion of type I fibres, with similar variation in both male and female rowers. Male rowers had greater normalized knee extensor muscle volume (19.2 cm3·kg−1) compared to female rowers (16.8 cm3·kg−1), while VL fascicle lengths were similar. When controlling for lean body mass and sex, muscle fascicle length in the VL, VO2peak and isometric mid-thigh pull peak force explained 82% of the variation in final stage of the incremental test (i.e., 4 min TT). Muscle typology was the only muscle characteristic that explained variation in pacing strategy, whereby rowers with a higher Z-scores (i.e., greater estimated proportion of type II fibres) started the 4 min TT more conservatively but covered a greater relative distance during the second half.

CONCLUSION: In the context our study, these findings indicate that rowers should focus on increasing VL fascicle length, isometric mid-thigh pull strength and aerobic power. Muscle typology was associated with preferential pacing strategies and could be used to inform optimal boat crew pairings to maximise pacing and performance.

PHYSIOLOGICAL RESPONSE FOR ELITE ROWERS IN A 4-WEEKS TRAINING CAMP AT ALTITUDE 2100 METERS

CHAN, Y.Y., TAI, C.H., LO, K.K., CHAN, L.H., LO, W.K., HUANG, Z., WU, J.
HONG KONG SPORTS INSTITUTE

INTRODUCTION: Rowing events are typically raced over 2000m, which last for 5.5-7 mins [1]. A number of studies indicated that rowing performances were dependent on energy systems, with 70-80% contributed by aerobic metabolism and 20-30% derived from anaerobic metabolism [2,3]. Therefore, it is common for rowing athletes to who live in sea level to train at moderate altitude, in order to improve their endurance performance [4]. In this study, the physiological response of elite rowing athletes who took part at a 4-weeks altitude training camp at altitude 2100 meters were investigated.

METHODS: Twenty-seven elite rowing athletes from the Hong Kong Rowing Squad participate in this study (18 male,9 female, age 22.4±3.8). All subjects normally live at sea-level and participated a 4-weeks altitude training camp at altitude 2100 meters. Physiological parameters including hemoglobin (Hb) and body weight were monitored throughout the camp. Incremental test with rowing ergometer (Model D, Concept 2, USA) consists of seven stages of 1km were repeated at 7 days pre-camp, the 16th day during the camp, and 3 days post-camp. 30 mins rowing ergometer training at 22 spm were carried out every week to assess the performance of the rowers during the camp. A repeated measures ANOVA was used to detect changes between different time points of the parameters, effect sizes expressed as partial eta-squared ($\eta 2$). Significance was set at $P<0.05$.

RESULTS: Mean Hb was 14.0±0.9, 15.4±1.0, 15.3±0.9, 15.4±0.9, 15.2±1.1 g/dl for pre-camp, and week 1-4 respectively. Significant differences were found between pre-camp and week 1-4 ($P=0.00$, $\eta 2=0.44$). Mean body weight was 70.95±8.46, 70.4±8.5, 70±8.59 and 69.66±8.44 kg for week 1-4 respectively. Significant differences were found between week 1 to 4 ($P=0.00$, $\eta 2=0.21$). Mean power at anaerobic threshold of incremental rowing ergometer test were 250.0±47.6, 246.5±50.7 and 273.2±52.4 W for pre-camp, during-camp and post-camp respectively. Significant differences were found between pre-camp and post-camp ($P=0.00$, $\eta 2=0.50$). Mean power of 30 mins rowing ergometer training at 22 spm were 197.3±39.8, 203.5±42.0, 200.2±41.1 and 203.1±43.4 W for week 1-4 respectively. Significant differences were found between week 1 to 4 ($P=0.01$, $\eta 2=0.18$).

CONCLUSION: Hb increases significantly by 10.1% since the first week of the altitude camp when compared with pre-camp baseline. A trend of body weight decreases for a total of 1.7% throughout the camp. The anaerobic threshold power of incremental test have been increased by 9.3% throughout the camp. The 30 mins rowing ergometer training power were the lowest at week 1 of the camp, then increased by 3.0% from week 1 to week 4. In summary, Hb and anaerobic threshold power increases, with body weight decreased by taking part in the altitude camp, while 30 mins ergometer power increased from week 2 of the camp.

ANAEROBIC POWER AS A DETERMINANT OF PERFORMANCE IN ELITE KAYAKING: THE INTERPLAY BETWEEN AEROBIC CAPACITY AND LACTATE ACCUMULATION

MIKA, T., SEKERA, J., BOLEK, E., NOVAKOVA, M.
CASRI, PRAGUE

INTRODUCTION: Performance in elite kayaking is influenced by a complex interplay between aerobic and anaerobic physiological capacities. This study focused on the specific roles of anaerobic power, demonstrated by peak power (PP) and mean power (MP), in relation to blood lactate concentration and aerobic capacity, measured by VO2max. Kayakers competing at national (Nat) and international (Int) level were assessed.

METHODS: A cross-sectional analysis was conducted on 25 male elite kayakers (23 years ± 4 years) stratified into performance levels. Athletes underwent a spiroergometric test to determine VO2max and a Wingate test to measure anaerobic power (PP and MP). Lactate levels were obtained at the seventh minute post-exercise. Descriptive statistics, normality distribution Shapiro Wilk test and for homogeneity of variance Levenes test, Pearson correlation, T- test for independent variables and regression analyses were used to identify key performance determinants.

RESULTS: A comparative analysis of kayaking performance metrics revealed that international-level kayakers (Int) demonstrated significantly higher Peak Power (PP), with mean values of 10.43 W/kg, compared to 9.69 W/kg for national-level athletes (Nat) (t-statistic: -2.83, p-value: 0.0096). Mean Power (MP) also tended to be higher in the international group, averaging 7.71 W/kg, in contrast to 7.36 W/kg for the national group, though this difference did not reach statistical significance (t-statistic: -1.40, p-value: 0.1746). No significant differences were observed in Maximal Oxygen Uptake (VO2max), with the international group averaging 59.48 ml/min/kg and the national group 61.70 ml/min/kg (t-statistic: 0.76, p-value: 0.4595). Lactic Acid Maximum (LA max) levels were slightly higher for international competitors, averaging 12.21 mmol/L, compared to 11.38 mmol/L for their national counterparts (t-statistic: -0.90, p-value: 0.3786). Moreover, a significant correlation was found between MP and lactate ($r = 0.57$, p-value: 0.0028), and a negative correlation was observed between lactate levels and VO2max ($r = -0.66$, $p < 0.05$). These findings underscore the importance of anaerobic power in the high-performance profile.

CONCLUSION: Our findings suggest that while aerobic capacity provides a fundamental foundation for kayaking performance, the ability to generate and sustain high-intensity anaerobic power, as evidenced by higher peak power and post-exercise lactate levels, is a more significant determinant of success at the highest competitive levels. These insights underscore the importance of tailored training programs that focus on enhancing anaerobic power outputs to improve performance among elite kayakers.

THE RELATIONSHIP BETWEEN STRENGTH, BODY COMPOSITION AND 500 M SPRINT KAYAK PERFORMANCE

KLITGAARD, K., DE ZEE, M., KRISTIANSEN, M.
AALBORG UNIVERSITY

INTRODUCTION: Kayaking, as a dynamic sport, demands a blend of strength, power, and endurance [1]. A range of physiological and biomechanical factors, such as body composition, muscle strength, stroke rate, stroke force, and paddling technique, shape sprint performance in kayaking [2]. However, past research has often isolated individual aspects of kayak sprint performance, overlooking the intricate interplay among these variables. Furthermore, past research has been centered around short distances (≤200m) and 1000m. With more disciplines in the Olympic program being centered around the 500m event/distance, a greater understanding of the strength demands of 500m performance is needed. This study investigates the relationship between body composition, strength, and performance in kayaking over a 500m distance.

METHODS: 30 trained female (6) and male (24) kayakers were recruited with a mean age of 20.69 ± 5.27 years, body mass of 80.14 kg ± 9.62, and height of 1.79 ± 0.07 m. They performed a 500 m on-water kayak test with a standing start. During this test, the following variables were recorded: paddle force (E-kayak, AP-Lab), footrest force, and kayak velocity. On a different day, 1RM tests were carried out in the bench press, bench pull, pull up, and a specific kayak strength measured on a custom-made single-arm machine (3). Body composition was measured on a DEXA scanner (GE Lunar iDXA). A partial least squares regression analysis model was used to assess the relationship between the independent variables and the dependent variable (on-water kayak test).

RESULTS: The regression model revealed notable relationships between 1RM strength variables(Bench-pull, Bench-press and Pull-ups), total lean mass, torso, and arm lean mass, along with paddle forces, as evidenced by their high VIP (Variable Importance in Projection) values ranging from 1.162 to 1.307. Furthermore, the same variables showed a solid relationship to 500m performance when looking at loadings, with values ranging from 0.252 to 0.285.

CONCLUSION: The high VIP value and loading values suggest that these variables are important predictors of the outcome. 1RM strength variables(Bench-pull, Bench-press, and Pull-ups), total lean mass, torso and arm lean mass, and paddle forces are the best predictors of 500m on-water kayak performance. A wider array of factors appears to affect the 500m sprint than the 200m sprint, where 1RM strength emerges as the most significant predictor of performance.

QUANTIFYING CLIMBING ENDURANCE: ANALYSIS OF INTERMITTENT ISOMETRIC FOREARM MUSCLES' CONTRACTIONS ACROSS VARIED HOLD DEPTHS

EXEL, J., LEDROIT, C., MUSIL, C., GÁSPARI, A., BACA, A., KAINZ, H.
UNIVERSITY OF VIENNA

INTRODUCTION: Isometric finger endurance is key for climbing performance [1, 2] and methods for estimating forearm muscles' aerobic capacity is an important tool to optimize training organization. Previous work has proposed a method for determining this capacity, based on percentages of maximal voluntary isometric contractions of the forearms and fixed hold depth [3]. However, climbing often present variety of holds sizes, shapes, and depths to challenge climbers' skill abilities while performing and understanding the relationship between climbers' tolerance to exercise in different hold depths is still unknown. A first step towards that is determining an assessment protocol that can exhibit a real change in performance instead of a change consistent with the measurement error. Thus, the aim of this study was to assess the consistency of the force measurements in the test-retest of an intermittent exercise of isometric body-weight dead hangs to exhaustion performed in 4 different hold depth.

METHODS: Twenty climbers (28.7□7.2 years, 175.9□7.9 cm height, 67.7□9.9 kg weight, 21.4□1.6 IRCRA scale climbing ability level) visited the lab in four occasions for testing, with a minimum interval of 48 hours between sessions. The test consisted of intermittent isometric dead hangs to exhaustion, with a 7:3 s work:relief ratio in one of the 2 pairs of holds with different depths: 10 - 30 mm, and 15 - 20 mm. The sequence of hold pairs was assigned randomly for the 1st and 2nd sessions, and repeated in the retest. An instrumented hang board, with adjustable hold depths and 2D strain gauge sensors, captured applied force (N), time-to-exhaustion (TTE), and total work (TW).

RESULTS: The average vertical force and TTE for both sessions was 320±0.1 N - 24.5±2.1 s for 10 mm, 326±0.6 N – 55.5±2.2 s for 15 mm, 377±1.6 N – 109.7±0.05 s for 20 mm, and 331±0.5 N - 158±16.9 s for 30 mm. Interclass Correlation Coefficient (ICC average [95% CI]) showed good to excellent consistency for all depths across sessions (10 mm, 15 mm, 20 mm and 30 mm, considering force (0.92[0.80-0.97], 0.99[0.99-0.99], 0.98[0.97-0.99], 0.99[0.98-0.99], respectively), TTE (0.77[0.41-0.91], 0.93[0.84-0.97], 0.92[0.80-0.97], 0.91[0.76- 0.96], respectively), and TW (0.81[0.40-0.94], 0.94[0.82-0.9], 0.90[0.70-0.96], 0.91[0.74-0.97], respectively).

CONCLUSION: These results show a potential of this protocol to be used in future investigations to unveil the relationship between steady state work rate of the forearm muscles during isometric contractions and hold depths. This is an important initial step towards understanding the effects of different hold depths in climbers' maximum work that the forearm muscles can maintain for an extended duration without fatigue (critical force [CF]) and characterizing the energy store component which is depleted above CP, first proposed by [3].

CARDIOPROTECTION INDUCED BY INTRADIALYTIC EXERCISE IN AN OPEN-LABEL, PROSPECTIVE RANDOMIZED TRIAL: A REGIONAL WALL MOTION ANALYSIS AND CLINICAL DETERMINANTS

MAUFRAIS, C., JOSSE, M., PATRIER, L., ISNARD, M., GRANDPERRIN, A., TURC-BARON, C., NOTTIN, S., CRISTOL, J.P., OBERT, P.
AVIGNON UNIVERSITY

INTRODUCTION: Cardiovascular diseases are present in more than 50% of patients with End-Stage Kidney Disease (ESKD). Hemodialysis (HD) is a life-saving treatment but it also induces LV regional wall motion abnormalities (RWMAs) that leads to LV systolic dysfunction due to a transient myocardial ischemia, a phenomenon well-known as myocardial stunning. Such repetitive ischemic insults are widely recognized to be important in the pathogenesis of cardiac failure and contribute to the excess cardiovascular mortality in this population. Therapeutic strategies to mitigate cardiovascular disorders associated with HD are therefore mandatory. Acute intradialytic exercise (IDE) has the exciting potential to be cardioprotective in patients with ESKD. However, studies analyzing its effect on myocardial stunning are scarce, and include a small number of patients and some methodological bias. We aimed to explore 1) the impact of IDE on the regional occurrence of RWMAs in a large cohort of exercise-naïve subjects receiving HD and 2) the benefits of the cardioprotection induced by IDE according to the clinical characteristics of patients.

METHODS: In this prospective, open-label, two-center randomized crossover trial, 72 stable patients performed 2 HD sessions in a random order: a standard HD (HD-CONT) and a session incorporating 30min of aerobic exercise (HD-EX). Echocardiography was performed immediately before HD (T0) and at peak stress of HD (i.e. 30 min before HD ending, Tpeak) during each session. An 18-segment model was used to identify RWMAs, defined as a 20% reduction in longitudinal strain at Tpeak compared to T0. Myocardial stunning was confirmed for patients who developed at least 2 RWMAs at Tpeak.

RESULTS: IDE significantly reduced the number of RWMAs during HD-EX compared to HD-CONT (estimated difference: 1.1segment, 95%CI: 0.33/1.90, p=0.009). There was a base-to-apex benefits gradient of IDE with the greatest reduction in RWMAs observed at the apex during HD-EX when compared to HD-CONT. Overweight patients had a decrease in RWMAs during HD-EX compared to HD-CONT (HD-CONT: 7.1±3segments, HD-EX: 5.3±3segments; p<0.001) whereas we observed no significant difference for normoponderal patients (HD-CONT: 6.5±3.5segments, HD-EX: 6.2±3.5segments; p=0.99).

CONCLUSION: We confirm that IDE limits the myocardial stunning induced by HD. Using a regional analysis for the first time in the literature, we exposed a reduction in the number of RWMAs occurring during HD-EX compared to a standard session with greater benefits observed at the apical level. The most relevant clinical characteristic related to the decreased myocardial stunning induced by IDE was the ponderal status of patients. Overweight individuals presented a greater decrease in RWMAs compared to normoponderal patients.

Further studies are needed to fully elucidate the mechanisms underlying the benefits of IDE on the regional myocardial function and better identify the clinical factors that determine the degree of cardioprotection.

KEEP HYPERTENSION "OUTDOOR" FROM YOUR CARDIOVASCULAR HEALTH

PAPALE, O., FESTINO, E., DI ROCCO, F., FUSCO, A., CORTIS, C.

UNIVERSITY OF CASSINO AND LAZIO MERIDIONALE

INTRODUCTION: Hypertension is the primary risk factor for global mortality. Physical activity (PA) has been established as an effective treatment for hypertension, leading to reductions in Systolic BP (sBP), a response known as Post-Exercise Hypotension (PEH). Although gym-based exercise is the most common form of PA, there has been a growing trend towards outdoor activities. Considering the limited research on its benefits, this study aims to compare the sBP response and the PEH following indoor (laboratory) and outdoor activities.

METHODS: 11 subjects (age:24.3±1.1 years; BMI: 23.5±2.6 kg/m2) completed an outdoor activities on a selected hike and participated in a laboratory-based treadmill test, incorporating both uphill and downhill walking. During the laboratory test, subjects self-selected their speed to replicate their pace from the outdoor activities. The initial 2-min stage was set at 0% grade. The grade then increased by 2% at each 2-min stage during the uphill phase until subjects reached 95% of their estimated maximum heart rate (HRmax) or volitional fatigue, followed by a decrease of 2% at each 2-min stage during the downhill phase until it returned to 0% grade. During both sessions, sBP was measured 15-min before (PRE) and 30-min after (POST). Means (M) and standard deviations of PRE and POST sBP, along with PEH (difference between PRE and POST sBP measurements), were determined. Repeated measures mixed models assessed the effects on sBP, treating subjects as a random effect and measurement times (PRE and POST) as fixed effects. Paired t-tests compared PEH between field and laboratory settings, with statistical significance set at p<0.05.

RESULTS: Significant reductions were observed in the field session (length: ~3800m, max slope: 19%, M slope: 5.3%, M duration: 41:86min, M HRmax: 84%) between PRE (127.8 ± 7.8 mmHg) and POST (110.2 ± 8.6 mmHg) sBP measurements, resulting in a PEH of 17.6±6.7mmHg (p<0.001), and in the laboratory session (length: ~2800m, max slope: 25%, M slope: 8.1%, M duration: 40:00min, M HRmax: 92%) between PRE (124.5±8.6mmHg) and POST (106.1±6.4mmHg) sBP measurements, resulting in a PEH of 18.4±10.7mmHg (p<0.001). No significant (p=0.80) differences in PEH (M difference: 0.9 ± 11.3 mmHg) were found between the sessions.

CONCLUSION: Our findings align with the existing literature, confirming the positive effect of PA on reducing BP. These results suggest that the beneficial effects of PA on sBP could be replicated, and potentially even enhanced, by exercising in outdoor environments. This enhancement is linked to subjects achieving a lower internal load during outdoor activities, suggesting a stronger cardiovascular protective effect, even with similar exercise characteristics. Outdoor activities replicate traditional PA benefits and provide a potentially more sustainable and beneficial approach to improving overall health by reducing cardiovascular stress.

IS IT MORE TIRING TO CARRY OUT RESUSCITATION PROCEDURES WITH THE PATIENTS BED AT A HEIGHT OF 80 CM OR 42 CM?

MORGADO, J.P., BHUDARALLY, M.1, FEBRA, C.2, ATALAIA, T.3, PEREIRA, H.1,2, GUERRA, J.3, PALMEIRA, A.1, ALEIXO, P.1

1- CIDEFES -UNIVERSIDADE LUSÓFONA 2- HOSPITAL DA LUZ, LISBOA, PORTUGAL 3- ESCOLA SUPERIOR DE SAÚDE DA CRUZ VERMELHA PORTUGUESA LISBOA, PORTUGAL

INTRODUCTION: The guidelines of the American Heart Association and the European Resuscitation Council (ERC) (Perkins et al., 2021) for improving Cardiopulmonary Resuscitation (CPR) procedures applied to cases of cardiopulmonary arrest have recently been updated. During these procedures, chest compressions (CT) are essential to maintain continuous blood supply to the heart and brain (Chi et al., 2008). Depending on the clinical scenario, a resuscitator can perform CPR kneeling (patient on the floor outside the hospital setting) or standing (with or without a stool, with the patient on a bed in an emergency unit).

Kinematic analysis of the resuscitated patient in two situations with different bed heights (63 cm and 37 cm) revealed that there were no differences in the compression forces and their depths (Chi et al., 2008) compared. On the other hand, another study (Parent-Nichols et al., 2021) also analysed the effects of bed height on the resuscitators kinematics during standing CPR.

According to the ERC guidelines, the resuscitator who performs CT should be resuscitated at least every 2 minutes. If there is fatigue and/or less effective CT, the resuscitator should be surrendered earlier.

Our purpose was to compare the physiological impact of a Cardiopulmonary Resuscitation protocol performed with the patient on beds of different heights: 80 cm and 42 cm.

METHODS: Four certified female first aid trainers with more than 5 years experience (46.0 ± 7.48 years; height 163.1 ± 3.57 cm; 80.0 ± 4.82 kg) carried out a CPR protocol of 5 periods of chest compressions interspersed with 2 minutes of recovery in 2 scenarios with different bed heights: 80 cm (H80) and 42 cm (H42). Heart rate (HR) was monitored throughout the protocol and lactatemia was analysed during the recovery periods.

Nonparametric Wilcoxon test for related samples was used to compare mean values of H80 and H42. Statistical significance was set at $p<0.050$.

RESULTS: There was a tendency towards higher average values in response to H80 compared to H42 for blood lactate (H80: 4.81±1.97; H42: 2.93±0.67; p=0.068), HRTCavg (H80: 129.5±17.1; H42: 116.8±17.1; p=0.068), HRTCmax (H80: 139.9±19.1 ; H42: 126.3±20.4; p=0.068), FCCTmin (H80: 106.6 ±15.7; H42: 99.0±14.1; p=0.273) e HRRec (H80: 113.9±20.2; H42: 105.7±17.1; p=0.465).

CONCLUSION: Higher patient bed heights (80 cm) seem to induce more resuscitator fatigue in CPR processes than lower heights (42 cm), considering the physiological indicators of lactatemia and mean and maximum exertional HR and recovery HR.

Physiological characterisation of effort and recovery will be great tools for deepening knowledge about optimising processes during CPR.

Fitness level may be a factor to determine chest compression duration and the levels of physical function, muscle strength, mass and morphology tend to decline with ageing. Future studies may adress the impact of an exercise intervention programme on the CC efficiency and induced fatigue in first aiders.

ENDURANCE WALKING TEST: VALIDATION OF A SIMPLE AND REPRODUCIBLE METHOD TO MEASURE EFFECTS OF REHABILITATION IN CARDIORESPIRATORY PATIENTS.

LE PORCHOU, L., CHEHERE, B., SOULET, A., PAGLIA, O., SIMON, B., GIROUX-METGES, M.A., MANSOURATI, J.
UNIVERSITÉ DE BREST - CHU DE BREST - ORPHY EA 4324

INTRODUCTION: Exercise tests are routinely used to assess the evolution of exercise tolerance following a rehabilitation in patients with cardiopulmonary diseases. Among all these tests, it was previously reported that walking endurance time (the time a person is able to walk at a constant, personalized intensity) is the most sensitive endurance parameter to assess the effects of rehabilitation. Difficulty lies in the feasibility of the method: it must be quick to set up for care teams and should last less than 10 minutes. The reference method (Endurance Shuttle Walk Test [ESWT]) is time-consuming as the walking speed is determined following two Incremental Shuttle Walk Test (ISWT). In this study, we propose a walking endurance test using the average speed measured during the 6-minute walk test (6MWT) which is already performed routinely and less time-consuming. The aims of this study are (1) to compare the walking speed and the feasibility of the two methods: ESWT using the two ISWT (SWTISWT) versus ESWT using the 6MWT (SWT6MWT), (2) to compare the cardiorespiratory adaptations during the tests and (3) to assess the reproducibility and learning effect of the SWT6MWT.

METHODS: Forty-four patients (age: 64 ± 10 years) with heart failure (n=16, Left Ventricle Ejection Fraction: 41 ± 10 %) or chronic obstructive pulmonary disease (n=28, Forced Expiratory Volume in the 1st second: 53 ± 14 %predicted) were recruited from Brest University Hospital and underwent 4 visits over a 4-week period:

- Visit 1: two 6MWT,
- Visit 2: two ISWT and one ESWT using the ISWT (SWTISWT),
- Visits 3 and 4: two ESWT using the 6MWT (SWT6MWT).

For each test, endurance time, heart rate (HR), respiratory rate (RR), tidal volume (VT), minute ventilation (VE), pulse oxygen saturation (SpO2), dyspnea and fatigue (modified Borg scale) were assessed.

RESULTS: (1) The SWT6MWT showed a higher speed when compared to SWTISWT (5.1 ± 1.1 vs. 4.3 ± 0.7 km.h-1, respectively; $p<0.001$); a smaller duration (263 ± 196 vs. 995 ± 338 sec, respectively; $p<0.001$) and a higher proportion of patients with endurance time under 10 minutes (71% vs. 19%, respectively; $p<0.001$).

(2) The SWT6MWT showed a higher SpO2 when compared to SWTISWT (92 ± 4 % vs. 90 ± 5 %, respectively; p=0.006); a higher RR (32 ± 6 vs. 30 ± 5 cycles.min-1, respectively; p=0.017) and a higher dyspnea score (5 ± 1 vs. 4 ± 1, respectively; p=0.002).

(3) The four SWT6MWT, whether separated by recovery time (30 minutes) or several days, were not significantly different (p=0.820).

CONCLUSION: Using the 6MWT to personalize the endurance test intensity can be achieved for cardiorespiratory patients. The SWT6MWT seems to be a quick to set up and a feasible method with a higher proportion of patients having an endurance time under 10 minutes that of SWTISWT. The higher speed of SWT6MWT compared to SWTISWT means a higher RR and dyspnea score but also allows patients to desaturate less during their test. Finally, the SWT6MWT is a reproducible method with no learning effect.

ENDOTHELIAL FUNCTION: A COMPLEX ASSOCIATION WITH CARDIOVASCULAR RISK FACTORS, SLEEP QUALITY AND CARDIORESPIRATORY CAPACITY IN PATIENTS WITH ACUTE CORONARY SYNDROME.

HBAIEB, M.A., CHARFEDDINE, S., HAMMOUDA, O., DRISS, T., BOSQUET, L., ABID, L.
UNIVERSITY OF POITIERS

INTRODUCTION: It is widely acknowledged that normal endothelial function plays a pivotal role in conferring cardioprotective effects against ischemia-reperfusion (IR) injury following acute myocardial infarction treated by a primary percutaneous coronary intervention (PCI), thereby mitigating oxidative stress and limiting infarct size. However, endothelial dysfunction has been extensively documented in patients with cardiovascular (CV) risk factors .This study proposes a novel perspective, positing that endothelial dysfunction could be intricately linked not only with traditional CV risk factors, but also it can be associated with poor sleep quality.Consequently, this interplay might significantly contribute to the attenuation of exercise capacity.

The aim of this study was to assess endothelial function following acute myocardial infarction (AMI) treated with a PCI and investigate the link between endothelial function, CV risk factors, sleep quality and exercise capacity. Furthermore, Additionally, the study aimed to determine if endothelial function could serve as a predictive factor for future major adverse acute cardiac events (MAACE) following AMI.

METHODS: Sixty-three patients with AMI (56.21 ± 7.6 years) volunteered to participate in this study, . Endothelial function was assessed using the Endothelium Quality Index (EQI) . Sleep quality was evaluated using both actigraphy and the PSQI (Pittsburgh Sleep Quality Index) questionnaire. Exercise capacity was quantified through the 6-minute walking test (6mwt).

RESULTS: Endothelial dysfunction (ED) was evident, as indicated by an EQI of 1.4 ± 0.7. Furthermore, ED was notably influenced by CV risk factors such as low physical activity level, age, and smoking. A significant correlation was found between EQI and both sleep efficiency ($r = 0.340$; $p = 0.006$) and PSQI score ($r = -0.533$; $p < 0.001$). Additionally, a strong association was observed between endothelial function and the results of the 6mwt ($r = 0.291$; $p = 0.021$). Furthermore, during a follow up period (near 4 months) following PCI, MAACE were observed in patients with severe endothelial dysfunction only.

CONCLUSION: In summary, this inquiry shows potential in revealing a complex interplay among impaired endothelial function, CV risk factors, sleep quality, and cardiorespiratory capacity during post-myocardial infarction recovery. Findings of this study may emphasize the importance of enhancing sleep quality and advocating for an active lifestyle as modifiable elements to enhance endothelial function, which can be regarded as a prognostic tool subsequent to AMI, ultimately contributing to improved clinical outcomes

PATELLOFEMORAL PAIN IN YOUNG GYMNASTS

STEINBERG, N., ELBAZ, L., BAR-SELA, S., DAR, G., NEMET, D., ELIAKIM, A.
LEVINSKY-WINGATE ACADEMIC COLLEGE

INTRODUCTION: Patellofemoral pain (PFP) is prevalent in high impact athletes. In gymnastics, intensive physical activity, including the repetition of extreme movements apply loads and strains to the lower extremities. The combination of high-impact forces and long practice hours along pubertal development increased the concerns for PFP in competitive young gymnasts. Our aims were to investigate the prevalence of PFP in rhythmic, acrobatic and artistic gymnasts; and to look at the relation between PFP and anatomical features (such as maturation, joints ROM, bone strength and muscle strength) in young gymnasts from those three different disciplines.

METHODS: Data was collected via screening of 274 (aged 11.8±1.9 years) rhythmic, acrobatic and artistic compatetive gymnasts. They were asked to complete the Tanner questionnaire and to report their date of birth and menarche status. Each gymnast was assessed for anthropometrics, bone strength, muscle-strength (ankle plantar-flexors/dorsiflexors, knee extensors/flexors and hip abductors/adductors), hypermobility (using the Beighton 9-Point Test) and joints range of motion (ROM) (passive ankle dorsi flexion/plantarflexion, active hip extension, hip abduction, anterior split, posterior split and active trunk extension). Each gymnast underwent a physical examination conducted by the same physical therapist (specializes in sports medicine) for PFP.

RESULTS: 21.5% of the gymnasts had PFP, with significantly higher prevalence among artistic gymnasts (33.3%) compared to rhythmic gymnasts (21.4%) and acrobatic gymnasts (10.0%) ($p=.008$). No significant differences were found in age, menarche status and pubertal stages of gymnasts with and with no-PFP ($p>.05$). Univariate ANOVA showed discipline X PFP interaction for h/week of training this year ($F(2, 267)=3.647$, $p=0.027$). Logistic regressions showed that increased h/week of training last year (OR=1.062) and reduced muscle-strength [knee extensors (OR=0.853) and hip abductors (OR=0.673)] were significantly associated with PFP.

CONCLUSION: The prevalence of PFP was high, especially among artistic gymnasts. Impact of training and reduced knee and hip muscle strength were associated with PFP in young gymnasts. The knowledge acquired from this study can be utilized by all those involved in gymnastics, as a means of designing injury-prevention programs and for modifying train-

ing programs for gymnasts' specific body structures and current developmental stages. This combined with an increased understanding of factors related to injuries can help reduce musculoskeletal injuries among young female gymnasts.

ACTIVE PHYSIOTHERAPY IS SUPERIOR THAN PASSIVE PHYSIOTHERAPY FOR PATIENTS WITH CHRONIC KNEE PAIN: A 12-MONTH FOLLOW-UP OF A RANDOMIZED TRIAL

CUI, X., ZHAO, P., GUO, X., WANG, J., HAN, T., ZHOU, X., YAN, Q.
CHINA INSTITUTE OF SPORT SCINENCE

INTRODUCTION: Knee pain disrupts daily life, and functional impairments contribute to neuromuscular imbalance, a key factor in musculoskeletal pain. Effective treatment of chronic pain requires understanding the intricate interplay between systems and structures, transitioning from a singular structural focus to addressing functional impairments. Active physiotherapy (AP) adopts a patient-centered approach, using active movements to integrate sensory-motor information for functional recovery and pain relief. Passive physiotherapy (PP) involves direct therapist intervention and passive treatment. However, research on the therapeutic potential of AP and PP for chronic musculoskeletal pain is limited. This study aimed to determine whether AP is superior to PP in improving knee function over a 12-month follow-up period in patients with knee pain.

METHODS: 87 patients with symptomatic and radiographically confirmed knee pain were randomly assigned to either 3 months of Active Physiotherapy (AP) (n=44) or Passive Physiotherapy (PP) (n=43). The AP protocol integrated Mulligan Mobilization (MWM), active myofascial release technique, therapeutic exercises, with a focus on muscle balance, neuromuscular control, and coordination. The PP protocol consisted of physical agents therapy (such as laser therapy, microwave therapy, ultrasound therapy, and so on) and passive manual therapy. The primary outcome was the change from baseline in the Knee Injury and Osteoarthritis Outcome Score-4 domain version (KOOS4). Key secondary outcomes included pain intensity (VAS), quality of life (SF-36), and functional performances (40-meter fast walk and 6-minute walk test), measured at different intervals. Intention-to-treat and per-protocol analyses was performed. Linear mixed-model analysis was utilized.

RESULTS: Over a 12-month follow-up period, knee function improved in the AP by 20.5 ± 13.5 and in the PP by 14.2 ± 12.5. The overall between-group difference was 6.2 points (97.5% CI, 1.8 to 10.7; P = 0.007). The mean difference of the VAS was -5.3 mm (95% CI, -8.7 to -1.8; P=0.003), favoring AP. No difference between groups was observed in SF-36. AP group exhibited substantial improvements in all functional performance variables compared to the PP group (P < 0.05). Adverse events: 4 in AP, 7 in PP, with additional knee pain outpatient visits most frequent (2 in AP, 6 in PP).

CONCLUSION: Active physiotherapy demonstrates superiority in improving function and alleviating pain in patients with knee pain. These findings underscore the considerable therapeutic value of active physiotherapy for chronic knee pain treatment.

PAIN WITHOUT GAIN? ASSESSING PAIN PERCEPTION AND JUMP HEIGHT AFTER ACTIVE AND PASSIVE FOAM ROLLING: A CROSSOVER RANDOMIZED CONTROLLED TRIAL

HEINKE, L.N., JAVANMARDI, S., ZEMKE, J., RAPPELT, L., KNICKER, A., FREIWALD, J., NIEDERER, D., BAUMGART, C.
UNIVERSITY OF WUPPERTAL

INTRODUCTION: In the last decade, foam rolling (FR) gained popularity as a pre-exercise tool, improving range of motion and performance [1]. However, the specific effects of active (AFR) and passive (PFR) FR remain unclear. This study aims to explore how AFR and PFR affect pain perception and jumping performance.

METHODS: In a crossover RCT, 20 participants (10 men and 10 women) underwent both AFR and PFR sessions on their anterior thigh and calf muscles on two separate days. Prior to each treatment, participants engaged in a 5-minute warm-up on a stationary bicycle. Afterwards, each leg was treated twice for 3 minutes. Vertical force during AFR was measured with a force plate, and a custom constant-pressure rolling device was used for PFR, with pressure individualized to 32.1 ± 1.5% of body weight [2]. Countermovement jump (CMJ) performance was assessed before and after warm-up, and post-FR treatment. Pain perception, using the visual analog scale (VAS), was evaluated for both AFR and PFR during treatments. Two-factor (treatment x time) rANOVA`s using statistical parametric mapping (SPM) were employed to compare body weight-normalized vertical force data for the CMJs. SPM analyses were executed in Python using the open-source package spm1d, and further statistical analyses were calculated using R 4.2.2.

RESULTS: Jumping performance showed a moderate, but not statistically significant group × time interaction effect (p = .078, ηp2 = .126). Pairwise comparison indicated a small reduction from POST1 to POST2 for both AFR (27.2 ± 6.1 cm to 25.9 ± 5.7 cm; SMD = .225) and PFR (27.1 ± 5.9 cm to 25.1 ± 5.5 cm; SMD = .343). Furthermore, at POST2, a trivial difference was observed between AFR and PFR (SMD = .145). The rANOVA`s of SPM showed no interaction effects. AFR and PFR rolling pressure analysis revealed statistically significant higher forces on the thigh in AFR (291.0 ± 74.3 N) compared to PFR (223.7 ± 35.1 N) (SMD = .822). Pain perception was significantly higher in PFR (6.1 ± 2.1) compared to AFR (3.9 ± 2.4) (SMD = .975).

CONCLUSION: Both rolling conditions reduced the jumping performance. Surprisingly, participants rated PFR more painful than AFR, despite AFR applying substantially higher pressure. Speculatively, the non-contracted musculature in PFR may allow greater modulation of muscle and tissue stiffness, contributing to more pronounced negative effects on performance. It is noteworthy that in both conditions, the applied pressure could be twice as high as typically used in occlusion studies [3]. A concern for practical application is that, when comparing AFR and PFR, even higher mechanical pressure in

AFR does not lead to increased pain perception compared to PFR. Adverse effects on connective tissue, nerves, blood vessels, and bones should be critically considered if both treatments are improperly used.

INPATIENT VERSUS OUTPATIENT REHABILITATION FOLLOWING TOTAL KNEE ARTHROPLASTY

MAU-MÖLLER, A., EL-AARID, N., BEHRENS, M., STÖCKEL, T., BERGSCHMIDT, P., BADER, R., TOHTZ, S., MITTELMEIER, W., JACKSTEIT, R.

UNIVERSITY OF ROSTOCK

INTRODUCTION: Studies on the effectiveness of inpatient and outpatient orthopaedic rehabilitation have not yet differentiated their analyses with respect to certain orthopaedic diseases. This is the first study on the effectiveness of both rehabilitation programmes in a specific orthopaedic population (total knee arthroplasty [TKA] patients) with a focus on functional motor performance.

METHODS: Forty-two patients were allocated to a 3-week inpatient (n = 26) or outpatient (n = 16) rehabilitation program. Measurements were performed 1 day before discharge from the hospital (pre-test) and 3 months after TKA (post-test). Outcome measures included physical activity over a period of 7 days, i.e. number of steps (primary outcome variable) and number of sit-to-stand transitions. Secondary outcomes included knee pain, knee joint swelling, active and passive maximal knee flexion and maximal knee extension range of motion, timed up and go performance, stair climbing performance, joint position sense at 30° and 50° of knee flexion, gait performance and long-term memory representation of the gait.

RESULTS: The outpatient group performed a higher number of steps (mean difference: 14840; 95% CI: 6844 to 22835; $P < 0.001$) and sit-to-stand-transitions (74; -11 to 158; $p = 0.086$) during the first 7 days of rehabilitation. They also showed a lower error during the knee joint repositioning test at 30° (-7.7°; -12.4° to 3.2°; $p < 0.001$) and 50° (-5.5°; -10.0° to 1.0°; $p < 0.010$) of knee flexion and better stair climbing performance (-6.1s; -12.3s to 0.1s; $p = 0.004$) at post-test.

Correlation analyses between the functional outcome measures revealed moderate and strong positive relationships between the number of steps and sit-to-stand transitions ($r = 0.48$; $p = 0.003$) and between stair climbing and timed up and go performance ($r = 0.68$; $p < 0.001$).

CONCLUSION: The outpatient rehabilitation group showed (i) significantly higher physical activity during the first 7 days of rehabilitation, (ii) better proprioceptive accuracy and stair climbing performance 3 months after TKA, (iii) no significant group-differences in pain, swelling, range of motion, timed up and go performance, gait performance or long-term memory representation of the gait and (iv) correlations between functional outcome measures.

The associations between functional measures are not surprising, but – together with the finding of higher physical activity and better motor performance during and following outpatient rehabilitation – the present study underlines the relevance of physical activity for regaining and/or retaining motor performance in the early postoperative phase following TKA. Our findings suggest that, besides standard physiotherapy, everyday physical activity should be promoted during inpatient rehabilitation. Thus, outpatient rehabilitation is a suitable alternative for patients who can be treated in either an inpatient or an outpatient setting.

UPHILL TREADMILL RUNNING AND JOINT MOBILIZATION IMPROVE DYNAMIC STABILITY AND ANKLE DORSIFLEXION RANGE OF MOTION IN YOUNG ADULTS WITH CHRONIC ANKLE INSTABILITY: A FOUR-ARM RANDOMIZED CONTROLLED TRIAL

LAO, Y.

TSINGHUA UNIVERSITY

INTRODUCTION: The objective of this trial was to observe the effect of uphill treadmill running and the combined effect of uphill running plus ankle joint mobilizations on subjective feeling of instability, dynamic postural control and ankle dorsiflexion range of motion in young adults with chronic ankle instability(CAI).

METHODS: A randomized, four-arm, pretest-posttest design was implemented. After screening, a total of 76 CAI patients were randomly allocated among four groups: the combined uphill running and joint mobilization group(URJM), the uphill running alone group(UR), the joint mobilization alone group(JM), and the control group. Participants in the URJM group and UR group received 20 minutes per session, three treadmill training sessions per week throughout a 4-week program. Ankle joint mobilizations were provided three sessions a week for 4 weeks for the participants in the URJM group and JM group. The outcome measures included the Cumberland Ankle Instability Tool (CAIT) assessing subjective feeling of instability; the Y-balance test (YBT) in anterior, posteromedial (PM), and posterolateral (PL) directions assessing dynamic postural control; the weight-bearing lunge test and non-weight-bearing ankle dorsiflexion degree in half circle goniometer (NWBG) assessing ankle dorsiflexion range of motion. Linear mixed models were used to test differences between groups, with baseline outcome values serving as a covariate for adjustment. The effect size (Cohen's d) will be calculated to evaluate the magnitude of difference among groups.

RESULTS: There were statistically significant effects after isolated UR, JM or URJM on CAIT compared with the control group($p<0.01$). All the mean difference and the lower 95% CI were greater than the minimal clinically significant difference

of CAIT(3 scores), supporting the clinical efficacy. For the outcomes of dynamic postural control, there were statistically significant effects after isolated UR, JM or URJM on YBT-PM and YBT-PL compared with the control group($p<0.01$). For ankle dorsiflexion range of motion, participants in URJM group had a significantly greater improvement in NWBG than those in UR($p=0.021$), JM($p=0.028$) and the control group($p=0.000$).

CONCLUSION: A 4-week uphill treadmill running program can improve the subjective feeling of instability and dynamic postural control in young adults with CAI. Compared to uphill running alone or joint mobilization alone, their combined application can better improve non-weight-bearing ankle dorsiflexion range of motion. This effect may help improve inadequate ankle dorsiflexion preceding heel strike, a known risk factor for ankle sprains in CAI individuals. Clinical implications: The uphill running program mentioned in this study is a form of exercise therapy that can be autonomously undertaken by CAI patients. Clinicians and physical therapists may consider incorporating uphill running into the rehabilitation protocols for CAI patients.

OP-SH19 Physical Education and Pedagogics/Teachers

"FEELING SAFE" WHILE TEACHING GYMNASTICS IN PHYSICAL EDUCATION CLASSES? A QUALITATIVE EXPLORATION OF CHALLENGING FACTORS

ROHLEDER, J., UNGEHEUER, A., SCHAEFER, J., VOGT, T.
GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: Although gymnastics is named as an essential movement domain within western Physical Education (PE) curricula, research indicates too little relative teaching time compared to other movement domains [1]. Approaching German circumstances and possible causes (e.g., in university PE teacher studies), this study aims to explore challenging factors perceived by German PE teachers regarding the teaching of gymnastics classes.

METHODS: Using a literature-based interview guide, semi-structured interviews of six PE teachers and trainee teachers (age: 40.0±18.7 years, female: one, male: five) with different professional and gymnastics-specific experiences were recorded. Qualitative content analyses served for combined deductive and inductive category coding by two coders using MAXQDA. Based on deductively detected main categories (MC; i.e., framework, teaching, apparatus, spotting, and safety), subcategories were inductively identified revealing a substantial inter-coder agreement (Krippendorff's alpha: 0.80) [2].

RESULTS: Identified subcategories assigned to MC-framework comprised time, stock of equipment, class size, staff shortage and curriculum. MC-teaching included methodology, pupils' and teachers' prerequisites, conscientiousness, uncertainty, risk-taking, pupils' motivation as well as teaching content material. MC-apparatus covered the apparatus setup and defects, whereas the statements concerning MC-spotting addressed the application of spotting by pupils and teachers as well as the teaching of spotting skills. MC-safety differentiated the subcategories injury risk and prevention as well as apparatus handling.

DISCUSSION: According to Robinson et al. (2020), insufficient time which was mostly associated with apparatus setup was mentioned most frequently as a main challenge caused by the school-related framework. Regarding gymnastics-specific teaching at school, the findings indicate a lack of basic organisational knowledge concerning the structure of a gymnastics class. This is with respect to declining motor skills of children [3]. Furthermore, the trusting involvement of pupils in setting up the apparatus and spotting gymnastics movements challenges the duty of supervision as a sole teacher. With this, teachers' uncertainties when applying spotting techniques are less about the technical implementation, but more in the fear of getting reproached for encroaching behaviour.

CONCLUSION: The present findings motivate to steadily rethink those challenging factors that contemporary university teaching can address. Intending a mixed-method approach, further research aims to survey the practical relevance of current gymnastics-specific PE teacher studies at German universities based on the present study's preliminary findings.

WEB-BASED INTERVENTION PROGRAM TO FOSTER NEED-SUPPORTIVE BEHAVIORS IN PHYSICAL EDUCATION TEACHERS AND PARENTS: A CLUSTER-RANDOMIZED CONTROLLED STUDY TO SUPPORT STUDENTS' PA-RELATED OUTCOMES

MEERITS, P.R., TILGA, H., KOKA, A.
UNIVERSITY OF TARTU

INTRODUCTION

The global trends of insufficient physical activity (PA) levels among children and adolescents underscore the imperative to identify ways to encourage their PA behavior. Both parents and teachers play a crucial role in shaping the health behaviors of children. Therefore, we developed and tested two online need-supportive interventions based on self-

determination theory, for parents and physical education (PE) teachers. The interventions consist of video lectures about need-supportive techniques that parents and PE teachers can use when interacting with children to support their intrinsic motivation towards leisure-time PA.

METHODS

We recruited 115 children (Mage = 12.47 ± 0.68, boys = 55, girls = 60) and one parent for each child. Students were cluster-randomized by school into four study groups (PE teacher training; parent training; combined PE teacher and parent trainings; control). Respective of the group, PE teachers and parents were assigned to either participate in a 4-week need-supportive intervention program or continue teaching and parenting as usual. Children completed questionnaires on psychological measures and self-reported PA pre-intervention, post-intervention, and one month after the intervention. Repeated measures ANOVAs were conducted to test the unique and combined effects of the interventions.

RESULTS

Students in the combined study group showed significantly higher perceived autonomy support from parents at one-month follow-up compared to students in either intervention alone and the control group. Contrary to expectations, the combined study group also demonstrated significantly higher perceived controlling behavior from teacher and external regulation in PE classes at one-month follow-up.

As the effect of these interventions may be moderated by the baseline PA level, we conducted additional analyses to examine whether the interventions were more effective for the sub-group of students with relatively low levels of PA at baseline. Results showed that combined study group demonstrated significantly higher levels of intrinsic motivation in PE, and perceived autonomy and competence support from parents at one-month follow-up compared to students in either intervention alone and the control group. Students in both PE teacher and parent alone intervention groups demonstrated a decline in perceived controlling behavior from PE teacher compared to the control and combined study groups at one-month follow-up.

DISCUSSION

When PE teachers and parents are involved simultaneously in supporting children's psychological needs, the children feel more autonomy support from their parents at follow-ups. Furthermore, results indicated that these interventions may be more beneficial for children who have lower PA levels at the outset.

Future research should replicate the interventions with a larger number of participants. Also, future intervention studies are advised to select children who are currently especially low in PA.

INCLUSION IN PHYSICAL EDUCATION TEACHER TRAINING PROGRAMMES - RECORDING THE ATTITUDES AND SELF-EFFICACY EXPECTATIONS OF PROSPECTIVE PHYSICAL EDUCATION TEACHERS WITH REGARD TO INCLUSION IN SCHOOLS

DESAIVE, C., KEYE, I.

HUMAN SCIENCES

Introduction

Pro-inclusive attitudes and inclusion-related self-efficacy expectations are important prerequisites for the implementation of inclusive Physical Education and are considered determinants of success for the implementation of inclusive schooling for pupils. Targeted support in this regard should already be provided during university teacher training (Willems & Meyer 2019). As Caprara et al. (2006) showed, positive attitudes and self-efficacy expectations of teachers have a positive influence on pupils learning success. Following on from this, the present study records and analyses the inclusion-related attitudes and self-efficacy expectations of Physical Education Teacher Trainees at Otto von Guericke University Magdeburg.

Method

In this Analysis n=70 (m= 46, f= 24) Physical Education Teacher Students were included. The students age is from 18 to 24 years. The survey was conducted using the SACIE-R "Sentiments, Attitudes and Concerns about Inclusive Education - Revised" with 15 items and the TEIP "Teacher Efficacy for Inclusive Practice" with 18 items.

Results

No significant difference was found between the Bachelors and Masters students in the overall analysis of the results (p=.39). The mean value comparison of the genders also revealed no significant difference in the SACIE-R (p= .91), nor in the comparison of the results of the survey using the TEIP questionnaire (p= .59). In the subscale "Concerns about the implementation of inclusive teaching", a significant difference was found between the Bachelors and Masters degree programmes (p=.02, d= 0.5).

Discussion

The subscale Concerns (concerns regarding the implementation of inclusive teaching) shows a significant difference between Bachelor and Master students. The results show that Bachelor students are more likely to have concerns about inclusion in schools and inclusive Physical Education. Students state that they hardly have the necessary knowledge and skills to teach in Physical Education to learners with disabilities. Physical Education Teacher Students also rate their skills in designing individualised learning tasks for learners with disabilities as rather mediocre. A stronger integration of inclusive learning opportunities and courses in teacher training programmes is therefore becoming increasingly important.

PHYSICAL EDUCATION COOPERATING TEACHERS AND THEIR UNDERSTANDING OF MENTORING PRESERVICE TEACHERS

AMORIM, C., RIBEIRO-SILVA, E.
UNIVERSITY OF COIMBRA

Introduction

Preservice teachers (PSTs) spend time in real classrooms during school placement to familiarise themselves with the intricate requirements of their future careers. Numerous academic works emphasise the importance of the cooperating teacher (CT) during the school placement, and PSTs' professional identities are shaped by their interaction and support from the CT (Izadinia, 2016). PSTs are required to learn about a range of topics and elements related to the teaching profession from CTs. This study aimed to comprehend how CTs perceive their role as mentors and how it affected and contributed to PSTs' identity formation.

Methods

Seven CTs with 22 to 40 years of experience teaching physical education participated in this qualitative study. Semi-structured interviews were conducted to collect data, and the questions centred on mentoring. The CTs were given preference in terms of time and location for the interviews. The interviews were audio recorded and manually transcribed with all personally identifiable information removed to protect the participants' privacy. We performed thematic content analysis and to identify trends in the data, we conducted a comparative horizontal analysis. Categories driven by the data were: PST role, PST characteristics, pros and cons of mentoring, PST strengths and weaknesses, PST teacher identity and professional relationships.

Results and discussion

CTs understand that PSTs should start their school placement by being available for a year of learning and want to mentor PSTs who are predisposed to it. CTs value PSTs with commitment to the school placement and availability to learn, which were also seen as strengths. The disparity in training and lack of personal investment in their formation process were seen as weaknesses. The role of CT is seen as positive for its challenge and keeping up to date. The negative side of mentoring relates to the amount of work that CTs must do. CTs believe that PSTs have good preparation in didactic-pedagogical knowledge but not in the different sports. Half of the participants believe that PSTs develop a teacher identity throughout the school placement and the rest believe that it depends on the person and their previous experiences. Despite some conflicts that sometimes arise, CTs maintain a friendly and professional relationship with their mentees.

Conclusion

This study set out to study the role of the CT as a socialisation agent. We understand that CTs place a strong humanistic focus on the personal development of the PSTs in addition to acquiring essential teaching skills. If we desire a certain socialisation, we must also value these CTs and CTs perceptions of their own mentoring should be made clear.

DOES THIS MAKE SENSE? ASSESSING MACHINE LEARNING APPLICATIONS FOR SPORT RELATED USE-CASES

HECKSTEDEN, A.
UNIVERSITÄT INNSBRUCK

Today, machine learning is self-evident part of many life domains. Impressive performance in some areas together with objectivity and scalability may lead to the impression that data-driven approaches are generally superior to other ways of generating knowledge and competence (e.g. "normal" statistics or experience- based learning). This apparent edge is particularly attractive in competitive sport where "AI" based applications have become pervasive. While understanding and evaluating technical details is beyond the reach for most sport scientists and practitioners, it is possible to gauge the potential suitability of machine learning for a specific use-case and critically scrutinize performance claims. To begin with, it is important to keep in mind that the performance of data driven approaches relies (among other things) on two critical

requirements: (i) Large amounts of precedents (many previous cases to learn from) and (ii) An informative - not just large - set of explanatory variables (that is, the explanatory variables jointly explain most of the outcome). Only if these requirements are met, one can hope to identify regularities that generalize beyond the training data. Note that neither a vast panel of explanatory variables (as e.g. in "omics" approaches), nor a sophisticated, highly-flexible machine learning algorithm (e.g. a deep neural network), nor a large number of repeated measurements (e.g. from wearables) can make up for a limited number of precedents. Therefore, in many sport-related use-cases, a misfit between the model complexity required for useful performance and the number of available precedents ("data scarcity") poses hard limits to the performance of data-driven approaches. Why is this "hard" limitation is not recognized more generally? Arguably, challenges of unambiguously verifying model performance play a major role. First and foremost, complex an / or probabilistic outcomes (e.g. recovery need or injury occurrence), which are common in sport, do not allow for a direct comparison of model output with the (later) observed ground truth. Moreover, model performance may differ dramatically between training set, cross-validation, out-of-sample, and out-of-population validation. While successful practical application requires model performance with new cases, data scarcity increases the risk of spuriously high performance on the training data ("overfitting"). Therefore, verified out-of-sample performance is crucial for sports practice and should always be reported / requested. Moreover, consciously scrutinizing the plausibility of claimed performance based on the predictability of the outcome, the set of explanatory variables and common sense remains important (e.g. near perfect prediction of contact injuries in team sports based on GPS data alone). This talk will illustrate the above considerations based on practical examples and provide suggestions for fitting machine learning approaches to sport-related use-cases

UNDERSTANDING PARAMETER INFERENCE VERSUS PREDICTIVE INFERENCE WHEN APPLYING MACHINE LEARNING MODELS

REIN, R.
GERMAN SPORT UNIVERSITY COLOGNE

Standard statistical practices in sports science research typically involve the estimation of unobservable model parameters based on a specific data model. Subsequently, inferences usually connected to a hypothesis testing framework about model parameters are performed to identify data generating processes and possible causal relationships. In general, linear model approaches instantiated for example through Analysis of Variance type of analyses represent the majority of analysis approaches across sports science disciplines. Accordingly, model driven hypotheses tests using a frequentist theoretical approaches form the main epistemological framework to interpret research results and assess their importance. However, with the increasing application of machine learning approaches (ML) to sports science data this approach is overly restrictive and may also lead to erroneous procedures. First, a distinction must be made between an inferential approach and a decision-making approach according to the aim of research project. ML approaches are typically much more suitable when researchers are interested in building a decision-making procedure as their strengths lie in prediction results and less on parameter inferences. ML methods therefore usually require a different approach to the analysis of the data and the interpretation and assessment of the model as many of these models act as black-boxes in contrast to standard linear models. Practices common under an inferential framework like variable selection may not only be unnecessary but may actually deteriorate performance even when less important variables are deleted. In turn, when using black-box algorithm approaches model interpretability necessarily becomes less important compared to predictive accuracy. Focusing more strongly on predictive properties has thereby the benefit of being often of direct interest to practitioners. A practitioner may not have much interest in what has been found for a specific sample but rather would like to know what would happen if new observables would be collected based on their specific sample of athletes. As the prediction error and more general model accuracy become more central for the assessment of a chosen analysis procedures like cross-validation, model stability, and model comparison and concepts like bias-variance trade-off and overfitting become much more important compared to traditional goodness-of-fit tests and parameter inferences. Unfortunately, knowledge and best-practices about these procedures and their specific requirements are not commonly taught at sports science institutions which at best hampers the application of ML to sports science data and at worst leads to erroneous applications. Thus, when adopting more algorithm centered machine learning in contrast to traditional model centered approaches different requirements have to be met by the researchers to ensure that their conclusions are truly supported by their data.

THE DATA SCIENTIST AND THE COACH: A LONG LASTING MARRIAGE IF DONE RIGHT

KEMPE, M.
UNIVERSITY OF GRONINGEN

Using Machine Learning (ML) to synthesize the vast amount of data enabling coaches, trainers, and support staff to make educated decisions might be the most influential use in sports practice. By now, a professional sports team monitors their athletes extensively, recoding variables of training prescription and performance (external load), as well as the physiological and mental strains of these training sessions (internal load). Next to that, they also perform regular performance testing and record individual variables like age, injury history, growth spurt, etc. The complexity and possible interactions of these variables are hard to grasp which is why Robertson made the argument to install decision support systems to create recommendations for practitioners based on "historical" data [1] using ML. Such a system creates simplified variables and/ or visualization by synthesizing various information to make better-informed decisions. Especially in terms of athlete monitoring and injury prevention, different approaches were introduced in the last decade to serve this purpose. A recent review found eleven studies that used different data sources and ML algorithms to predict injuries [2].While the quality of

the implementation of the ML algorithms in these papers was good compared to earlier reviews in this field [3], the overall quality of the evidence just ranked from very low to moderate. While seeming accurate, these approaches aren't endorsed by practitioners. Therefore, this talk will give recommendations to design an approach that is helpful, useful and accepted by coaches and the supporting staff using ML. The outline is given by an example of a use case of Dutch National Short track team, applying a readiness to perform prediction to adapt daily training prescriptions. To enable more sport scientist to apply such an approach and facilitate reproducibility, appropriate reporting as well as data and code sharing should be stimulated. This means open science principles, as highlighted by Bullock et al. [4], should be stimulated in these publications. This includes using reporting guidelines like TRIPOD and adhering to FAIR data principles. Thus, this talk will give an outline on how to setup an ML project for practical implementation in a way that could also serve as a blue-print for other sport scientist.

IS-MH08 Moving Forward! Advancements in Physical Activity, Exercise and Eating Disorders

BODY SYSTEMS AND BIOPHYSIOLOGICAL ADVANCEMENTS IN EDS

FERNANDEZ DEL VALLE, M.

UNIVERSIDAD DE OVIEDO

Eating disorders impact all systems of the body. Among them, the nervous system is the most studied in EDs with neurobiology being one main area receiving extensive attention. Historically, brain function has been examined through cerebrospinal fluid samples. However, over the past decades, in vivo brain imaging has made possible the study of the structure, composition, activity, and biological function of the brain and food-related behaviors. Beyond neurobiology, scattered research has exposed significant biophysiological alterations at multiple levels in EDs like altered body composition, dysbiosis of the gut microbiota, epigenetic changes, or impaired inflammatory and metabolic responses. An individual who engages in maladaptive movement during an ED exacerbates dysfunction of all body systems and, as a consequence, undermines treatment efforts by reducing the probability of full recovery. Adapted exercise unfolds as a crucial tool to modulate several of these alterations, however, clinical teams lack of resources to help them manage maladaptive movement (a critical ED symptom). In addition of having a better understanding of these alterations and the degree to which body systems affected, a deeper knowledge of the impact of movement (maladaptive and healthy) could aid medical teams, exercise professionals and patients. It is of great importance, therefore, to look at EDs from a more complex perspective that includes the biophysiological component. This talk will provide an overview of the main neurobiological alterations in EDs. Following, we will offer a comprehensive view of the bio-physiology and body systems affected on these disorders including areas of interest such as muscle, fat and bone tissue, microbiota, epigenetics, or inflammation. In addition, this talk will also seek to clarify the connections between the biophysiological alterations and the modulatory potential of healthy movement in EDs.

COMPULSIVE EXERCISE: UNDERSTANDING EXERCISE OBSESSIONS AND COMPULSIONS

SOLFRID, B.

UNIVERSITY OF SOUTH-EASTERN NORWAY

Difficult relationships with movement have long plagued the field of eating disorders (EDs). Starting in the 19th century, clinicians and researchers have documented such behavior in their patients and attempted to term this phenomenon and determine a corresponding conceptualization. Unfortunately, a consensus has yet to be reached on how to conceptualize difficult relationships with movement. In part, this is due to the lack of knowledge and understanding about both the complexity cognitions and behaviors. Recent advancements have identified exercise obsessions without compulsions across various population, making the cognitions about exercise relevant also for the sedentary persons. This adds to the complexity of how to identify and manage complicated relationships with movement across populations (i.e., athletes, persons diagnosed with EDs or persons experiencing disordered eating). This is of particular importance because up to 80% of patients engage in maladaptive movement over the course of their EDs. Further yet, individuals with and without EDs can experience facets of maladaptive movement. In this presentation, we will give an update on recent advancements in the conceptualization of compulsive exercise and present the term "maladaptive (bodily) movement", which reflects both quantitative and qualitative aspects. We will also explore their presentation across populations and activity types (i.e., incidental physical activity, exercise, and sports). Finally, we will outline how the qualitative facets of maladaptive movement can present in the non-ED population and present the implications for the general population. Together, this presentation will offer knowledge on different aspects and conceptualizations of maladaptive movement. It will provide information on the tools and instruments used to identify and manage such behavior in both athletic and clinical populations.

THE SAFE EXERCISE AT EVERY STAGE (SEES) GUIDELINE, UPDATES, AND IMPLEMENTATION

QUESNEL, D.
UNIVERSITY OF TORONTO

Eating disorders (EDs) are a group of mental health disorders that cause serious harm to both physical and psychological health and well-being. Although treatment advancements have been made, ED outcomes are often less than ideal as high levels of drop-out, partial responses to available therapies, and elevated relapse rates characterize ED patients. A factor that has been known to interfere with ED treatment and recovery is maladaptive movement, which reflects quantitative and qualitative features of one's relationship with activity across modalities (i.e., incidental activity, sport, exercise). Engaging in maladaptive movement before, during and after ED treatment can aggravate negative treatment outcomes. However, clinicians don't feel they have the knowledge and tools to address this transdiagnostic ED symptom. Further complicating this arena is the incidence of EDs and maladaptive movement in athlete populations. For athletes, their careers, financial wellbeing, education, and identity often rely on their ability to perform in the sport. However, the incidence of an ED and maladaptive movement can make sports engagement difficult, if not impossible, for some. It leaves coaches and clinicians with the difficult task of helping athletes return to their sport if achievable. The Safe Exercise at Every Stage (SEES) and Safe Exercise at Every Stage- Athlete (SEES-A) guidelines were developed to support clinicians and exercise professionals in managing movement during treatment for an eating disorder. Since 2019, the SEES guidelines have garnered international recognition and helped private and public ED treatment programs enhance how they address movement with their clients. Clinician training based on the SEES guideline demonstrated the ability to improve clinician self-efficacy in addressing maladaptive movement during treatment. The SEES team has continued to remain up to date with the current literature and integrated it into the SEES and SEES-A guidelines. This talk will provide an overview of the SEES and SEES-A guideline and how they have been updated over the last five years. We will continue by guiding health professionals through step-by-step instruction on using the guidelines in clinical practice with athletes and the general population. Finally, an open discussion will engage participants in reviewing any questions or difficulties they have had in navigating maladaptive movement in EDs within research and clinical contexts.

Oral Presentations

OP-PN18 Fatigue I

CAN MUSCLE FATIGUE OR PEDALING TECHNIQUE EXPLAIN THE VO2 SLOW COMPONENT DURING CYCLING?

MACDOUGALL, K., ABOODARDA, S., WESTERGARD, P., MACINTOSH, B.
UNIVERSITY OF CALGARY

INTRODUCTION: During constant power cycling in the heavy and severe domains, the steady-state VO2 is delayed or prevented due to the VO2 slow component (SC). The rising oxygen uptake has been assumed to represent a progressive loss of muscle efficiency, resulting primarily from skeletal muscle fatigue, however evidence for a causal relationship is equivocal. Notably, it has also been demonstrated that alterations in pedaling technique may occur during fatiguing cycling exercise. If these alterations impair cycling efficiency, this could represent a moderating factor between the development of fatigue and the increase in oxygen cost observed with the SC. However, little is known about the existence of pedaling technique adjustments during fatiguing cycling exercise in association with the SC. Therefore, the purpose of this study was to explore the association between the VO2 SC and skeletal muscle fatigue, and the impact that changes in pedaling technique may have on the development of the VO2 SC.

METHODS: Eleven participants completed an incremental exercise test to determine lactate threshold, followed by constant power trials to exhaustion at 10% above lactate threshold (power output 194 ± 55W). Utilizing femoral nerve stimulation and instrumented pedals, muscle fatigue was assessed, along with oxygen uptake, quadriceps oxygenation, electromyography (EMG), and pedal force components. To explore the temporal relationship between muscle fatigue and the appearance of the SC, Pearson's correlation coefficient was calculated between the relative reductions in twitch force across the first 2.5 min of exercise and the time of onset of the SC. To explore the association between the SC and alterations in pedaling technique, repeated measures correlations between physiological and mechanical variables were estimated at both a group and individual level.

RESULTS: There was no significant correlation between the time of onset of the VO2 SC and initial reductions in twitch force ($r = -0.076$, $p = 0.852$). At a group level, the SC (387 ± 172 ml/min at peak) was significantly correlated with quadriceps twitch force ($r = -0.48$, $p < 0.001$), root mean square EMG ($r = 0.18$, $p = 0.016$), and muscle oxygenation ($r = -0.50$, $p < 0.001$), as well as with pedaling mechanical variables such as peak total downstroke force ($r = -0.16$, $p = 0.022$), minimum total upstroke force ($r = -0.15$, $p = 0.029$), and upstroke index of effectiveness ($r = 0.18$, $p = 0.012$). However, there was large interindividual variability for all these correlations. At an individual level, repeated measures correlations between twitch force and the SC ranged from -0.03 to -0.87, while correlations between the SC and some pedaling mechanical variables were seen to be as high as 0.80 for some individuals.

CONCLUSION: From the heterogeneity of the data, we question a direct causal link between fatigue and the SC, and suggest that alterations in pedaling technique may also be a factor in its development.

THE MAGNITUDE OF PERFORMANCE AND PERCEIVED FATIGABILITY IS DEPENDENT ON INTENSITY AND EXERCISED MUSCLE MASS

ABOODARDA, J., ABOODARDA, S.J., ZHANG, J., MACINNIS, M.J., IANNETTA, D.
UNIVERSITY OF CALGARY

INTRODUCTION: The extent of performance and perceived fatigability varies based on the volume of exercised muscle mass (1,2). However, no study to date has explored this effect across the entire intensity spectrum. Accordingly, this study aims to investigate alterations in muscle contractile function, central voluntary activation and perceived responses to single-leg (SL) and double-leg (DL) cycling tasks performed within four intensity domains.

METHODS: Eleven males (29±4 years) performed SL and DL cycling to task failure in the moderate (MOD), heavy (HVY), severe (SVR), and extreme (EXT) intensity domains, as characterized by gas exchange threshold, respiratory compensation point, and maximal aerobic capacity from a DL ramp incremental test. SL cycling was performed at 60% of the power output corresponding to DL trials. Voluntary and evoked contractions, including 5s MVC of the dominant knee extensors combined with superimposed 100 Hz doublets (Db100) and resting Db100, 10 Hz doublets (Db10), and single twitch electrical stimuli of the femoral nerve were performed at baseline, immediately upon task failure, and following 1, 4, and 8 min of recovery. Perceived fatigue, leg pain, dyspnea, and effort were collected during trials. Two-way repeated measures ANOVAs with Bonferroni post hoc examined 2 modes × 4 timepoints within each domain.

RESULTS: Time to task failure was similar between SL and DL cycling in all domains. MVC declined more following SL in SVR (SL vs. DL: -41±12% vs. -31±15%; P=0.036) and HVY domains (-42±16% vs. -30±18%; P=0.011). Also, peak twitch force declined more following SL at SVR (-49±13% vs. -40±7%; P=0.048) and HVY domains (-31±12% vs. -22±10%; P=0.007). Voluntary activation declined more following SL than DL at HVY (-20±15% vs. -9±10%; P=0.008). Dyspnea was greater following DL at HVY (7±3 vs. 6±3; P=0.031), SVR (8±2 vs. 6±2; P=0.001), and EXT domains (7±2 vs. 5±2; P=0.025), whereas ratings of fatigue, pain, and effort were similar between exercise modes.

CONCLUSION: These findings suggest that metabolic perturbations within smaller muscle mass exercise (e.g., SL vs. DL cycling) can result in greater impairments in muscle contractile function within the SVR and HVY domains. However, the impairment in muscle function may be exacerbated for DL cycling within the MOD domain. Also, except for greater dyspnea, perceived responses between exercised muscle masses did not show any difference between domains. Collectively, these findings indicate that the modulatory effect of muscle mass on the extent of performance and perceived fatigability is exercise intensity-dependent.

THE EFFECTS OF HYDROGEN GAS ON REPEATED SPRINT PERFORMANCE IN HEALTHY ACTIVE ADULTS—A RANDOMIZED CONTROLLED CROSSOVER TRIAL

CHEN, W.T., LIN, W.C., HSU, T.C., YOU, W.T., WU, C.L.
NATIONAL CHUNG HSING UNIVERSITY

INTRODUCTION: Molecular hydrogen has been suggested to have antioxidation and anti-inflammatory properties which may serve as ergogenic aids for sport and exercise performance. Studies have investigated the potential effects of molecular hydrogen, mainly given as hydrogen-rich water, on endurance performance and muscle damage. However, little has been known in terms of the effects of inhaling hydrogen gas on high intensity intermittent exercise (HIIE). Thus, the purpose of current study was to explore the potential effects of acute inhalation of hydrogen gas on high intensity repeated sprint performance.

METHODS: Fourteen healthy active males (age:22.9±5.4yrs, height:177.8±6.3cm, weight:70.5±8kg) were recruited to participate in this randomized, double-blinded, placebo-controlled, crossover study. Subjects were randomized to inhale either hydrogen gas (H2) (gas generation rate was 1.5L/min, containing 70% hydrogen and 30% oxygen) or normal gas (placebo, ambient air) for 30 mins (including a 10-min warm up), before performing the HIIE test. They were asked to return to the laboratory, after a 7-day washout period, to inhale the other gas in a crossover fashion. The HIIE test, conducting after gas inhalation, comprised 15x6s all-out repeated sprints (20s active recovery between sprints) on a cycle ergometer, and the work load was fixed at 9% of body weight. Blood samples were collected at baseline, pre-test and post-test to analyze blood lactate and arterialized venous blood gas. Rate of perceive exertion (RPE) were recorded at the end of the test. Peak power (PP), mean power (MP), minimum power (MinP), work done (WD), cadence (rpm), fatigue index (FI) and decrement score (Sdec) were recorded during the test. Data were analyzed by using repeated measures ANOVA, and were presented as mean±SD.

RESULTS: Significant group by time interactions were found in venous blood partial pressure of oxygen (PO2) (p=.012), partial pressure of carbon dioxide (PCO2) (p=.012), total carbon dioxide content (tCO2) (p=.013), base excess (BE) (p=.016), bicarbonate (HCO3) (p=.013) and standard bicarbonate (stHCO3) (p=.022), but not in pH and blood lactate. Furthermore, blood BE (-9±2.8 vs. -10.6±2.9 mmol/L, p<.05) and stHCO3 (17.2±2 vs. 16.1±2 mmol/L, p<.05) concentrations were both found higher at post-test in the H2 trial, which corresponded to the trend of lower variations in BE (p<.05), HCO3 (p<.01) and stHCO3 (p<.05) while performing the HIIE in the H2 trial. As for the sprint performance, no significant differences were observed in PP, MP, MinP, WD, rpm, FI, Sdec and RPE between trials.

CONCLUSION: The results suggested that pre-exercise acute inhalation of H2 might facilitate a more effective buffering system in blood, which might be explained by the relatively moderate variations in BE and HCO3 during exercise. However, the enhanced magnitude of buffering capacity was not able to alter blood pH and lactate production, which, taken together, resulted in trivial effects on the repeated sprint performance.

THE LINK BETWEEN SLEEP, MENTAL FATIGUE AND CAFFEINE USE: EVIDENCE FROM A RANDOMIZED CROSSOVER TRIAL FEATURING OVER 90 PARTICIPANTS

HABAY, J., EZZY, Q., ARENALES ARAUZ, Y.L., PATTYN, N., VAN CUTSEM, J., ROELANDS, B.

VRIJE UNIVERSITEIT BRUSSEL , ROYAL MILITARY ACADEMY , RESEARCH FOUNDATION FLANDERS

INTRODUCTION: Both sleep and mental fatigue (MF) influence cognitive and physical performance [1, 2]. However, while they are theorized to share similar effects and mechanisms, not much is known about the link between sleep and MF variables. Moreover, caffeine is said to influence both states, but no research has yet included caffeine use as a confounding variable.

METHODS: Ninety-nine healthy individuals (54 male, 32.7 ± 8.7 y, 175.1 ± 9.9 cm, 70.0 ± 11.7 kg, 48.4 ± 9.4 ml/min.kg) were included in this randomized crossover trial. Participants visited the lab three times (familiarization, intervention (INT) and control (CON)) and were required to either perform a 45 min Stroop task (INT) or watch a documentary (CON). The level of MF was quantified using a visual analogue scale (MVAS). A GoNoGo task (cognitive performance) and cycling time trial (physical performance) were used to quantify the behavioral effects of MF. Sleep variables included quality, quantity, chronotype and sleepiness. Caffeine use was measured using the revised caffeine consumption questionnaire. A one way ANCOVA and regression analyses were used to explore the links between all variables.

RESULTS: There was a significant rise in MF as evidenced by MVAS values (MF = 69.0 ± 18.5 AU; CON = 26.4 ± 17.6 AU; $p<0.001$; $d = 1.9$). MF negatively impacted Go reaction time (MF = 382.4 ± 33.3 ms; CON = 369.5 ± 32.2 ms; $p <0.001$; $d = 0.6$), Go accuracy (MF = 98.1 ± 1.6%; CON = 98.7 ± 1.2%; $p<0.001$; $d = 0.4$), and NoGo accuracy (MF = 88.1 ± 9.8 %; CON = 91.2 ± 7.4%; $p < 0.001$; $d = 0.4$). Distance in the time trial showed a trend to significance (MF = 12.6 ± 1.8 km; CON = 12.7 ± 1.7 km; $p = 0.078$; ES = 0.2). The one way ANCOVA showed no influence of chronotype on MF variables. Moreover, only two regression models showed a significant link between MF and sleep, with an increase in MVAS leading to an increase in sleepiness ($p = 0.040$; Adj. $R2 = 0.03$), and a decrease in sleep quality leading to a worsening of reaction time ($p = 0.035$; Adj. $R2 = 0.04$). Two variables (sleep quantity ($p = 0.099$; Adj. $R2 = 0.02$) and sleepiness ($p = 0.120$; Adj. $R2 = 0.02$)) showed a trend to significance, with an worsening of both leading to a higher effect of MF on time trial distance. Caffeine usage had no influence on the performed analyses.

CONCLUSION: The results of the present study show almost no relationship between sleep, MF and caffeine variables. Possible explanations for the lack of relationship are specific differences in physiological mechanisms and the limited variability of sleep data. Therefore, future research is necessary to gain further insights into sleep, MF and their internal connections.

EFFECT OF MUSCLE DAMAGE ON EFFICIENCY AND THE CARIOPULMONARY RESPONSES TO CYCLING

BROWNSTEIN, C., HORNER, D., JEFFRIES, O.

NEWCASTLE UNIVERSITY

INTRODUCTION: The effect of eccentric exercise-induced muscle damage (EIMD) on cycling efficiency are unclear. While some studies report a reduction in economy during cycling with EIMD (Marcora et al. 2008), others report no change (Twist et al. 2009). This study assessed the effect of EIMD on gross and delta efficiency and the cardiopulmonary responses to cycling.

METHODS: 21 recreational athletes performed 3 × 5 minute stages of cycling at 70%, 90% and 110% of the gas exchange threshold (GET) under control conditions (Control) and 24 h following a bout of damaging eccentric exercise (Damage). Efficiency, cardiopulmonary and vastus lateralis electromyographic responses, as well as rate of perceived exertion (RPE) were assessed during the last 2 minute of each stage. Damage was assessed via changes in knee extensor maximal voluntary contraction (MVC) and potentiated twitch responses (Qtw,pot). A reliability control was also performed to assess the reliability of gross and delta efficiency, in order to assess whether any change in these measures as a result of muscle damage was beyond typical error.

RESULTS: EIMD resulted in a reduction in MVC and Qtw,pot of ~25%. A 0.5-0.6% absolute reduction in gross efficiency across all work rates was found for Damage relative to Control ($p < 0.001$). However, there was no change in delta efficiency ($p = 0.513$). Concurrently, root-mean-squared EMG was 5-6% higher during Damage than Control, with RPE also higher for Damage ($p < 0.001$). Regarding the cardiopulmonary responses, an intensity-dependent increase in ventilation was found with Damage at 90% and 110%, but not 70% GET. Similarly, an increase in ventilatory equivalents for oxygen and carbon dioxide were intensity-dependent, and were only increased during Damage at 110% GET. The reliability analysis showed good to excellent reliability of gross efficiency (ICCs 0.89-0.96 across work rates), and poor reliability for delta efficiency (ICC = 0.24).

CONCLUSION: These results demonstrate the EIMD reduces gross efficiency. The concurrently higher vastus lateralis EMG activity indicates that reductions in muscle efficiency were likely responsible, at least in part, for reductions in gross efficiency. However, delta efficiency was unchanged, which could relate to its poor reliability hindering the ability to detect change. The study also demonstrates intensity-dependent hyperventilation when cycling with EIMD, which might relate to the higher central command, as indicated by the higher EMG and RPE. These results provide new insight into the effects of EIMD on the physiological responses to cycling.

IS-BM03 Reticulospinal functioning, its measurement and adaptation to resistance training

AN INTRODUCTION TO THE RETICULOSPINAL TRACT: ANATOMY, FUNCTION AND MEASUREMENT

KIDGELL, D.

MONASH UNIVERSITY

The lecture explores the anatomy and function of the corticospinal and reticulospinal tracts, and it discusses the application of transcranial magnetic stimulation (TMS) and other neurophysiological methods for the activation of neurons within each tract. Additionally, the lecture provides a concise overview of potential measurements that can be conducted in both human subjects and non-human primates. It also includes a discussion of the current methodological limitations, along with a cautionary note. Associate Professor Kidgell draws from the ongoing and as-yet-unpublished research conducted in his laboratory, as well as prior studies conducted by other research groups. Relevance: The lecture enhances comprehension of the reticulospinal tract, elucidating its anatomical location and function in relation to the more widely recognized corticospinal tract. It also probes the mechanisms through which the reticulospinal tract exerts its influence during muscle contraction. Furthermore, this lecture serves as a foundational precursor to the subsequent two lectures. Target audience: Primary interests will be from biomechanists and neurophysiologists, with secondary interests from physiologists and physiotherapists.

RETICULOSPINAL TRACT FUNCTIONING AND ADAPTATION IN NON-HUMAN PRIMATES

WALKER, S.

NEWCASTLE UNIVERSITY

This lecture covers the ground-breaking discoveries on reticulospinal tract functioning from the lab of Prof. Stuart Baker. Dr Walker will disseminate recent findings from strength training studies in non-human primates led by first author Dr. Isabel Glover. Here, he presents data recorded from muscles, primary motor cortex and the reticular formation in chronically implanted monkeys performing different strength contractions. These results provide proof-of-concept for human studies. Dr. Walker will also briefly outline possible future applications of the knowledge gained from this research. Relevance: Currently, the most convincing evidence of reticulospinal contribution to high force production and adaptation to resistance training is derived from Dr. Glover's research. Her papers are integral to focused interest on this topic. Dr. Walker's lecture will bring this work into greater attention within the field of exercise science, whereas the primary notoriety is within neuroscience currently. This lecture leads to a natural progression into lecture 3, where humans are studied using various non-invasive measurement techniques. Target audience: Primarily neurophysiologists, as well as medical science fields (such as neurologists and physiotherapists).

RETICULOSPINAL ADAPTATION THROUGH STRENGTH TRAINING IN HUMANS

HU, N.

UNIVERSITY OF JYVÄSKYLÄ

Strength training, as the primary exercise mode for increasing force production capacity, is a keen focus of this lecture. Dr. Hu provides evidence of enhanced reticulospinal functioning from chronic strength training. The lecture presents a possible (non-invasive) measurement battery to examine reticulospinal functioning and adaptation in humans, drawing on recent experience of Dr. Hu and her collaborators who have shaped these test protocols. Relevance: Evidence of reticulospinal facilitation and adaptation in humans is presented, where methodological honing, as well as current limitations are discussed. This lecture primarily consists of unpublished and/or recently published data. Dr. Hu shares the latest research findings from the lab of Dr. Walker, which will encourage future randomized controlled trials to be performed. Target audience: Primarily biomechanists and neurophysiologists. However, attendance is expected from physiotherapy, strength and conditioning, and training and testing.

INTRODUCTION: Cardiorespiratory fitness (CRF), a strong predictor of overall health and longevity, typically declines with age, increasing the risk of chronic diseases in older adults.1 Home-based high-intensity interval training (HIIT) potentially offers a practical and accessible method to improve CRF. However, objectively measured adherence levels and subsequent effectiveness of home-based HIIT in older populations remain underexplored.2,3 Therefore, this study aimed to investigate adherence to a six-month home-based HIIT intervention in older adults, as well as assessing associations between various adherence metrics and the resultant changes in peak oxygen consumption (VO2peak).

METHODS: 233 healthy older adults (60-84 years, 54% female) were randomised to six-month, thrice-weekly home-based HIIT (one circuit and two interval sessions) or a passive control group. Exercise sessions were monitored with a Polar watch and logbook for objective and subjective data, respectively, and guided by a personal coach. Adherence was assessed using frequency, intensity, and duration data, and was quantified using a novel method involving metabolic equivalents (METs).4 For each metric, adherence was expressed as percentage completion relative to what was planned. VO2peak was assessed using a modified Balke treadmill protocol to volitional exhaustion. General linear regression models (GLMs) assessed between-group differences in post-intervention VO2peak, with baseline VO2peak, age, sex, and country as covariates, and group as a fixed factor. For adherence-VO2peak associations, GLMs were used with age, sex, and country as covariates.

RESULTS: The HIIT group achieved an average total of 11116±5455 MET-min (122% of the planned exercise volume). Participants completed 2.6±0.6 sessions per week (86% of planned) and spent 10.3±5.2 min per session at ≥80% of HRpeak (98% of planned), with an average session duration of 39.9±11.8 min (135% of planned). Between-group differences were observed in the pre-to-post intervention change in VO2peak (1.8 [1.2;2.3] mL/kg/min; effect size: 0.35). There was a positive association between adherence to frequency and intensity and percentage improvements in VO2peak (β=0.1 [0.0;0.2]; β=0.04 [0.00;0.07], respectively), but not duration or total MET-mins.

CONCLUSION: The findings indicate that older adults can successfully adhere to and benefit from a home-based HIIT program, achieving clinically meaningful improvements in CRF over six months. Notably, while adherence levels are crucial in designing effective exercise interventions for this demographic, the findings indicate that exceeding prescribed exercise volumes does not necessarily lead to superior enhancements in CRF.

IMPROVED SLEEP IN OLDER ADULTS THROUGH PHYSICAL ACTIVITY AND POTENTIAL UNDERLYING MECHANISMS

SCHERRER, S., EGGER, S., WICK, A., LIU, X., XIN, L., RASCH, B., LAUBER, B., TAUBE, W.
UNIVERSITY OF FRIBOURG

INTRODUCTION: Around 50% of individuals aged 60 and older experience sleep problems, and current insomnia treatments are difficult to access or have adverse effects [1]. Thus, there is urgent need for alternatives. Gamma-aminobutyric acid (GABA)-mediated inhibition is crucial for sleep [2] and older adults exhibit lower GABA levels [3]. Interestingly, balance training has been shown to enhance GABA-mediated inhibition [4]. Thus, we hypothesised that balance training would improve sleep quality in older adults.

METHODS: 60 volunteers (64-81 years old) were randomly assigned to a three-month balance intervention (> 30 sessions; BT), a three-month strength intervention (> 30 sessions; ST) or a control group, following their daily routines (CON). Before and after the three-month period, subjective sleep quality was evaluated with the Pittsburgh Sleep Quality Questionnaire (PSQI). Sleep efficiency was recorded with polysomnography (PSG) at the participant's home. During an afternoon nap in the laboratory, short- interval intracortical inhibition (SICI), a measure of the activity of GABAergic inhibitory interneurons in the motor cortex, was assessed. GABA and lactate levels in the motor cortex were determined with magnetic resonance spectroscopy. Linear mixed-effects models (LME), followed by Bonferroni-corrected paired t- tests and cohen's d effect sizes with 95% confidence intervals were calculated.

RESULTS: LME indicated a significant time effect for PSQI scores (p=.016). BT improved subjective sleep quality by -1.35 score points (d=0.58, 95% CI [0.06, 1.09], p=.046), with no change in ST (p=1) and CON (p=1). Improved sleep scores in BT

showed a trend towards a strong correlation with increased SICI at sleep onset (r =-0.59, p=.073). Furthermore, a time effect on GABA levels was revealed (p=.025). BT increased GABA levels by 22% (d=0.97, 95% CI [0.40, 1.55], p=.009), while ST (p=1) and CON (p=1) showed no change. Sleep efficiency demonstrated a significant interaction effect of group and time (p=.006): BT (p=.353) and CON (p=1) did not change significantly while ST increased sleep efficiency by 7% (d=0.71, 95% CI [0.22, 1.21], p=.022). Additionally, ST revealed a significant decrease in brain lactate level (p=.02).

CONCLUSION: Older adults showed improved subjective sleep quality along with increased GABA levels after BT. Moreover, increased GABAergic inhibition at sleep onset was associated with improved sleep scores. These findings support the idea that BT counteracts hyperarousal in the elderly brain [5]. The observed decrease in brain lactate, a biomarker of sleep [6], suggests that ST improves sleep efficiency by improving lactate metabolism, as previously shown in animal models [7].

INTRODUCTION: Aging constitutes a multifaceted and inevitable process characterized by a gradual decline in physiological functions and an escalation in health risks. Despite a significant increase in life expectancy, the achievement of healthy aging has not kept pace accordingly. This emphasizes the importance of identifying biomarkers associated with healthy aging. Thus, this study aimed 1) to cluster the study population into healthy and unhealthy aging by using machine learning methodologies, 2) to identify straightforward predictive variables for these clusters, and 3) to analyze the relationship between clusters indicative of unhealthy aging and adverse health events and conditions.

METHODS: A prospective cohort study that included 1852 older adults (>65 years) from the Toledo Study for Healthy Aging. A total of 366 variables (including physical, cognitive, and biochemical outcomes among others) were assessed using machine learning k-means clustering. Gradient boosting, area under the curve (AUC) values, and classification accuracy (CA) were used to evaluate the predictive capacity of healthy and unhealthy aging clusters. Logistic regression analyses adjusted for age, educational level, and comorbidities were used to assess the relationship between the healthy and unhealthy aging clusters and the risk of experiencing cognitive impairment, frailty, hospitalizations, and all-cause mortality over the subsequent 6 years.

RESULTS: Two clusters of healthy (C1) and unhealthy aging (C2) were identified in both men (C1= 243; C2= 565) and women (C1= 342; C2= 702). Among the 366 variables tested, relative sit-to-stand power, loss of memory in the last two years, and habitual gait speed collectively exhibited excellent predictive capacity for healthy and unhealthy aging in both older men and women according to the AUC values (0.850 in men and 0.875 in women) and CA (0.819 in men and 0.792 in women). After 6 years of follow-up, older adults in the unhealthy aging cluster exhibited a higher risk of experiencing cognitive impairment [OR (95%CI) = 4.7 (1.8, 12.3) in men and 2.9 (1.3, 6.3) in women], frailty [OR (95%CI) = 2.8 (1.2, 6.8) in men and 7.1 (3.3, 15.4) in women], hospitalizations [OR (95%CI) = 1.8 (1.2, 2.6) in men and 2.0 (1.4 , 2.8) in women] and all-cause mortality [OR (95%CI) = 2.0 (1.4, 2.9) in men and 2.2 (1.5, 3.1) in women] compared to those older individuals in the healthy aging cluster.

CONCLUSION: The machine-learning method identified that relative sit-to-stand power, memory loss, and habitual gait speed were strong predictors of healthy and unhealthy aging in older adults. Those older people within the unhealthy aging cluster exhibited a 2 to 7 times higher likelihood of experiencing an adverse event or condition compared to those in the healthy aging cluster after 6 years of follow-up, emphasizing the importance of assessing and monitoring these variables to ensure healthy aging.

PHYSICAL ACTIVITY SHIFTS SIX MONTHS AFTER A SEVERE FALL – MODERATING FACTORS IN OLDER ADULTS

SCHMIDT, L., STUCKENSCHNEIDER, T., KWIECIEN, R., ZIESCHANG, T.

GERIATRIC MEDICINE

INTRODUCTION: Severe falls among older individuals are a common cause of emergency department (ED) visits, often leading to long-term consequences that impact functional independence. Little is known about the characteristics of individuals who suffer functional decline after such falls, however, a reduced physical activity (PA) may serve as an early warning sign. To date, PA has mostly been investigated in older adults with a fall cross-sectionally. Thus, little is known about which moderators e.g., age, sex, cognitive function, and depressive symptoms, influence changes in PA and to what extent. Therefore, this study aims to investigate the association between clinically relevant moderators and changes in PA in older adults, who experienced a severe fall.

METHODS: Participants were recruited from the SeFallED study following up on individuals aged 60 years or older, who presented to the ED after a severe fall without hospital admission [1]. Moderating factors were collected as part of a home-based geriatric assessment within 4 weeks after a fall (T1) and included: age, sex, BMI, cognitive function, depressive symptoms, concerns about falling, falls in the preceding 12 months, type of initial fall i.e., unrecovered or recovered, lower extremity function, gait speed, and hand grip strength. Participants' activity was quantified by assessing sedentary time using a three-axial accelerometer (activPAL4, PAL Technologies Ltd., Glasgow, UK), worn for 7 consecutive days, at T1 and 6 months after the initial fall (T2). Association of moderating factors with changes in PA were calculated using Linear Mixed Model (LMM) in R (R Core Team, 2023 Version 4.3.2, 2023-10-31).

RESULTS: The study enrolled 335 participants, among whom, so far, 208 individuals (mean age 75.6; 60–98 years; 134 females) contributed valid datasets up to a 6-month follow-up period, further data pending as follow-up continues. Preliminary results of LMM revealed a significant time effect for sedentary time with an increase of 150.1 minutes between T1 and T2 (95% CI: 111.3–188.9, $p<0.001$). Each fall in the preceding 12 months was significantly associated with an increase of 13.0 minutes in sedentary time (95% CI: 3.9 – 22.2, $p=0.005$).

CONCLUSION: Preliminary findings indicate that a decline in PA six months after a severe fall associates with the frequency of falls during the 12 months preceding the ED visit. Hence, this emphasizes the importance of enquiring falls in the ED in individuals seeking care post-fall, as it could signal potential long-term adverse outcomes. Considering the emerging healthcare challenge, posed by falls and their consequences, it is crucial to optimize risk assessments. The assessment should be realistically feasible and sufficiently sensitive to enable the implementation of tailored interventions for those with the most pressing needs – identifying prior falls may help.

THE EFFECT OF ORAL TAURINE SUPPLEMENTATION ON THERMOREGULATORY AND CARDIOMETABOLIC RESPONSES TO PASSIVE HEAT EXPOSURE

PEEL J.S., MCNARRY, M.A., HEFFERNAN, S.M., NEVOLA, V.R., KILDUFF, L.P., COATES, K., DUDLEY, E., THOMAS, A., WALDRON, M.

SWANSEA UNIVERSITY

INTRODUCTION: In hot or humid environments, there is a reduced capacity for dry or evaporative cooling, which can result in uncompensable heat stress and rises in core temperature (Tcore) [1]. Cardiovascular adjustments (e.g. elevated heart rate, cardiac output and peripheral vasodilation) attempt to meet heat loss demands by facilitating greater skin blood flow (SkBF) and occur in parallel to increases in sudomotor function [2]. An individual's ability to thermoregulate (i.e. enhanced vasodilation and eccrine sweating) and, consequently, tolerate such conditions, can be chronically or acutely modified [3]. Taurine supplementation enhances sweating onset and rate during exercise in the heat [4] and induces greater peripheral arterial vasodilation [5], but its potential role in thermoregulation at rest has not been evaluated. The current study aimed to determine the effect of oral taurine supplementation on sweating, vascular, cardiometabolic and Tcore responses during 90 min passive heat exposure.

METHODS: Thirteen, healthy, euhydrated, non-heat acclimated female (n = 2) and male (n = 11) participants (26 ± 5 years, 79.3 ± 9.6 kg) completed a 90 min passive heating protocol (38.4 ± 0.4°C, relative humidity 55.9 ± 1.9%), following eight-days of oral taurine supplementation (50 mg/kg of body mass) or placebo in a double-blind, randomised, cross-over design. Whole-body sweat loss (WBSL), local sweat rate (LSR), SkBF, cutaneous vascular conductance (CVC), brachial artery diameter and blood flow, mean arterial pressure (MAP), parameters of cardiac function, pulmonary gas exchange and Tcore were assessed. Relative % SkBF and brachial artery vasodilation (V%) were analysed during- and post-isometric handgrip exercise, respectively, at three timepoints (20, 50 and 80 min). Plasma taurine concentrations were determined from post-supplementation blood samples.

RESULTS: Oral taurine supplementation increased WBSL by 16.2% ($p < 0.049$), leg LSR by 26.6% ($p = 0.011$), SkBF by 19.3% ($p = 0.016$) and CVC by 9.3% ($p = 0.027$) compared to placebo. Post-isometric handgrip brachial artery (8.0 vs 5.8%; $p = 0.002$) and SkBF (6.3 vs 4.6%; $p = 0.020$) V% were greater in the taurine condition; however, no differences in resting brachial artery diameter and blood flow, MAP, cardiometabolic parameters or Tcore were observed ($p > 0.05$). Plasma taurine bioavailability was increased in taurine vs placebo (258 ± 55 vs 74 ± 26 μM).

CONCLUSION: Oral taurine supplementation influenced aspects of thermoregulation during passive heat exposure, with enhanced sweating and cutaneous vasodilatory responses, without affecting other parameters of cardiometabolic function. These findings have potential implications for individuals at risk of heat stress in environmental conditions that permit dry and evaporative heat dissipation.

EFFECTS OF RESISTANCE-BASED TRAINING AND POLYPHENOL SUPPLEMENTATION ON MITOCHONDRIAL BIOENERGETICS AND REACTIVE OXYGEN SPECIES PRODUCTION IN INDIVIDUALS AT THE ONSET OF AGING.

FLENSTED-JENSEN, M., WEINREICH, C.M., KLEIS-OLSEN, A.S., HANSEN, F., SKYGGELUND, N.S., PII, J.R., KARLSEN, A., DELA, F.

UNIVERSITY OF COPENHAGEN

INTRODUCTION: Aging entails a gradual deterioration in physical capabilities and cellular functions, including impaired mitochondrial function and heightened oxidative stress. Resistance training (RT) mitigates a decline in physical function, yet its impact on oxidative stress and mitochondrial function is unknown. Polyphenols (PP) possess antioxidant properties and can bolster mitochondrial biogenesis, but their effects in the elderly are relatively uncharted. This double-blinded RCT examines the individual and combined influences of RT and PP supplementation on muscle performance, oxidative stress, and mitochondrial respiration, with the hypothesis that mitochondrial respiratory capacity and H2O2 emission will increase and decrease, respectively, with an enhanced effect of combined RT and PP supplementation.

METHODS: 40 men and women (55-70 yrs) were randomized to ingest a PP supplement (700 mg/day) or placebo daily for one month (loading period). Then a 12-week supervised RT-based program (x3/wk), while continuing either PP or placebo (PLB), was carried out. Anthropometrics, muscle power and strength were measured at the study start, after loading and after RT. Muscle biopsies were obtained before and after RT, and analyzed for mitochondrial respiratory capacity (MRC) and H2O2 emission (Oroboros 2k). Here we report preliminary results of the RT (n=16 as one group regardless of PP or PLB) as unblinding will be done in June when the last subject is finished. Statistical analysis of MRC and H2O2 emission is done by two-way RM ANOVA, and other outcomes by a paired t-test.

RESULTS: RT led to increased leg maximal voluntary contraction strength (159±50 vs 178±53 Nm; $P < 0.001$), handgrip strength (39.1±12.2 vs 42.1±3.5 kg; $P < 0.01$) and sit-to-stand test reps (14.5±3 vs 16.8±3.4 reps; $P = 0.0001$), with a tendency towards higher VO2max (2382±429 vs 2464±470 ml O2/min; $P = 0.08$). Mitochondrial H2O2 emission decreased (main effect; $P < 0.05$) and MRC increased (main effect; $P = 0.02$) with RT. Lean mass was only significantly increased with RT in the male (n=9) participants (59.7±4.5 vs 60.9±4.8 kg; $P = 0.005$) with no significant change for the women (n=7)($P = 0.29$).

CONCLUSION: These results imply that resistance-based training can improve mitochondrial bioenergetics and attenuate oxidative stress by increasing respiratory capacity and lowering mitochondrial reactive oxygen species production in individuals at the onset of aging. This is of particular importance in this population, as aging is associated with impaired mitochondrial function and increased oxidative stress, which may be linked to the development of several age-related diseases. The effect of PP supplementation awaits the unblinding.

CARBOHYDRATE BUT NOT NIACIN INGESTION SUPPRESSES EXERCISE INDUCED AMPK SIGNALLING

BRADSHAW, L., MORENO CABAÑAS, A., SPELLANZON, B., BUNIAM, J., MALLINSON, J., TZINTAS, K., WAHLIN, J.P., BETTS, J.A., KOUMANOV, F., GONZALEZ, J.T.

UNIVERSITY OF BATH

INTRODUCTION: AMP-activated protein kinase (AMPK) is an important regulator of adaptations to endurance exercise. Training with low carbohydrate availability can increase AMPK activation (Bartlett, Hawley and Morton, 2015), but whether increased AMPK activation is due to low carbohydrate availability per se or due to concurrent increases in fatty acid availability/oxidation is unclear. The aim of this study was to assess the independent effects of carbohydrate and fatty acid availability on exercise-induced skeletal muscle AMPK activation.

METHODS: Eight active males cycled on three occasions for 1 hour at 95% of lactate threshold 1 with ingestion of either carbohydrate (CARB), niacin (NIACIN), or placebo (FAST) in a crossover design (11±6-day washout). After baseline breath, blood and muscle samples, participants consumed a drink (1.6 g/kg maltodextrin or placebo) and tablets (10 mg/kg niacin or placebo). Following 1 hour of rest participants cycled with further carbohydrate (0.8 g/kg/hr maltodextrin), niacin (10

mg/kg/hr) or placebo and blood and expired breath samples were collected every 15 minutes. Following exercise, a further muscle sample was obtained. Plasma was analysed for NEFA concentrations, and muscle for glycogen concentrations using the hexokinase method. Muscle protein content and phosphorylation status was assessed by semi-quantitative western blotting and expressed as the fold-change from pre- to post-exercise. Normality of data were checked by visual inspection of residuals. Differences between CARB vs FAST and CARB vs NIACIN were analysed by paired t-tests.

RESULTS: Fat oxidation was lower in CARB vs. FAST (13±8 g vs. 22±9 g, p=0.003) but there was no significant difference between CARB vs. NIACIN (15±8 g, p=0.59). There was no evidence for differences in glycogen use with CARB (58±56 mmol/kgDM) vs FAST (97±56 mmol/kgDM, p=0.27). However, muscle glycogen use with NIACIN (142±76 mmol/kgDM) was higher than CARB (p=0.01). ACCSer79 phosphorylation status (ratio p-ACC to total-ACC) was decreased with CARB (1.6±1.8 fold) vs. both FAST (2.1±2.1 fold, p=0.04) and NIACIN (2.0±0.8 fold, p = 0.02). AktSer473 phosphorylation (ratio p-Akt to total-Akt) was increased with CARB (1.7±0.6 fold) vs. FAST (1.0±0.4 fold, p<0.01), but the difference between CARB vs. NIACIN (1.7±0.6 fold) was not statistically significant (p=0.08).

CONCLUSION: These data suggest that augmented glycogen use during exercise with niacin use increases skeletal muscle AMPK signalling independent from circulating fatty acid concentrations. Therefore, low carbohydrate availability may be more important than fatty acid availability for AMPK induced adaptations to exercise.

INGESTION OF AN ANTI-LIPOLYTIC DRUG ALTERS WHOLE-BODY SUBSTRATE UTILISATION DURING BRISK WALKING EXERCISE IN OBESE INDIVIDUALS, BUT DOES NOT ALTER MUSCLE DIACYLGLYCEROL AND CERAMIDE CONCENTRATIONS

BARRETT, J.S.1, BENNETT, S.2, FORTIS, H.O.1, CUTHBERTSON, D.J.3, OWENS, D.J.1, STRAUSS, J.A.1, WAGENMAKERS, A.J.M.1, SHEPHERD, S.O.1

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Exercise increases turnover of muscle lipid pool and enhances storage of fatty acids as intramuscular triglycerides (IMTG) in healthy individuals. Obese individuals have lower rates of IMTG turnover leading to the accumulation of diacylglycerols (DAGs) and ceramides (Cer) and insulin resistance. Anti-lipolytic drug ingestion prior to exercise reduces plasma free fatty acid (FFA) concentrations and increases IMTG use. This study investigated whether plasma FFA suppression during and following exercise leads to alterations in fibre type and subcellular-specific IMTG use and muscle Cer and DAG species in obese individuals.

METHODS: In a repeated measures crossover design, ten obese (BMI >30 kg.m-2) sedentary individuals (7 M/3 F, 46 □ 10 y) performed two separate 45-min treadmill walking trials at 45% VO2max followed by 3 h recovery. For one trial, participants ingested the anti-lipolytic drug, Acipimox (250 mg), 1 h before and again immediately post-exercise. During the other trial nothing was ingested. Muscle samples were obtained at baseline, immediately post-exercise, and 3-hours post-exercise. Muscle samples were analysed by liquid chromatography tandem mass spectrometry for lipids (n=10), and transmission electron microscopy (TEM) for IMTG content (n=4). Data were analysed using a two-way ANOVA.

RESULTS: Plasma FFA concentrations were lower in the Acipimox trial compared to control (P<0.05). Mean carbohydrate oxidation rates measured by indirect calorimetry during exercise were greater in the Acipimox trial (1.21□0.46 g.min-1) compared to the control trial (1.01□0.38 g.min-1; P=0.002) and mean fat oxidation rates were greater in the control trial (0.38□0.10 g.min-1) compared to the Acipimox trial (0.28□0.07 g.min-1; P=0.009). Total muscle DAG or ceramide concentrations did not change during exercise or during recovery (P=0.34). The concentration of glucosylceramides (GluCer) 24:0 and 24:1 increased immediately following exercise in both conditions. Total lactosylceramide (LacCer) concentrations were significantly increased by exercise, as were LacCer species 20:0, 22:0 and 24:0, with no differences between conditions. Notably, exercise-induced increases in concentration of LacCer species appeared to be sustained following 3 h of recovery. Initial data demonstrates that Acipimox ingestion reduced intermyofibrillar IMTG content~ 30% from pre- to post-exercise compared to control.

CONCLUSION: Ingestion of an anti-lipolytic drug suppressed plasma FFA concentrations and altered whole-body substrate utilisation during 45-min of brisk walking in obese individuals. Although no changes in Cer were observed, we speculate that both the rate of synthesis and degradation of Cer and GluCer is increased by exercise, resulting in greater formation of LacCer. Ongoing TEM analysis to measure subcellular lipid droplet content and morphology will reveal whether increased flux through the de novo ceramide synthesis pathway is coupled to IMTG turnover.

CARBOHYDRATE PROVIDED IN DRINKS COMPARED TO GELS BETTER MAINTAINS HYDRATION STATUS AND ENDURANCE CYCLING PERFORMANCE IN THE HEAT DESPITE AD-LIBITUM WATER AVAILABILITY

REYNOLDS, K., MARKEY, K., HILLIER, Y., MEARS, S.A., JAMES, L.J.

LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Exogenous carbohydrate intake is recommended during exercise >60 min, with the format of delivery (i.e. gel vs drink vs bar etc.) not influencing the efficacy of the carbohydrate supplementation in temperate environments. During exercise in warm/hot environments, increased glycogen use, reduced gut blood flow and elevated sweat rates may make the format of carbohydrate delivery more important, particularly as there may be greater need to integrate fluid and

fuel strategies. Therefore, this study examined the effect of providing carbohydrate either in a gel or drink format on cycling endurance performance, gastrointestinal (GI) and fluid balance responses in a warm environment.

METHODS: Ten trained cyclists/triathletes (two females; 26 ± 6 y; 57 ± 9 ml/kg/min; 11 ± 4 h/week endurance training) completed VO2peak (22°C), full familiarisation and two experimental trials in 32°C. Trials involved 120 min at ~50% Wpeak (preload) and a ~15 min time trial (TT). Carbohydrate was provided every 20 min (72 g/h) either in the form of a DRINK (900 mL water/h males; 600 mL water/h females) or a GEL (12.4 mL water/h). In addition, water was available to consume ad libitum during the preload in both trials. Expired breath samples were collected at 60 and 120 min, with venous blood collected and GI symptoms measured at 0, 60, 120 min and post-TT. Plasma osmolality and volume, as well as concentrations of glucose, lactate, insulin, sCD14 and IFABP were measured in blood samples.

RESULTS: TT performance was faster in DRINK (848 ± 82 s vs 896 ± 121 s; P=0.027). There were no between-trial differences for GI temperature (Preload mean: GEL 37.90 ± 0.32°C; DRINK 37.80 ± 0.44°C; P=0.424), heart rate (Preload mean: GEL 145 ± 12 beats/min; DRINK 139 ± 11 beats/min P≥0.091), RPE (P=0.472), carbohydrate oxidation (P=0.313), GI comfort (P=0.664), or plasma concentrations of glucose (P=0.929), lactate (P=0.801), insulin (P=0.583), sCD14 (P=0.682) or IFABP (P=0.289). Sweat rate was not different between trials (P=0.651), but total fluid intake was higher in DRINK (2619 ± 720 mL vs 1363 ± 783 mL; P<0.001), despite higher ad-libitum water intake in GEL (1334 ± 783 mL vs 646 ± 606 mL; P=0.012). Thus, pre and post-TT hypohydration (pre-TT: GEL -1.0 ± 0.7%; DRINK 0.3 ± 0.9%; P=0.012; post-TT: GEL -1.7 ± 0.7%; DRINK -0.5 ± 0.8%; P=0.001) and plasma osmolality (pre-TT: GEL 292 ± 4 mOsmol/kg; DRINK 285 ± 5 mOsmol/kg; P=<0.001; post-TT: GEL 300 ± 4 mOsmol/kg; DRINK 293 ± 4 mOsmol/kg; P=<0.001) were higher in GEL.

CONCLUSION: During prolonged cycling in a warm environment carbohydrate provided in a drink format improved performance compared to carbohydrate provided in a gel. This was likely caused by the better maintenance of hydration status in the drink trial. This study demonstrates that, unlike during exercise in temperate environments, peri-exercise carbohydrate supplement format for endurance exercise (at least for cycling) might be an important factor in warm/hot environments.

ACL RUPTURES IN COMPETITIVE SKIERS: BICEPS FEMORIS FASCICLE LENGTHS AND PENNATION ANGLES OF THE INJURED AND NON-INJURED LIMB SEVERAL YEARS FOLLOWING SURGERY

TILP, M., SCHRETTNER, A., KONRAD, A., KRUSE, A., FISCHER, J., MANIEU, J., HABERSACK, A.

UNIVERSITY GRAZ

INTRODUCTION: Even years following ACL surgeries, hamstrings show reduced muscle activity and strength which are risk factors for relapsing injuries. A recent meta-analysis by Sherman et al. (2021) additionally reported structural changes like reduced muscular volume, cross-sectional area, and muscle length. Only one study (Timmins et al. 2016) investigated possible differences in fascicle lengths of the biceps femoris between ACL-injured and non-injured limbs of athletes. Estimates based on extrapolating visible parts of fascicles from ultrasound images revealed reduced total fascicle lengths and increased pennation angles in ACL-injured legs of rugby players. As the extrapolation of visible fascicles to obtain fascicle length is problematic (Franchi et al., 2021), the aim of the study was to compare fascicle lengths and pennation angles of the biceps femoris between ACL-injured and non-injured limbs of athletes by using extended field of view (EFOV) ultrasound to overcome this shortcoming.

METHODS: Eight competitive skiers (2 males, 22.0 years, 173.6 +/- 5.7 cm, 69.6, +/- 6.7 kg) with a previous ACL surgery (4.1 +/- 3.4 years ago) gave their written confirmed consent to participate in the study. Biceps femoris fascicle lengths and pennation angles to the intermediate aponeurosis were measured in the ACL-injured and non-injured limb in a resting position using EFOV ultrasound (Aixplorer, Supersonic Imaging). Due to not normally distributed data, Wilcoxon tests were applied to test for possible differences between the ACL-injured and non-injured limb.

RESULTS: Pilot data analyses revealed no significant differences in biceps femoris fascicle architecture between the ACL-injured and the non-injured limb. Fascicle lengths were 9.71+/-2.47 cm for the ACL-injured and 9.68 +/- 1.30 cm (p=0.67) for the non-injured leg. Pennation angles were 8.03 +/- 1.92° for the ACL-injured and 10.65 +/- 0.53° (p=0.06) for the non-injured leg.

CONCLUSION: Four years following the ACL surgery, biceps femoris fascicle lengths and pennation angles were not significantly different between the ACL-injured and non-injured limb in competitive skiers. This result is in contrast to previous research that reported shorter fascicle lengths and greater pennation angles 3.5 years following an ACL surgery in rugby players (Timmins et al. 2016). Differences could be due to ultrasound fascicle measurement technique (Franchi et al., 2021) but also due to surgery technique, rehabilitation procedures, and/or participants characteristics. We recommend that future research should incorporate advanced 3D techniques and homogenous and stratified participant groups based on sex and surgical technique to thoroughly investigate potential structural alterations in fascicle architecture post-ACL surgery and their relation to functional deficits.

SKIING CHARACTERISTICS ANALYSIS OF CROSS-COUNTRY SKIING SKATING TECHNIQUE USING KINEMATIC GNSS

UDA, S., MIYAMOTO, N., NAKANO, H., TAKEDA, M.
DOSHISHA UNIVERSITY

INTRODUCTION: In cross-country skiing, competitions, sub-techniques exist in both classical and skating styles. The most appropriate sub-techniques are selected according to the gradient of the track, snow conditions, skiing velocity, or the athletes own physical fitness, such as muscle power. Classification of sub-techniques throughout the course could enhance performance analysis of the athletes, in turn, improve training plan for individual athlete. In this study, we used a high-precision kinematic global navigation satellite system (GNSS) (sampling frequency 100 Hz) to identify sub-technique in skating and clarify the characteristics of each sub-technique such as velocity, cycle length, cycle frequency, and gradient used.

METHODS: Two subjects, an adult male skier and a junior high school male skier, were analyzed during a skating style time trial for 4.2 km. GNSS was attached to the skier's head. Three-dimensional positional data of latitude, longitude, and altitude of the head during the time trial were acquired from a GNSS, and identification was made based on the difference in waveform patterns of vertical and horizontal movements of the head for each sub-technique. The sub-techniques of skating were classified into four categories: V1, V2, V2a, and Turn, and waveform patterns other than the four were classified as others. The applied skiing technique, skiing velocity, and cycle time and cycle length, gradient used for each technique were analyzed using the GNSS data. Motion data during trial was taken by Go pro video camera (Go pro, Hero 9) followed by snow mobile (ski-doo), which was used to confirm match ratio (%Match) with GNSS data.

RESULTS: The %Match was high: 96.6% for V1, 98.2% for V2, 97.5% for V2a, 95.7% for Turn, and 97.1% in total. The percentage of each sub-technique used for all techniques was 25.8% for V1, 46.5% for V2, 14.3% for V2a, 13.3% for Turn 0.1% for others. The averages of skiing velocity, cycle time, cycle length, and gradient used for each sub-technique were calculated: for skiing velocity, V1: 4.05 m/sec, V2: 4.51 m/sec, V2a: 4.98 m/sec, and Turn: 5.01 m/sec; for cycle time, V1: 1.18 sec, V2: 1.09 sec, V2a: 1.41 sec, and Turn: 1.11 sec.; in cycle length, V1: 4.79 m, V2: 4.91 m, V2a: 7.10 m, and Turn: 5.55 m, in gradient used, V1: 2.71 degrees, V2: 1.01 degrees, V2a: -0.98 degrees, and Turn: -0.41 degrees.

CONCLUSION: Based on the results of our study, it is suggested that a high-precision kinematic GNSS can be applied for discriminate sub-technique and clarify the usage characteristics of each sub-technique such as velocity, cycle length, cycle frequency, and slope used during a skating style XCS race.

COMPARISON OF BIOMECHANICAL CHARACTERISTICS BETWEEN SPRINTERS AUTOREGULATORY SQUAT TRAINING AND TRADITIONAL SQUAT TRAINING

MEI, T., ZHANG, X., LI, J., LI, L.
BEIJING SPORT UNIVERSITY

INTRODUCTION: Autoregulatory Training (ART) can adjust training loads based on athletes training status. It includes Velocity Based Training (VBT) and Repetition in Reserve (RIR) based on subjective perception of fatigue (Rating of Perceived Exertion, RPE). However, there is limited research on the mechanical characteristics of these two methods. This study aimed to compare and analyze the biomechanical characteristics of sprinters in a single free squat training session using traditional Percentage-Based Training (PBT), RIR, and VBT, aiming to provide an individualized training load regulation protocol for sprinters.

METHODS: 18 male sprinters were recruited, and a randomized crossover experimental design was used for 3 randomized crossover squat training sessions (PBT, RIR, and VBT). Under an 80% 1RM load, the PBT group completed 5 sets of 5 repetitions each, the RIR group completed 5 sets of 5 repetitions each, with the load for the next set adjusted based on subjective feedback from the subjects, and the VBT group completed 5 sets of training, stopping each set when the speed decreased to 80% of the mean speed. Linear position sensors (Tendo) were used to collect mechanical indices (including Mean velocity (MV), Mean force (MF), Mean power (MP), Mean work (MW), Peak velocity (PV), Peak force (PF), Peak power (PP), Total work (TW), Mean load (ML), Mean repetitions (Reps), Total time under load (TUT), and Total time under load (sTUT)) and subjective perception (RPE) during the squat training. Performing data analysis using one-way analysis of variance (ANOVA).

RESULTS: (1) The VBT group had the fastest Mean velocity (MV) (PBT, VBT, and RIR MV: 0.53±0.05m/s, 0.58±0.05m/s, and 0.55±0.04m/s, respectively, $p<0.05$). The Peak velocity (PV) of the VBT and RIR groups was significantly faster than that of the PBT group (PBT, VBT, and RIR PV: 0.91±0.06m/s, 1.00±0.06m/s, and 0.97±0.06m/s, respectively, $p<0.05$). The Mean power (MP) of the VBT and RIR groups was significantly higher than that of the PBT group (PBT, VBT, and RIR MP: 729.39±61.23w, 800.72±82.64w, and 797.67±83.03w, respectively, $p<0.05$). The Repetitions (Reps) of the VBT group were lower than those of the PBT and RIR groups (PBT, VBT, and RIR Reps: 25.00±0.00, 24.06±0.73, and 25.00±0.00, respectively, $p<0.01$). No significant differences were found in other measurements among the three training groups. (2) There were no significant differences among the three groups in CTUT, but sTUT showed significant differences (PBT, VBT, and RIR sTUT: 61.41±2.74s, 54.68±2.04s, and 59.87±2.19s, respectively, $p<0.01$). (3) Compared to the PBT group, the RPE was lower in the VBT and RIR groups (PBT, VBT, and RIR RPE: 8.00±0.77, 7.44±0.51, and 7.72±0.67, respectively, $p<0.05$).

CONCLUSION: VBT and RIR demonstrated faster speed, greater power output, and lower subjective perception in a single free squat training session compared to traditional PBT. Additionally, their effects on time indices were different from PBT.

THE RELATIONSHIP BETWEEN FULLY TETHERED SWIMMING FORCE AND THE ESTIMATED MAXIMUM LOAD FROM SWIMMING LOAD-VELOCITY PROFILING

GONJO, T., LJØDAL, I., OLSTAD, B.H.

HERIOT-WATT UNIVERSITY

INTRODUCTION: Load-velocity profiling has been used to estimate the maximum swimming velocity (V0) and maximum load the swimmer can withstand (L0). Theoretically, L0 should be closely related to the fully tethered swimming force (Gonjo et al., 2021), which is an indicator of the ability to generate the propulsive force. However, this assumption has never been tested. Therefore, the aim of the present study was to investigate the relationship between L0 and the fully tethered swimming force.

METHODS: Thirteen male front crawl swimmers (19.14±2.46 years old, 1.838 ±0.072 m in height, 77.96±9.59 kg in body mass, and 652.31±117.66 World Aquatics point) performed a set of sprint semi-tethered swimming protocol consisting of three 25 m trials with three external loads, as well as three 10-second fully tethered swimming trials, in front crawl. Both semi-tethered swimming and fully tethered swimming sets were conducted with 1080 Sprint (1080 Motion, Lidingö, Sweden). The resistance load was set to 30 kg for fully tethered swimming trials. As this load was much higher than the typical estimated maximum load (about 22 kg) in front crawl swimming (Gonjo et al., 2021), this setting was deemed appropriate for the fully tethered swimming condition. In the fully tethered swimming trials, the first 2-3 seconds contained slight forward movement, presumably due to the large momentum from push-off. Therefore, this initial phase was excluded from the analysis. After trimming the data, the mean force value (FT) of the three fully tethered swimming outcomes was used for further analysis. L0 was estimated using the load-velocity profiling method, as described in Gonjo et al. (2021). The normality of data was checked using the Shapiro-Wilk test and confirmed for both L0 and FT. Therefore, the person's correlation coefficient was used to assess the relationship between the two variables with alpha = 0.05.

RESULTS: There was a significant correlation between L0 and FT (r=0.727, p=0.005). The inter-participant mean of FT was 155.77±27.49 N. When normalising this variable with the body mass, the inter-participant mean value was 1.99±0.19 N/kg, which was close to male competitive swimmers' data presented in a previous study which reported FT of 133.2±16.8 N with 70.4±6.3 kg body mass (Loturco et al., 2016).

CONCLUSION: In conclusion, L0 and FT are strongly related, which suggests that L0 is an indicator of a swimmer's ability to generate the propulsive force.

OP-AP20 Sleep

SLEEP HABITS OF YOUNG FOOTBALL PLAYERS: CAN THE WEEKEND OFF HELP CATCH UP FROM SLEEP DEBT?

BARREIRA, J., BRITO, J.2, NAKAMURA, F.1, FIGUEIREDO, P.3,4,2

1: CIDESD, UNIVERSITY OF MAIA, PORTUGAL 2: PORTUGAL FOOTBALL SCHOOL-FPF, PORTUGAL 3: UNITED ARAB EMIRATES UNIVERSITY, UAE 4: CIDESD, VILA REAL, PORTUGAL

INTRODUCTION: Sleep is essential for the health and well-being of all individuals. However, the younger population appears more vulnerable to short sleep durations, most likely due to a combination of biological, psychosocial, and societal pressures that come together and compete with one another affecting sleep [1]. Thus, it is common for teenagers to adjust their sleep schedules during the weekends to "catch up" on their sleep debt from weekdays [2, 3]; however, this might not be possible for young football players since they play official matches on the weekends during the competitive period.

METHODS: Twenty-three highly trained young football players (mean ± SD; age: 17.3 ± 0.6 yrs) from the same U19 team were recruited. Sleep was objectively monitored using actigraphy devices for eight weeks, comprising two types of microcycles: normal (i.e., with an official match on the weekend) and off (i.e., with a weekend off, without matches). Linear mixed models were used to analyze the differences in sleep variables between microcycle type (normal vs. off) and night-type (weekday vs. weekend). Significance was set at $p<0.05$. Effect sizes from post-hoc analysis were calculated using Cohen's d (d).

RESULTS: Throughout the eight weeks, average total time in bed (TIB) was 505.1 ± 65.3 min, total sleep time (TST) 399.0 ± 63.7 min, sleep efficiency 78.9 ± 7.9%, and wake after sleep onset 98.3 ± 41.4 min. Average bedtime was at 23:48 ±

01:03, and wake-up at 08:18 ± 01:24. Eighteen (80%) players slept less than 7h on weekdays, independent of microcycle type. Sixteen (70%) players slept less than 7h on regular weekends, and seven (30%) players on off weekends.

A significant (p<.05) main effect of the microcycle type, night of the week, and an interaction between both were verified for TIB, TST, bedtime, and wake-up time, indicating that weekend sleep adjustments were dependent of playing a match or not. Weekends off presented higher TIB (+35.8 min, p=.0001, d= .32) and TST (+33.6 min, p<0.0001, d=.33), and later bedtimes and wake-up times (+48 min, p<.0001, d=.43; and +01.06h, p<.0001, d=.60; respectively) compared with regular weekends with a match. Similar TIB and TST were observed between weekday and weekend-nights of normal microcycles.

CONCLUSION: Young football players adopted a compensatory sleep behavior on weekends without competitive matches. Despite this behavior, it is questionable whether the observed increase in TST is sufficient to compensate weekdays sleep debt. Also, considering the importance of maintaining a regular sleep schedule, it is arguable whether this behavior is healthy, given the regular changes on sleep schedules between weekday and weekend nights.

DO TRAINING LOADS OR MICROCYCLE DAYS INFLUENCE SLEEP PATTERNS? AN OBSERVATIONAL STUDY WITH YOUNG MALE FOOTBALL PLAYERS

CUNHA, L., BRITO, J.2, LASTELLA, M.3, FIGUEIREDO, P.4,5

1.CIDESD, UNIVERSITY OF MAIA, PORTUGAL; 2.PORTUGAL FOOTBALL SCHOOL, FPF, PORTUGAL; 3.CENTRAL QUEENSLAND UNIVERSITY, AUSTRALIA ; 4.UNITED ARAB EMIRATES UNIVERSITY, UAE; 5.CIDESD, VILA REAL, PORTUGAL

INTRODUCTION: Training loads and daily schedules are referred to as relevant sports factors that influence athletes sleep [1]. Yet, data examining training loads or daily schedules in young football players is scarce. Therefore, this study aimed to describe the sleep habits and needs of young football players, analyzing the differences between microcycle days and the influence of training/matches workloads.

METHODS: The study included 60 young male football players with a mean age of 16.3 ± 1.4 years old. For two weeks, the players wore a 3-axial accelerometer during sleep, filled out sleep diaries, and answered the question "how many hours of sleep do you need to feel rested?". A difference of 1h or more between sleep needs and sleep duration was considered sleep deficit [2]. Training/matches external workloads were monitored using 10-hz GPS devices. Linear mixed models were used to examine the differences between sleep duration and sleep efficiency between training (TD), match (MD), and rest days (RD). Within-subjects correlations were tested between sleep duration, sleep efficiency and training/matches external workload metrics (total distance, high-speed running distance, and sprinting distance).

RESULTS: : On average, players obtained 8.1 ± 1.5 hours of sleep duration, had a sleep efficiency of 83 ± 7% and reported needing 8.8 ± 0.9 hours of sleep. Twenty-seven athletes (45%) slept less than 8 hours per night, thirty-six (60%) had a sleep efficiency below 85%, and fifteen (30%) had a sleep deficit. Regarding the differences on sleep between microcycle days, players slept 8.0 ± 1.5 hours and had 83 ± 7% sleep efficiency on training days, 7.6 ± 1.5 hours and 83 ± 9% on match days, and 8.5 ± 1.3 hours and 84 ± 6% on rest days. There was a trivial main effect for microcycle days on sleep duration (F=3.1, p=0.04, ηp2= 0.009), but not on sleep efficiency (p=0.78). No associations were found between sleep duration/efficiency and external workload metrics (p>0.05).

CONCLUSION: The results of this study revealed that one-third of the players presented a sleep deficit, and two-thirds had a sleep efficiency below 85%. It appears there were trivial to no differences between the microcycle days on sleep duration and sleep efficiency. Also, external training/match workloads throughout the microcycle were unrelated to sleep duration and efficiency

HIGH LEVELS OF POST-SLEEP FATIGUE AND POOR SLEEP QUALITY ARE ASSOCIATED WITH INSUFFICIENT SLEEP IN FOOTBALL PLAYERS

FIGUEIREDO, P.1,2,3, CUNHA, L.2, BARREIRA, J.2, NAKAMURA, F.Y.2, LASTELLA, M.4, BRITO, J.3, MARQUES, E.A.5,2

1: UNITED ARAB EMIRATES UNIVERSITY, UAE, 2: CIDESD, PORTUGAL, 3: PORTUGAL FOOTBALL SCHOOL-FPF, PORTUGAL, 4: CENTRAL QUEENSLAND UNIVERSITY, AUSTRALIA, 5: UNIVERSITY OF KALBA, UAE

INTRODUCTION: Sleep is recognised as an essential component of athletic performance and recovery. Research on the sleep requirements of football players is scarce (1,2), revealing that athletes typically obtain less sleep than their self-

assessed needs. This highlights a need to research how daily objective sleep data, factors related to training demands and sleep patterns impact sleep. This study aimed to compare the self-assessed sleep needs of football players with daily objective measures of sleep duration and to explore the relationship between daily fatigue, external workloads and sleep habits with sleep insufficiency.

METHODS: For 2 weeks, 72 football players (19 females; 19.5 ± 4.4 years old) wore an accelerometer to measure sleep duration and efficiency and reported daily pre- and post-sleep perceived fatigue and sleep quality using a Likert scale (1: very, very low/poor; to 7: very, very high/good). Total distance during training/matches (external workloads) was measured using GPS devices. The players answered the question, "how many hours of sleep do you need to feel rested?". A daily sleep index was calculated by subtracting sleep duration from individual self-assessed sleep needs. A difference of 1 hour or more indicated insufficient sleep (1). Sleep quality index was measured using the Pittsburgh Sleep Quality Index (PSQI), daytime sleepiness with the Epworth Sleepiness Score, and chronotype with the Morningness-Eveningness Questionnaire. Differences between sleep needs and sleep duration were analyzed using a linear mixed model. A generalized mixed-effects regression tree was applied using the daily sleep index (sufficient sleep vs insufficient sleep) as the outcome variable.

RESULTS: Players reported an average subjective sleep need of 8.4 (min-max: 6-11) hours and slept an average sleep duration of 8.2 (min-max: 5.5-10.3) hours ($p < 0.001$). The prevalence of insufficient sleep was 25% (157 out of 619 recorded nights), with 48 (67%) of players having at least one night of insufficient sleep. The generalized mixed-effects regression tree revealed daily post-sleep fatigue and sleep quality (PSQI) as the significant factors associated with daily sleep insufficiency. Also, those with high to very, very high daily post-sleep fatigue (> 5) had a higher prevalence of insufficient sleep than those with average to very, very low daily post-sleep fatigue (≤ 5). Among those with average to very, very low post-sleep fatigue (≤ 5), having poor sleep quality (PSQI >5) was associated with a higher prevalence of insufficient sleep.

CONCLUSION: Daily post-sleep fatigue and sleep quality (PSQI) were selected as explanatory variables of daily sleep insufficiency. These results highlight that monitoring post-sleep fatigue can be used to track athletes obtaining insufficient sleep, which can negatively affect performance, recovery, and health.

ENHANCING SLEEP QUALITY IN PROFESSIONAL RUGBY PLAYERS: ASSESSMENT AND INTERVENTION

GOLDBERG, M., BOUTIN, A., COHN, J., MICHEL, V., STAUFFER, E., DEBARNOT, U.
UNIVERSITÉ LYON 1

INTRODUCTION: Sleep is a crucial factor in recovery and must be integrated into athletes training plans for optimal performance and well-being1. Although professional athletes are advised to sleep for a minimum of 8 hours1, many experience shorter sleep durations or exhibit poor sleep efficiency, especially after matches or hard training cycles2,3. Recent sleep tracking observations in athletes suggest that sleep quality is altered, yet this emerging field of research requires comprehensive assessments, including objective and subjective sleep outputs. To improve sleep quality, sleep interventions have been recently tested with various modalities, including among others, sleep hygiene education and sleep strategies. Importantly, combinations of sleep interventions have been shown to improve sleep quality in young elite athletes 3,4. Therefore, across match weeks, this ecological study aimed to identify good and poor sleepers within a professional male rugby team, using both objective and subjective assessments, and to evaluate the effects of sleep interventions, including sleep hygiene education and strategies.

METHODS: Forty-three male professional rugby players from national French rugby union were evaluated during two tracking and intervention match weeks using objective and subjective assessments (i.e., actimeter and Hooper questionnaire). During the first tracking week, we assessed the wake-sleep cycle of athletes who maintained their daily habits. Then, two sleep experts reported the results from the tracking phase in a group setting context and offered an educational session on sleep hygiene (30 min). Sleep experts further taught them how to practice relaxation strategies (15 min), which they could implement as needed during the post-intervention week.

RESULTS: Our findings revealed that 65 % of players were considered bad sleepers. Subjective sleep quality improved between the tracking and the intervention weeks ($p = 0.002$, $\eta 2 = 0.22$). A significant effect of the sleep hygiene intervention was also found on bedtime ($p = 0.005$, $\eta 2 = 0.19$), which occurred earlier during the intervention week (23:25 ± 00:38 vs. 23:43 ± 00:44 during tracking). A trend towards significant increases in objective (actimetric) sleep quantity was also observed (421.3 min during tracking week vs. 433.4 min during intervention week; $p = 0.07$, $\eta 2 = 0.08$).

CONCLUSION: The first main finding revealed that a majority of professional rugby players did not sleep sufficiently, which extends previously reported results from different sports1,2,3,4. The second main finding demonstrated that sleep interventions improved sleep quality and quantity. This study offers a simple and accessible method for evaluating sleep status in team sports athletes, while providing feedback to optimize and enhance sleep quality and quantity.

POSITIVE SLEEP OUTCOMES ASSOCIATED WITH INCREASED MORNING AND DAYTIME LIGHT EXPOSURE IN ELITE TEAM SPORT ATHLETES

STEVENSON, S., SUPPIAH, H., RUDDY, J., MURPHY, S., DRILLER, M.
LA TROBE UNIVERSITY

INTRODUCTION: Light exposure techniques have been recommended to combat sleep issues caused by disruption to circadian regularity in the athletic population, although no studies have measured light exposure and sleep outcomes in an elite athlete setting.

METHODS: A total of 17 professional male Australian Football athletes (age ± SD: 22 ± 3 years) wore a wrist actigraph to measure sleep parameters, and a wearable light sensor to measure melanopic equivalent daylight illuminance (mEDI, in lux) for 14 days. Participants completed three sleep questionnaires at the end of the data collection period and completed wellbeing surveys 6 times. The Sleep Regularity Index (SRI) for each player was also calculated from actigraphy data. Light exposure data were organised into three different timeframes; morning (wake time + 2 hours), daytime (end of morning to 6 pm), and evening (2 hours leading up to bedtime) for analysis.

RESULTS: Higher morning light was associated with significantly ($p < 0.01$) greater total sleep time ($r = 0.26$). Higher daytime light exposure was associated with higher subjective sleep quality ($r = 0.48$, $p < 0.05$). Higher evening light exposure was associated with higher ASSQ global scores ($r = 0.52$, $p < 0.05$), and lower sleep efficiency ($r = -0.25$, $p < 0.01$). There were no other significant correlations between light exposure and sleep or wellbeing measures ($p > 0.05$).

CONCLUSION: Higher morning and daylight exposure levels were associated with various positive objective and subjective sleep measures in professional team sport athletes, supporting the need for education on optimising light exposure to improve circadian function, sleep, and health.

CARDIORESPIRATORY AND NEUROMUSCULAR RESPONSES TO SINGLE-LEG ECCENTRIC CYCLING: EFFECT OF PEDAL CADENCE AND BLOOD FLOW RESTRICTION

DUFOUR, S.P.1, MAVROPALIAS, G.2,3, SCOTT, B.R.3, HASELER, L.4, NOSAKA, K.3
1 UNIV STRASBOURG, FRANCE 2 EDITH COWAN UNIV, AUSTRALIA 3 MURDOCH UNIV, AUSTRALIA 4 CURTIN UNIV, AUSTRALIA

INTRODUCTION: Eccentric (ECC) cycling allows greater mechanical load to be achieved despite lower metabolic demand [1] and induces different acute cardiorespiratory and neuromuscular responses than those observed during conventional concentric (CON) cycling [2-3]. The present study aimed to determine how pedal cadence and blood flow restriction (BFR) to the exercising limb affect acute cardiorespiratory, vascular and neuromuscular responses to ECC cycling.

METHODS: Healthy males (n=10, 38±10y, BMI 24.0±2.5) completed 4 sessions over 4-wk. The first two sessions were used to familiarize the participants to procedures including single leg (SL) ECC cycling, maximal voluntary knee extensor isometric strength (MVC) and microvascular function tests (MVF) based on vastus lateralis (VL) oxygenation response to 5-min arterial occlusion/reperfusion. In addition, SL-CON cycling sprint power for 10-s at 20- and 60-rpm were measured. The following two visits consisted of 15 bouts of 40-s SL-ECC cycling at 25% SL-CON sprint power, with 20-s passive cycling recovery. One leg cycled with BFR (60% of arterial occlusion pressure) while the other cycled without (non-BFR). Cardiorespiratory function (indirect calorimetry and telemetry), VL oxygenation (near infra-red spectroscopy) and electromyographic activity (EMG) were continuously recorded. Blood lactate (BL), MVC and MVF were assessed before and after exercise. Two-way repeated measures ANOVAs were performed to test for cadence and BFR effects on the measures. All data are expressed as mean ± SD and a significant level was set at $p<0.05$.

RESULTS: Mean power output was higher ($p<0.001$) at 60- (133±23W) than 20-rpm (57±11W) without difference between BFR and non-BFR conditions. Oxygen uptake (+58%), heart rate (HR, +15%), pulmonary ventilation (+28%) and breathing rate (BR, +25%) were greater during exercise at 60-rpm than 20-rpm ($p<0.05$). VE (+20%) and BR (+13%) were higher ($p<0.05$) in the BFR than non-BFR condition, while HR tended to be higher (+6%, $p=0.066$) with BFR than non-BFR. VL oxygenation was 6% lower at 60- than 20-rpm and also reduced by 16% in BFR compared to non-BFR condition (cadence effect $p<0.01$, BFR effect $p<0.001$). Post-exercise BL was not significantly altered by cadence but was 38% higher ($p<0.05$) in the BFR than non-BFR condition. There was no significant cadence nor BFR effects on EMG activity, MVC and MVF tests.

CONCLUSION: These data suggest greater acute cardiorespiratory and muscle metabolic challenges when ECC cycling is performed at faster pedal cadence with BFR. Therefore, combining faster pedal cadence and BFR might be a useful strategy to enhance cardiorespiratory and muscle metabolic training stimuli for future chronic studies exploring the functional benefits of ECC cycling in clinical and athletic populations.

RELATIONSHIP BETWEEN HEART RATE KINETICS IN THE MODERATE INTENSITY DOMAIN OF EXERCISE WITH RESTING HEART RATE VARIABILITY IN NORMAL WEIGHT PERSONS AND PERSONS WITH GRADE I OBESITY

ACEITUNO PINTO, H., CANO-CAPPELLACCI, M., OPAZO-DÍAZ, E., YUMHA, M.J., AMADOR, P.
UNIVERSIDAD DE CHILE

INTRODUCTION: Recently, it has been reported in young, trained males and males with obesity that in the moderate intensity domain of exercise, heart rate (HR) kinetics exhibit a slow component, distinct from oxygen uptake, which reaches a steady state at intensities below ventilatory threshold 1 (VT1). The functional significance of the slow component in at moderate intensity is unclear. The autonomous nervous system (ANS) is known to be the principal modulator of HR during exercise. Therefore, the aim of this study is to establish the relationship between HR variability, representing the ANS, and the HR kinetics in moderate intensity domain in normal weight persons and persons with grade 1 obesity.

METHODS: Sixteen persons with grade I obesity (OB) of 27 ± 4 years old and sixteen age-matched normal weight persons (NW) were recruited. All volunteers visited the laboratory on two non-consecutive days. On the first day, resting HR variability was measured, and an incremental test was conducted to determine VT1. HR variability assessment involved calculation of low frequency (LF), very low frequency (VLF) and high frequency (HF) power and the ratio LF/HF. On second day, subjects performed three transitions from unloaded cycling to 70% of the load associated with VT1. HR was measured during each transition. HR kinetics were determined for each participant following the procedure described by Zuccarelli et al. (2018). One of three possible models: mono-exponential, biexponential, and exponential+linear) were fitted to the HR data. The frequency of each model in each group was compared using chi-squared analysis. Comparisons between groups were made using the Mann-Whitney test, and Spearmans test was used to establish correlations between variables. Statistical significance for all tests was set at $p \leq 0.05$.

Zuccarelli, L. et al. (2018). Comparison between Slow Components of HR and V&O2 Kinetics. Medicine & Science in Sports & Exercise, 50(8), 1649–1

RESULTS: In the OB group, the frequency of HR kinetics with mono-exponential, biexponential, and exponential+linear models was 2, 10, and 4, respectively, whereas in NW group was 2, 12, and 2, respectively, with no significant differences in frequency between groups ($p = 0.65$). Significant differences between NW and OB groups were found in baseline HR ($p = 0.018$) and time delay ($p = 0.001$). Significant correlations were observed in the OB group between baseline heart rate and LF (Rho = -0.51) and LF/HF (Rho = -0.46). In the other hand, in the NW group, significant correlations were observed between fundamental HR and LF (Rho = 0.42) and VLF (Rho = 0.47).

CONCLUSION: NW and OB persons exhibit similar HR responses to constant load moderate exercise, and not all subjects exhibit the HR slow component. Parameters of heart rate variability are related differently with heart rate kinetics parameters in OB and NW groups. Further studies could focus on identifying factors that determine the type of heart rate response to moderate exercise intensity.

VITAMIN D SUFFICIENCY IS ASSOCIATED WITH BETTER VASCULAR IMPROVEMENTS AFTER HIGH INTENSITY INTERVAL TRAINING IN HEALTHY ADULT MALES

CHEN, L.Y., WANG, C.W., CHEN, L.A., HE, C.S.
NATIONAL CHUNG CHENG UNIVERSITY

INTRODUCTION: Cardiovascular disease (CVD) stands as a primary contributor to global mortality. Arterial stiffness has been established as an independent risk factor for both CVD and mortality. Peripheral pulse wave velocity (pPWV) serves as an indicator of arterial stiffness and represents a significant risk factor for CVD. Previous research has demonstrated an association between vitamin D deficiency and arterial stiffness (1). Prior study has indicated that high intensity interval training (HIIT) can effectively improve arterial stiffness (2). However, the impact of HIIT training on individuals with different levels of vitamin D remains unclear. The primary objective of this study was to compare different vitamin D status on vascular function following two weeks HIIT in healthy adults.

METHODS: Forty-three adult males were divided into the 25(OH)D sufficient group (n=29, vitamin D≧50 nmol/L) and deficient group (n=14, vitamin D <50 nmol/L). The maximal graded exercise was performed using on upright bikes an incremental cycling test to exhaustion. The training intervention consisted of two weeks of high intensity cycling training, five days/week, consisting of 10 × 1 min bouts at 90% of HRpeak with 1 min rests. The pPWV and blood pressure (BP) were measured at baseline, on the mid-training, and post-training. The pPWV and BP variables were subjected to a two-way analysis of variance (ANOVA). Subsequent to identifying significant interaction and main effects, post hoc comparisons were conducted using t-test analysis. Changes in mean arterial pressure (MAP) and pPWV during HIIT were assessed using the area under the curve (AUC) method based on the trapezoidal rule, followed by a t-test on AUC values between groups. The accepted level of significance was set at $p < 0.05$.

RESULTS: Baseline characteristics showed no significant differences, except for vitamin D concentrations. Both the vitamin D sufficient and deficient groups exhibited a significant reduction in pPWV ($p < 0.05$). The vitamin D sufficient group showed a significant lower systolic BP at post-HIIT compared with deficient group (116.17 ± 11.39 vs 120.25 ± 11.22 mmHg). The sufficient group demonstrated a significant reduction in systolic BP at post-HIIT compared to baseline (122.59 ± 13.65 vs 116.17 ± 11.39 mmHg). In addition, AUC for both pPWV and MAP in vitamin D sufficient group was significantly smaller

than deficient group ($p < 0.05$). There were no significant changes in systolic BP between the baseline and post-HIIT training in the vitamin D deficient group ($p > 0.05$).

CONCLUSION: In this study, we found that adults with 25(OH)D sufficiency have a better vascular function improvement after two weeks of HIIT. People with sufficient vitamin D status may experience better vascular vasodilation and blood pressure reduction during each high-intensity training session.

SKELETAL MUSCLE SIGNATURE OF ELITE MASTER ENDURANCE RUNNER WITH THALASSEMIA – A CASE STUDY

STRELECKY, M., SEDLIAK, M., BERISHA, G., ORESKÁ, L., BUZGO, G., CERNÁCKOVÁ, A., OKULIAROVA, M., ZEMAN, M., KERN, H., ZAMPIERI, S., PIETRANGELO, L., PROTASI, F.

FACULTY OF PHYSICAL EDUCATION AND SPORTS COMENIUS UNIVERSITY

INTRODUCTION: Thalassemia is a type of inherited hemoglobinopathy resulting in reduced ability to produce haemoglobin. Depending on a type of thalassemia, endurance performance may be negatively affected but there is lack of evidence in master athletes. We had a unique opportunity to examine not only performance and blood parameters but also skeletal muscle characteristics of an elite male master marathon runner who placed second at the World championship in the age category 75-79 years and won all the World Marathon Majors between 2013 and 2019.

METHODS: A 79-year-old Caucasian male (body height 168.2 cm, body mass 59.5 kg, BMI 21 kg/m2) with hereditary form β-thalassemia voluntarily participated in this study. The data were collected throughout the 3 weeks. During the first week, maximal isometric voluntary contraction (MVC) of the knee extensors and incremental laboratory exercise test to on a bicycle ergometer for VO2max were performed. During the second week, the subject was instructed to maintain his habitual daily activities. During the third week on Tuesday, the subject underwent a blood sampling procedure and muscle biopsy for histological analyses. All data were compared to earlier results from our laboratory.

RESULTS: As expected, blood count showed abnormalities in hemoglobin values (106 g/l, reference range (r.r.) 135-172 g/l), haematocrit (0.33% r.r. 0.42-0.52%), MCV (64.2 fl, r.r. 84-98) and MCH (20.7 pg r.r. 28-34), Serum iron concentration, its binding capacity, ferritin, and transferrin were within the normal range. Histology - the individual´s mean myofiber diameter values (58.60 ± 13.92 μm) very similar to that observed in young adult, and higher in comparison to that observed in aged-matched sedentary elderlies. The two type-groupings refer to reinnervation events and circulating levels of C-terminal agrin fragment as a biomarker of neuromuscular junction destabilization was lower than in aged matched sedentary elderlies (5623 pg/ml vs 6350,7 pg/ml). Electron microscopy - the high mitochondria number (more than doubled if compared to sedentary seniors of the same age) was not accompanied by a parallel marked increase in their volume and a small average size of these organelles is reported. Taken together these factors suggests that possibly mitochondria are undergoing active fission processes. In bilateral knee extension and flexion, the MVC values were 138.2 Nm and 34.91 Nm/kg, respectively. The predicted VO2max value was 44.3 ml/kg/min.

CONCLUSION: Despite the thalassemia and impaired parameters of blood count, the performance and muscle tissue quantitative and qualitative measures were well preserved in the elite master marathon runner. Moreover, analysed muscle tissue was in several aspects more similar to young men than to the subjects' age-matched sedentary counterparts.

The study was supported by the Slovak Research and Development Agency (grant no. APVV-21-0164).

EXERCISE MODE INFLUENCES THE ACUTE EXPRESSION OF GILZ WITHIN SKELETAL MUSCLE

PAUL, S., DONATH, L., HOPPSTAEDTER, J., HECKSTEDEN, A.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: The glucocorticoid induced leucin zipper (GILZ) is a protein originally described as an anti-inflammatory regulator of gene expression in lymphatic tissue (1). Since then, expression of GILZ has been identified in a variety of tissues. This includes skeletal muscle where it has anti-myogenic effects and mediates the well-known muscle-related side effects of glucocorticoids but also of statins (1). Interestingly, recent evidence suggests that GILZ expression is also regulated by physical exercise with muscular, as opposed to cardiocirculatory strain, being the decisive factor (2). To verify these seminal findings, we performed a retrospective analysis of datasets from acute exercise trials published in Gene Expression Omnibus (GEO).

METHODS: We conducted a systematic search of the GEO repository for gene expression studies reporting the acute effects of either endurance, conventional resistance, or eccentric resistance exercise. Gene expressional data was required to be quantified either via micro array or high throughput sequencing techniques. Only studies on healthy adults were eligible. Additionally, muscle biopsies must have been obtained acutely (3-6h) post exercise. Within-trial robust scaling of raw data was used to account for variation between trials. ANOVA and post hoc testing were used to compare changes in GILZ expression from pre- to post-exercise between groups.

RESULTS: A total of 14 studies and 258 subjects (213 male; 45 female) could be included into the analysis. Activity level ranged from sedentary to endurance trained, and the age of examined individuals ranged from 18 to 90 years (35.2 ± 2.8 [mean ± SD]). Eccentric exercise resulted in the greatest downregulation of GILZ (- 0.56 ± 0.92 [AU]), closely followed by

resistance exercise (- 0.46 ± 1.07 [AU]), and little change in GILZ expression was observed with endurance exercise (- 0.1 ± 0.93 [AU]).

CONCLUSION: Our results support the hypotheses that mechanical strain is a key mediator of training induced changes in GILZ expression. It is noteworthy that this result has been obtained despite the substantial differences in age, level of habitual exercise, and exercise dose across studies.

OP-SH02 Psychology

A QUALITATIVE STUDY OF RETIRED FEMALE ATHLETES LIVED EXPERIENCES PERTAINING TO COACHING PRACTICES AND THEIR RECOMMENDATIONS FOR FEMALE-SPECIFIC COACH EDUCATION PROGRAMS

AUSLAND, Å., TORSTVEIT, M.K., IVARSSON, A., KNIGHT, C.J., SOLSTAD, B.E.

UNIVERSITY OF AGDER

Introduction: Sports coaching is a pivotal factor in the development and success of athletes, yet a noticeable knowledge gap in coach education programs specifically tailored for coaching of female athletes still exists. This qualitative study explored the lived experiences of retired elite female athletes to inform the development of female-specific coach education programs. By delving into the perspectives of these elite athletes, the purpose of the present study was to identify areas for improvement in coaching practices and content for future coach education programs.

Methods: In-depth interviews were conducted with retired elite female athletes (n=8) representing diverse sporting backgrounds, including both team and individual sports. All participants had represented Norway at the elite level in their sports, respectively, including the Olympic Games and World Championships. These interviews explored athletes lived experiences, preferences, and recommendations pertaining to coaching practices and the needs of female-specific coach education programs. Reflexive thematic analysis was used to analyse the collected data.

Results: The interviews revealed several recurring themes concerning coaching of female athletes. Notably, athletes emphasized the importance of coaches understanding of the biological, psychological, and social (biopsychosocial) needs of female athletes. Specifically, biological aspects of injuries and the menstrual cycle was underpinned by their own experiences as well as experiences of peer athletes that did not make it to the elite level. Effective communication also emerged as a key aspect of coaching, with athletes highlighting the significance of coaches who actively listened and responded to their needs. Furthermore, there was a consensus among the athletes regarding the necessity for coach education programs to be tailored specifically to the requirements of coaching female athletes. The interviews also provided more nuanced insights into the attributes of exemplary coaches as well as areas where coaching practices could be further improved.

Discussion: The findings underscore the critical need for coach education programs that are addressing the distinct coaching needs of female athletes. By incorporating insights from retired elite athletes, such as the importance of understanding females' biopsychosocial needs, future coach education programs can better prepare coaches to support and empower this overlooked group of athletes. Addressing these key areas for improvement will not only benefit individual coaches, but also contribute to the overall athletic participation, development, and performances of female athletes in sports.

Conclusion:These lived experiences of retired female athletes provide valuable insights for establishing the needs of coaches who are coaching female athletes, thereby providing important steps toward developing a biopsychosocial coach education program for improved coaching of female athletes.

SHELTER ME FROM THE STORM: AN ATTACHMENT PERSPECTIVE ON INDIVIDUALS' RELATIONSHIP WITH THEIR SPORTING ACTIVITIES.

WILLEGERS, M., WOODMAN, T.

BANGOR UNIVERSITY

Objective: We aimed to develop and validate new attachment scales to explore the degree to which individuals use their attachment to sporting activities to compensate for insecure attachments in close interpersonal relationships – the Compensatory Hypothesis.

Design: At present, there is no scale that captures the support that human-nonhuman attachments provide according to Bowlbys notion of an attachment and exploratory behavioural system. In Study 1 we developed such a scale to test the Compensatory Hypothesis in Study 2.

Methods: We sampled 286 participants through online surveys (Facebook, Instagram). In Study 1, we used Bayesian Structural Equation Modelling in Mplus to analyse the model fit of the four-factor Relationship Attachment Support Scale (RASS; safe haven, secure base, proximity maintenance, and separation distress) and the six-factor Relationship Exploratory Support Scale (RESS; security in exploration, emotion regulation, personal reflection, development, self-expression, and self-esteem). In Study 2, we used PROCESS to explore the degree to which individuals use their attachment to sporting activities to compensate for insecure attachments in interpersonal relationships – the Compensatory Hypothesis.

Results: We found excellent model fit (ppp >.05, factor-loading >.4) and psychometric properties for the RASS and RESS across both activity and interpersonal relationships. In Study 2, we used these scales to test the Compensatory Hypothesis. Moderation analysis revealed that the emotion regulation transfer benefits of individuals activity attachments significantly (p <.05, R2 = .03 - .1) reduced the negative relationship between insecure interpersonal attachment and wellbeing.

Conclusion: These results provide valuable insight into the emotion regulation role of activity attachments for individuals who suffer from insecure interpersonal attachments and the broader application of the RASS and RESS.

A MULTI-STAGED INVESTIGATION OF FEARS OF COMPASSION IN COMPETITIVE SPORTS

MICHALCZYK, M., ZHANG, S., MCEWAN, K., SHEFFIELD, D.

UNIVERSITY OF DERBY

Background: To date, research has demonstrated the wide benefits of compassionate minds in sports, such as adaptive psychophysiological responses to stress, greater mental well-being, and superior coping under challenging performance scenarios. However, barriers still exist when incorporating compassion in competitive sports (e.g. fear of losing personal standards), which requires further research attention. As such, we aimed to gain an in-depth understanding of fears of compassion in athletes and its manifestations in sports by adopting a multi-staged investigation consisting of focus groups and 1-1 interviews.

Method: We recruited 18 competitive athletes (Mean age = 23.3, SD = 2,8; 44.4 % of male) and assigned them randomly to one of the three initial focus groups (i.e., the exploratory stage). We then conducted 1-1 semi-structured interviews (i.e., the confirmatory stage) with each participant. Reflexive thematic analysis (RTA) was performed to understand the fears of compassion in sports.

Results: We identified 3 main themes with 2 subthemes for each main theme. Theme 1 unveiled the context-specific nature of fears of self-compassion in competitive sports, with two emerging subthemes namely compassion during sports performance and compassion as an 'aftermath'. Theme 2 reflected the social dynamics of fears of compassion, with two emerging subthemes namely fear of giving compassion and fear of receiving compassion. Theme 3 uncovered the impact of sports cultures on fears of compassion, with two emerging subthemes namely team sport culture and individual sport culture.

Discussion: Fears of self-compassion in competitive sports appeared to be context-specific. Athletes tended not to use compassion during performance but would likely adopt it afterwards as there is 'no time' to think about adopting a self-compassionate mind during performance. Fears of giving compassion to other athletes appeared to be dependent on the extent to which they know the person(s) and their skill level. More specifically, athletes said they are keen to offer compassion to athletes they know well, however are fearful of giving compassion to athletes with a 'higher rank' than them. Similarly, the extent to which one feared receiving compassion from others appeared to depend on the 'source' or 'origin' of compassion. That is, athletes reported a greater level of acceptance and lower level of fear when they received compassion from coaches compared to their teammates. Lastly, fears of compassion were perceived differently in individual vs team sports due to the varied challenges and cultures that offer unique fears.

Conclusion: Fears of compassion in competitive sports are context-specific and rooted in the social dynamic in sports and performance settings. Perhaps a state fears of compassion in sports scale is needed for a more comprehensive assessment of such fears to inform assessment, monitoring, and evaluation processes when implementing compassion in sports.

EFFECTIVENESS OF MOTIVATIONAL STRATEGIES IN A 12-WEEK SUPERVISED EXERCISE PROGRAM ON PHYSICAL AND WELL-BEING OUTCOMES IN OLDER ADULTS: PRELIMINARY FINDINGS FROM THE PRO-TRAINING PROJECT

INTRODUCTION: Integrating motivational strategies within exercise programs may enhance physical and well-being outcomes in older adults (1), although their actual effectiveness remains unclear. This study aimed to analyze the effect of motivational strategies during a supervised exercise program on physical and well-being outcomes in individuals aged 60-75 years.

METHODS: This work is part of the PRO-Training project (NCT05619250). A sample of 72 participants (69.1 ± 4.2 years old) was randomly allocated into 3 groups: 1-Control, 2-Supervised exercise without motivational intervention (SUP), 3- Supervised exercise with motivational intervention (SUP+). Over 12 weeks, supervised groups engaged in a multicomponent exercise program 3 times per week, while the control group maintained their usual lifestyle. Motivational intervention was based on the self-determination theory, including strategies such as phone calls, interactive workshops, motivational messages, informative infographics, and videos. Physical outcomes included upper-body (30-seconds biceps curl test) and lower-body (5-repetition [5-STS] and 30-second [30-STS] sit-to-stand tests) strength. Well-being involved health-related quality of life assessed using the visual analog scale (EQ-VAS). Outcomes were assessed at baseline and after 12 weeks. Statistical analyses included multivariate analysis of variance and Bonferroni post-hoc tests for parametric variables, and Kruskal-Wallis for nonparametric variables. Results are change from baseline, presented as mean ± SD change.

RESULTS: Significant benefits were observed for SUP+ (2.6 ± 1.6 repetitions, p=0.013) and SUP (1.9 ± 2.6 repetitions, p=0.013) compared to the control group (-0.4 ± 2.5 repetitions) in the biceps curl test. Although no significant differences were found between SUP+ and SUP for any outcome, additional benefits were observed for SUP+ -but not SUP- over the control group for 5-STS (-1.6 ± 1.2 vs. -0.6 ± 0.7 seconds, respectively, p=0.05), 30-STS (3.4 ± 3.1 vs. 1.4 ± 2.4 repetitions, respectively, p=0.021), and EQ-VAS (6.6 ± 13.3 vs. -4.1 ± 16.3 scores, respectively, p=0.035).

CONCLUSION: Motivational strategies appear to maximize the benefits on health-related quality of life and muscle strength during a 12-week supervised training program in older adults. However, further research with larger sample sizes is warranted to confirm these findings.

A COMPARATIVE STUDY OF GOAL ORIENTATIONS, SELF-DETERMINED MOTIVATION, NEEDS SATISFACTION, AND COACH-ATHLETE RELATIONSHIP QUALITY BETWEEN ADOLESCENT ATHLETES WHO DISCONTINUED PARTICIPATION AND THOSE WH

LIU, Z., NEVILLE, R.D.

UNIVERSITY COLLEGE DUBLIN

Background. Numerous systematic reviews have reported a link between adolescent athletes' intentions to continue or drop out of competitive sports and factors such as goal orientations, levels of self-determined motivation, satisfaction of basic needs, and their relationship with their coach. However, there remains limited evidence regarding the differences in means for these crucial psychosocial factors between adolescent athletes who have discontinued participation in competitive sports and those who remain active, thus constituting the primary aim of this study.

Methods. A cross-sectional research design was applied. 78 athletes (mean age 22.6 ± 0.8, 42% female) were recruited from an international Rugby Football Union database in Ireland and responded to an online questionnaire administered through Microsoft Forms. The measures employed in this study have demonstrated acceptable reliability and validity in previously published investigations. Data were analysed using multivariate analysis of variance in SPSS Version 27. Differences between groups were standardised to a Cohen's d value and the resulting effect sizes were evaluated using the following scale: <0.2, slight; 0.2 to <0.6, small; 0.6 to <1.2, moderate; ≥1.2, large. The level of evidence for each effect was assessed by interpreting the uncertainty and range of values within its 95% confidence interval (CI).

Results. The final sample consisted of 65 athletes who continued participating in rugby and 13 who discontinued. There was clear evidence that the mean value representing commitment with one's coach was lower for athletes who continued compared to those who dropped out (Cohen's d, -0.63, 95%CI, -1.22 to -0.33). Further, there was some evidence that the

mean value representing amotivation was higher for athletes who continued to drop out (0.47, -0.13 to 1.07). There was some evidence that complementarity with one's coach was lower for athletes who continued (-0.43, -1.03 to 0.17). Differences between athletes who continued and those who dropped out in closeness with their coach, task-related and ego-related goal orientations, and each of the three facets of basic needs satisfaction (i.e., the need for autonomy, competence, and relatedness) had 95%CIs that were too wide to provide useful evidence.

Interpretation. Consistent with theoretical predictions, our findings provide some evidence of a difference in the degree of self-determined motivation between athletes who continued and those who had dropped out, with the latter reporting higher levels of amotivation. Somewhat diverging from theoretical expectations, our study revealed that commitment to and complementarity with ones coach were lower among athletes who continued. This suggests that dropout among the athletes in this sample might be attributed directly to changes in coaching personnel and the opportunity to engage in competitive rugby elsewhere under the guidance of a specific coach (e.g., in another country).

OP-AP19 Swimming

POSTPONING EARLY MORNING TRAINING FOR SWIMMERS – THE EFFECT ON SLEEP, PERFORMANCE AND FATIGUE

BRANDTS, M., SKORSKI, S., MEYER, T.

SAARLAND UNIVERSITY

INTRODUCTION: Previous research has shown that swimmers sleep less prior to early morning training compared to a rest day (Sargent et al., 2014). Whether sleep can be extended by postponing the early morning training has not been investigated thus far. Moreover, it is unclear which effect this might have on performance and perceived fatigue. Therefore, the aim of the current study was to assess the effect of postponed morning training on sleep, performance and perceived fatigue in swimmers.

METHODS: Employing a randomized cross-over design, this study involved twenty-seven national level youth swimmers (13F, 14M; age: 16 ± 1 y) participating in two 8-day training camps. For the duration of the camp, training commenced at 7 a.m. (early training: ET) or at 9 a.m. (late training: LT). Sleep was measured daily using the ActiGraph wGT3X-BT (ActiGraph LLC, Pensacola, FL, USA) alongside a sleep diary. Perceived fatigue was recorded daily using the Short Recovery and Stress Scale for Sport. Performance assessments, comprising 100 m and 800 m all-out tests, were conducted at the start (Pre) and end (Post) of each training camp. The effect of postponed early morning training on sleep duration and perceived fatigue was analyzed using multilevel linear modeling, while performance outcomes were assessed using a two-way analysis of variance (ANOVA).

RESULTS: Sleep duration was significantly greater in ET compared to LT. (ET: 6.9 ± 0.7 h vs. LT: 7.9 ± 0.7 h; mean difference (md): 1.0 ± 1.7 h; $P < 0.001$; $\eta 2p = 0.27$). No significant intervention x training camp interaction effect was observed for 100 m performance ($F(1,20) = 0.72$; $P = 0.41$; $\eta 2p < 0.01$) or 800 m performance (F-(1,20) = 0.02; $P = 0.88$; $\eta 2p < 0.01$). However, perceived stress was significantly lower (ET: 3.4 ± 1.0; LT: 2.5 ± 0.9; med: -0.9 ± 2.5; $P < 0.001$; $\eta 2p = 0.13$) and perceived recovery significantly higher (ET: 2.7 ± 0.8; LT: 2.9 ± 0.7 ; md: 0.2 ± 2.0; $P = 0.027$; $\eta 2p = 0.01$) in LT compared to ET.

CONCLUSION: Postponing early morning training by 2 hrs is associated with extended total sleep time and improved perceived fatigue, but does not have an acute effect on performance. However, it could be speculated that extending sleep might be important in the long-term, considering the importance of perceived fatigue and sleep loss in the development of functional overreaching (Hausswirth et al., 2014).

STRENGTH TRAINING AND CONDITIONING LEADING TO A WORLD RECORD AT THE 2023 FUKUOKA WORLD CHAMPIONSHIPS: A CASE STUDY OF HAIYANG QIN

SHU, Y., CHENG, Y.

CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: This study investigates the influence of strength training and conditioning on specialized swimming techniques, focusing on Haiyang Qin, an elite Chinese male breaststroke swimmer. Spanning from 2022 to 2023, a critical period in Haiyangs career, it examines the interplay between his physical training, rhythmic training, and physiological adaptations. The aim was to elucidate how these factors synergistically contributed to his success in winning gold medals in the 50m, 100m, and 200m breaststroke events, thereby offering valuable insights into competitive swimming training.

METHODS: The study employed the following methods: (1) Training session analysis: A comprehensive examination of both aquatic and land-based training regimens, including specific swimming training and perceived exertion ratings (RPE) reported by coaches and athletes, along with monitoring of blood biochemical markers. (2) Functional testing and morphological changes: Regular assessments were carried out to evaluate morphological indicators and physical capabilities such as power and strength (Vertical Jump and Pull-up Test), speed (30 Metre Sprint Test), coordination (Y-Balance Test) and endurance (3 km Run Test). (3) Competition technical analysis: A systematic comparison was made of Haiyang Qins technical performance at the Fukuoka Championships with his previous results, with a focus on biomechanical changes and performance enhancements.

RESULTS: (1) High-intensity land-based training sessions (RPE: 8.4±0.9) exhibited a significant correlation with physiological markers such as testosterone levels. Additionally, significant changes in morphology were observed, particularly in chest circumference (101cm to 107cm) and weight (84kg to 93kg). (2) Increases in strength, core stability, agility, and power output led to significant improvements in Vertical Jump and Y-Balance Tests. (3) Specific-swimming performance showed significant enhancements, including a 7.1% increase in stroke rate in the 100m event and a 3.8% increase in stroke length in the 200m event during the Fukuoka Championships.

CONCLUSION: The findings indicate that a multi-approach strength training and conditioning program enhances the athletic physique, lower limb strength, and coordination. These improvements played a vital role in Haiyang Qins technical adjustments, resulting in his outstanding performance at the Fukuoka World Championships. The study highlights the potential benefits of a multi-approach physical training program for swimmers, providing valuable insights for coaches and athletes.

THE RELATIONSHIP BETWEEN TRUNK STRENGTH AND TURN TIME IN 400 M FREESTYLE FOR SWIMMING ATHLETES

ZHONG, J., GAO, H., ZHANG, C., WANG, D.
SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: Turn time (TT) plays a crucial role in competitive swimming performance. Its proportion in freestyle races spanning from 100 m to 1500 m ranges between 19.69% and 36.87% [1]. The longer the distance is, the more important TT. Of which, 400 m freestyle requires athletes to have both speed and endurance, and a large number of turns can be analysed. Rotation is the main phase of the turn in swimming. It involves entire body movement around the transverse and longitudinal axes [2]. This necessitates engagement of the trunk muscles to facilitate swift and smooth rotations. Therefore, this study aimed to investigate the correlation between trunk strength and TT in 400 m freestyle among swimming athletes.

METHODS: Thirteen regional swimming athletes (8 males: 18.63 y, 185.75 cm, 75.88 kg and 5 females: 16.6 y, 169.2 cm, 55.7 kg), whose average best records were 91.71% (male) and 86.86% (female) of the world records respectively, participated in the 400 m freestyle test. Data include total TT, single 15 m-turn (5 m-in: the time from 5 m to wall contact; plus 10 m-out: the time of 10 m after wall contact) in 7 turns for each participant. Trunk strength was assessed during flexion and extension using an isokinetic dynamometer (IsoMed-2000) at speeds of 60°/s and 180°/s, and bilateral trunk rotation was measured at speeds of 90°/s and 150°/s. Pearson correlations were computed between TT parameters and trunk isokinetic peak torque (PT).

RESULTS: Pearson correlation showed significant negative correlations between total TT and trunk flexion ($r = -0.61$, $P = 0.027$) and extension ($r = -0.575$, $P = 0.04$) PT at 60°/s respectively. Similarly, strong to very strong correlations were observed for trunk rotation at 90°/s and 150°/s (left: $r = -0.737 \sim -0.77$, $P = 0.002 \sim 0.004$; right: $r = -0.659 \sim -0.686$, $P = 0.01 \sim 0.014$). Besides, the correlations from the first turn to the last turn gradually increased every single 15 m-turn, significantly in flexion 60°/s (from $r = -0.56$ to -0.639), left rotation 90°/s and 150°/s (from $r = -0.646$ to -0.8), and right rotation 90°/s and 150°/s (from $r = -0.547$ to -0.782). The higher correlation of left than right side may be caused by the habit of each participant's rotation. After splitting the TT to 5 m-in and 10 m-out, the total 5 m-in time was negatively correlated with bilateral rotation in both 90°/s and 150°/s ($r = -0.56 \sim -0.644$, $P = 0.018 \sim 0.046$). However, the total 10 m-out time was correlated with flexion (60°/s and 180°/s), extension (60°/s), and bilateral rotation in both 90°/s and 150°/s ($r = -0.601 \sim -0.806$, $P = 0.003 \sim 0.001$).

CONCLUSION: The findings suggest that (1) trunk flexion, extension, and bilateral rotation strength are strongly correlated with TT; (2) the higher correlation of left than right may be caused by habitual turning direction; (3) this correlation may strengthen as the distance increases; (4) the correlations were higher in 10 m-out phases than 5 m-in phases.

ADVANCING ARTISTIC SWIMMING BIOMECHANICS AND OFFICIATING THROUGH MEDIAPIPE-BASED ANALYSIS OF THE BALLET LEG TECHNIQUE.

EDRISS, S., CAPRIOLI, L., BONAIUTO, V., ANNINO, G.
TOR VERGATA UNIVERSITY

INTRODUCTION: In certain sports, such as Artistic Swimming (AS), the evaluation of player performance and the assessment of penalties are linked to the jury. This requires players to execute their routines within the lateral purview of the referees. In addition, deviations from specific AS techniques contribute to point deductions through penalties. Prompt and precise deviation monitoring is an important requirement. Such monitoring aids coaches in strategic planning during the training sessions, and guides referees to monitor this matter. However, technology benefits in AS are generally limited,

and decisions were principally made by on-site judges who observed the performances live. This study introduces a marker-less Python-based MediaPipe system to recognize body elements, focusing on the Ballet Leg technique to measure deviations and assess swimmers biomechanics. In this technique, the deviation is defined as a leg angle that is either more or less than 90°, indicating whether the leg is oriented vertically or not relative to the horizontal plane, and more degree deviations, reduce more points. The scoring scale in penalty measurement of one leg execution is that the deviation up to 15 degrees reduces 0.2 points, between 15 to 30 degrees reduces 0.5 points, and over 30 degrees deducts 1 point. Validation involves comparing results with the suggested method via Kinovea software (Version 0.9.5, USA) in 2D AutoCAD 2019 (Autodesk, Inc.) as the gold standard method in this project.

METHODS: Twenty AS athletes, with an average age of 15±2 and over 3 years of experience, executed a Ballet Leg technique during training sessions. Two GoPro9 recordings, positioned 2 meters laterally from the swimmers at the pool edge with one camera placed 30 cm under and the other 25 cm above the water surface, captured the swimmers performance. The peak performance deviation was measured using MediaPipe, Kinovea, and 2D AutoCAD. The data similarity was measured by analyzing deviation angles between the two software and the gold standard by calculating the correlations using Orange3 Software.

RESULTS: The statistical analysis revealed strong correlations between the measurements obtained using MediaPipe and the gold standard (Pearson correlation coefficient = 0.92, RMSE = 2.3). Plus, the comparison of Kinovea with the gold standard demonstrated an even higher correlation (Pearson correlation coefficient = 0.99) and a notably lower RMSE score (0.6), indicating a high level of accuracy in the Kinovea kinematic measurements.

CONCLUSION: The results obtained through MediaPipe demonstrate similarity with the gold standard, establishing its capability to evaluate AS techniques including Ballet Leg. Particularly, its real-time and offline deviation calculation capabilities surpass the limitations of manual alternatives like Kinovea. While technology usage is limited in official AS officiating, coaches can get the benefits of MediaPipe to access accurate biomechanics-designed data and receive quick and precise feedback.

A STUDY ON THE ABILITY TRANSFER OF CHINESE SWIMMERS IN SINGLE MIDDLE AND SHORT DISTANCE EVENTS

SHANG, M., CHENG, Y.
BEIJING SPORT UNIVERSITY

INTRODUCTION: According to statistics, the number of medals in the four strokes of 50m, 100m and 200m accounts for 77% of the medals at the World Championships. Swimmers usually excel in 1-2 of these distances, and outstanding swimmers are able to achieve all-around development by excelling in 3 distances. However, it is rare for top swimmers to achieve excellence in a single event at 50m, 100m and 200m distances and win medals in all of them. At the 2023 World Championships, Chinas breaststroke swimmer Qin Haiyang achieved a historic achievement in the 50m, 100m and 200m breaststroke events, creating a trio of titles. At the same World Championships, Kaylee McKeown dominated the backstroke events, winning all three titles. These achievements highlight the fact that competing and excelling in multiple events has become a new competitive trend. This study delves into the migration of Chinese swimmers ability to compete in a single short- and middle-distance event, and promotes multi-event participation and multidimensional skill enhancement in swimmers, which is believed to enhance the overall competitiveness and depth of talent in the sport.

METHODS: The search results were analyzed on China Knowledge and Google Scholar using the keywords "swimming ability", "transfer learning" and "multisport development", combined with interviews with Chinese swimming team coaches and researchers. The results were analyzed.

RESULTS: During the period 2016-2023, two Olympic Games and four World Championships were held. In the 2016 Rio Olympics, there were six champion-cum-athletes; in the 2017 Budapest World Championships, there were 12 champion-cum-athletes; in the 2019 Gwangju World Championships, there were 13 champion-cum-athletes; in the 2021 Tokyo Olympics, there were 14 champion-cum-athletes; in the 2022 Budapest World Championships, there were 17 at the 2022 World Championships in Budapest; and 17 at the 2023 World Championships in Fukuoka. As of February 2024, there are 17 times in the history of the World Championships in the 50-100-200 meters can achieve both medals, of which the number of athletes in the 2019 and 2023 World Championships in the 50-100-200 meters at the same time to win medals are three, which reflects that in recent years the swimming world of the ability of athletes to participate in multiple events in the level of training to obtain a greater improvement. In particular, Chinas Luo Xuejuan, Zhang Yufei and Qin Haiyang were among the 17 people mentioned above. In terms of strokes, there are 6 breaststroke, 4 freestyle, 3 backstroke and 1 butterfly, reflecting that breaststroke is easier to migrate in ability. 2023 World Championships at the same time, there are 2 people at the same time to take the small event Grand Crown.

CONCLUSION: The study of kinematic characteristics, departure and stroke kinetics characteristics, energy metabolism characteristics, and specialized fitness characteristics of short- and middle-distance swimmers is the key to solving the synergistic develop

OP-AP18 Sprint Training

DOES THE SELECTION OF RESISTANCE FOR LIGHT LOAD RESISTANCE RUNNING TRAINING NEED TO BE PERSONALIZED

GUO, Q., YUAN, T.

CHINA INSTITUTE OF SPORT SCIENCE

INTRODUCTION: Resistance running(RS) is widely recognized as the most commonly used and effective method to enhance speed performance and overcome speed barriers in sprint training. Some studies have employed body mass (bm) as a benchmark, revealing that varying percentages of body mass as resistance yield different training effects. For instance, 12.5%bm RS enhances high-speed acceleration phases. Another study utilized 10%bm, 30%bm, and 50%bm for resistance running training, suggesting that faster and stronger athletes may require relatively heavier resistance to attain their training goals. This study investigates resistance ranging from 1% to 10%bm, aiming to determine if athletes with different physical characteristics benefit from personalized resistance for achieving specific training goals within this range.

METHODS: Twenty-nine elite track and field athletes participated in this study, comprising 18 male and 11 female athletes. All athletes underwent the same warm-up procedure, followed by a squat 1RM test and a 30m sprint test without resistance （T-133 timing system，eliga，china）on the same day. Within one week of the initial test, the athletes engaged in resistance running training（T120-sprint training device，eliga，china）. The resistance was set between 1%-10% of the athletes body weight(bw), and the 30m times were recorded, above test excluding reaction time. Linear regression analysis was conducted using SPSS software to assess the impact of gender, weight, and relative strength (squat 1RM/body weight) on the rate of speed decline.

RESULTS: The average time for the 30m sprint without resistance was recorded at 3.835 seconds, with a standard deviation of 0.123 seconds. The average relative strength was measured at 2.100, with a standard deviation of 0.251, and the average rate of speed decline was found to be 15.37%, with a standard deviation of 3.613%. For female athletes, the average 30m sprint time was 4.087 seconds, with a standard deviation of 0.133 seconds; the average relative strength was 1.818, with a standard deviation of 0.217; and the average rate of speed decline was 21.281%, with a standard deviation of 6.679%.Linear regression analysis revealed that resistance as a percentage of body weight, within the range of 1%-10% (B=1.635, $p<0.01$), and gender (B=0.079, $p<0.01$) significantly influenced the rate of speed decline. However, relative strength (B=-0.048, p=0.144) and the finish time for the sprint without resistance (B=-0.110, p=0.074) did not show a significant effect on the rate of speed decline.

CONCLUSION: The findings of this study indicate that in resistance running training, when the load is below 10% of body weight (bw), the trend of speed decline is roughly similar across athletes of different strength levels as resistance increases. However, gender and the amount of load are significant factors affecting the rate of speed decline, with female athletes experiencing a slightly higher rate of decline compared to male athletes. This suggests that when des

THE EFFECTS OF COMBINED RESISTED AND MAXIMUM VELOCITY SPRINT TRAINING ON THE SPRINT PERFORMANCE OF TEAM SPORT PLAYERS

WARD, C., Ó CATHÁIN, C., NÍ CHÉILLEACHAIR, N., KELLY, D.T.

TECHNOLOGICAL UNIVERSITY OF THE SHANNON, ATHLONE, IRELAND.

INTRODUCTION: The development of acceleration and maximum velocity (MV) sprint performance are key goals for field-based invasion team sport (FITS) coaches. Resisted sprint training (RST) has been shown to be an effective method for improving acceleration performance when using a broad range of loading magnitudes [1], yet there are concerns regarding the potential of 'very heavy' loaded RST to negatively impact MV performance [2]. Alternatively, flying sprints are used by coaches when targeting MV improvements [3]. However, no research has investigated the efficacy of a concurrent RST and maximum velocity sprint training (MVST) protocol. This study aimed to determine the effectiveness of a combined RST and MVST approach on the in-season acceleration and maximum velocity performance of FITS players.

METHODS: Elite level, male hurling players were assigned to an experimental group (EG) (n=21) or a control group (n=19). In addition to their regular training, the EG performed two sessions (1 x RST, 1 x MVST) per week for 8 weeks, while the control group performed unresisted sprinting (5-20m repetition distance range). RST was performed with a 50% Vdec load and a constant repetition distance of 15m, while MVST consisted of 8-12m flying sprints with a 25m build-up phase. Sprint, strength, and jump performance were measured at 1-week pre and post intervention.

RESULTS: The EG displayed significant small within-group (pre to post) improvements in 5m (d = 0.57) and 10m (d = 0.44) split times, and MV (d = 0.35), while a significant moderate increase in SLJ performance (d = 0.89) was also found. A significant decrease in reactive strength (d = 0.42) and increase in relative strength (d = 0.53) were detected for the CG. Finally, there were significant time effects for first step flight time (FT) (p = 0.004) last step FT (p = 0.035), and the 10-20 m split time (p = 0.018).

CONCLUSION: Performing a weekly combination of very-heavy RST and MVST across an 8-week in-season training block can yield improvements in both early acceleration and MV sprint performance. Additionally, study findings dampen previ-

ous concerns regarding the potentially negative impact of heavy-loaded RST on MV. Our study highlights the utility of this RST (using 8 sleds) and MVST approach within FITS settings, integrated prior to collective in-season sports training using a short 20-minute time slot.

RELATIONSHIPS BETWEEN LOWER LIMB MUSCLE VOLUME, MUSCLE STRENGTH AND SPRINT PERFORMANCE IN ELITE ATHLETES

GIROUX, C.1, MACCHI, R.1, PIECUCH, L.2, HEGYI, A.3,4, HOLLVILLE, E.1, MATEUS, D.2, FORNASIER- SANTOS, C.1, SLAWINSKI, J.1, MORIN, J.B.5, LACOURPAILLE, L.4, COUTURIER, A.1, NORDEZ, A.4, RABITA, G.1, GUILHEM, G.1

1. FRENCH INSTITUTE OF SPORT, SEP, EA 7370, PARIS, FRANCE 2. ÉCOLE CENTRALE NANTES, LS2N, UMR CNRS 6004, NANTES, FRANCE 3. HUNGARIAN UNIVERSITY OF SPORTS SCIENCE, BUDAPEST, HUNGARY 4. NANTES UNIVERSITÉ, MIP, UR 4334, NANTES, FRANCE 5. LIBM, JEAN-MONNET UNIVERSITY, SAINT-ETIENNE, FRANCE

INTRODUCTION: High-speed running is fundamental to perform in various sports. Muscle morphological (volume) and functional characteristics (strength) are recognized to be associated with sprint performance [1,2] and seem to influence sprint force-power-velocity (FPV) relationship [3]. This study aimed to identify the relationships between sprint maximal velocity (Vmax), theoretical maximal power (Pmax) and force (F0) derived from the sprint FVP profiles, and lower limb muscle characteristics including volume inferred from automatized MRI scans segmentation in elite athletes.

METHODS: Seventy-two athletes (33 women, 39 men, age: 24.3 ± 3.3 years, height: 1.77 ± 0.09 m, mass: 74.2 ± 12.9 kg) of rugby 7, track and field, and bobsleigh performed two 40-m sprints. Vmax and FVP relationship were assessed using radar-based velocity measurements. F0 and Pmax were calculated from the FPV relationship. Maximal isometric (MVC) and eccentric (ECC) torque, and rate of torque development (RTD) were assessed during hip, knee and ankle extension and flexion (except for ankle).

The volume of 18 lower limb muscles including gluteus, quadriceps, hamstrings and adductors groups was automatically extracted from Magnetic Resonance imaging (MRI) using Deep Learning method [4] for 24 athletes (14 women and 10 men).

Multiple linear regressions (Forward method) were conducted to identify significant predictors of Pmax, F0 and Vmax (dependant variables) from the functional characteristics and then the 18 muscle volumes (independent variables).

RESULTS: Vmax exhibited significant correlations with the volume of the vastus intermedius (VI), gluteus minimus (Gmin), biceps femoris short head (BFsh) and semitendinosus (ST) muscles ($r2 = 0.62$, $P < 0.05$). Pmax showed significant correlations with VI, BFsh, gluteus maximus (Gmax) and ST volumes ($r2 = 0.70$, $P < 0.05$) whereas F0 showed significant correlations with VI and Gmax volume ($r2 = 0.58$, $P < 0.05$).

Furthermore, Vmax was significantly correlated with plantar flexor RTD and hip flexor MVC ($r2 = 0.20$, $P < 0.05$) whereas Pmax and F0 were both significantly correlated with plantar flexor RTD and knee flexor MVC ($r2 = 0.18$ and $r2 = 0.13$, respectively, $P < 0.05$).

CONCLUSION: This study shows that a significant part of sprint performance variability could be explained by hip flexors and knee extensors muscle volume. Joint strength testing seems also to partly explain sprint performance. Hip extensor and knee flexor muscles could be targeted in training programs to maximize sprint performance. While these findings are consistent with previous studies [1,5,6], they suggest to further explore the relationship between muscle morphology, functional capacity and sprint performance, particularly for thigh muscles.

EFFECTS OF LOW-VOLUME COURT-BASED SPRINT INTERVAL TRAINING ON AEROBIC CAPACITY AND SPORT-SPECIFIC ENDURANCE PERFORMANCE IN COMPETITIVE TENNIS PLAYERS

LIU, H.1,2, YANG, W.1, LI, Q.1,2, POON, E.T.3, HO, I.M.K.4,5, LIU, H.1, BAO, D.1, GUO, Y.1, LI, Y.1

1 BEIJING SPORT UNIVERSITY;2 UNIVERSITY OF LIMERICK; 3 THE CHINESE UNIVERSITY OF HONG KONG;4 TECHNOLOGICAL AND HIGHER EDUCATION INSTITUTE OF HONG KONG;5 ASIAN ACADEMY FOR SPORTS AND FITNESS PROFESSIONALS;

INTRODUCTION: Sprint interval training (SIT) is a potent exercise strategy to enhance athletes aerobic capacity in a time-efficient manner. The purpose of this study was to examine the effect of a low-volume court-based SIT program on aerobic capacity and sport-specific endurance performance for competitive tennis players.

METHODS: Sixteen competitive collegiate tennis players were randomly assigned to the SIT (court-based repeated-sprint training) and traditional endurance training (ET; 45-min continuous treadmill running) groups for a 6-week intervention (3 sessions/week). The maximal oxygen uptake (VO2max), minute ventilation at peak exercise (VEmax), ventilatory anaerobic threshold in percentage of VO2max (VT/VO2), and elimination rate of blood lactate (BLAer) were assessed, whereas the

Yo-Yo Intermittent Recovery Test Level 2 (YoYo-IR2) and the tennis-specific HIT&TURN test were conducted at baseline and after the intervention.

RESULTS: Both SIT and ET showed significant improvements in VO2max ($p < 0.01$) with moderate effect sizes (ES=0.64 and 0.98, respectively), as well as in VEmax ($p < 0.01$) with small effect sizes (ES=0.23 and 0.21, respectively), and VT/VO2 ($p < 0.01$) with large effect sizes (ES=2.37 and 3.85, respectively). The BLAer improved significantly in SIT (ES=1.03; $p < 0.05$) whereas no significant changes occurred in ET. The magnitude-based decision showed a clear and superior improvement in both YoYo-IR2 (ES=0.69) and HIT&TURN (ES=1.72) tests in SIT than ET.

CONCLUSION: Compared with traditional ET, court-based SIT can be a time-efficient strategy to improve aerobic capacity and tennis-specific endurance without requiring specialized equipment for competitive tennis players.

COMBINATION OF WEIGHT REDUCTION AND HYPOXIA ON PSYCHOPHYSIOLOGICAL RESPONSES TO A HIGH-INTENSITY EXERCISE IN ATHLETES: PRELIMINARY DATA

CHAMBION-DIAZ, M., PIALOUX, V., BILLAUT, F.

UNIVERSITÉ CLAUDE BERNARD LYON 1, LYON, FRANCE & UNIVERSITÉ LAVAL, QUÉBEC, CANADA

INTRODUCTION: The AlterG treadmill allows weight reduction during running, which lowers mechanical stress. This tool therefore has great potential applications in return from injuries and to maximize training benefits under lower mechanical stress in healthy athletes. However, there is no strong evidence regarding the beneficial effect of AlterG running on athlete's physical performance. Moreover, reducing mechanical load might potentially decrease physiological stress and subsequent adaptations. Hypoxia is well known to increase metabolic stress and may thus offer a countermeasure to optimize the benefits from weightless running in varied training scenarios. To date, there is no study examining physiological responses to such training strategy. The aim of this study is to verify the feasibility of combining running with body weight reduction and hypoxia during high-intensity interval exercise, and characterize the psychophysiological responses to such exercise-environment combination.

METHODS: Twenty-two participants volunteered for the project, but only three (2 men, 1 woman, age:24.6 years, height:168.3cm, weight:66.7kg, VO2max:62ml/min/kg) completed the protocol to date. Participants completed a high-intensity interval training (HIIT) session on an AlterG treadmill in the following 5 experimental conditions in randomized order: normoxia at 100% body weight (BW); normoxia at 80% BW; normoxia at 60% BW; hypoxia ($FIO2 = 14\%$) at 80% BW; hypoxia at 60% BW. The HIIT session included 3 sets of 8 repetitions of 30 seconds of effort performed at 110% of the maximum aerobic speed, interspersed with 30 seconds of passive recovery. During the session, heart rate (HR), pulse arterial O2 saturation (SaO2), muscle deoxyhemoglobin (HHb) concentration and rate of perceived exertion (RPE) were continuously recorded. Blood lactate concentration was measured post-session.

RESULTS: Weight reduction by AlterG increased SaO2 by 3% and reduced both HR by 27bpm and RPE by 2.4 points compared to control ($p<0.05$). When hypoxia was added, SaO2 was reduced by 9 to 13% compared to the 3 other conditions in normoxia with varied weights. HR was lower in all conditions compared to control ($p<0.05$). RPE was higher in hypoxia by 1 point compared to the 2 other conditions in normoxia and weight reduction ($p<0.05$). Hypoxia increased [HHb] by 21 mmol compared to the 2 other conditions in normoxia and weight reduction ($p<0.05$). There was no significant difference in [lactate] at the end of the effort across conditions ($p=0.08$).

CONCLUSION: These preliminary data suggest that mechanical load and hypoxia differently modulate psychophysiological responses to high-intensity exercise in a different way. Further analyses will allow us to confirm these initial observations and to ascertain whether biological sex mediates these phenotypic responses.

OP-MH26 Exercise and peripheral artery disease

EFFECTS OF ARM-CRANK EXERCISE ON CARDIOVASCULAR FUNCTION IN PATIENTS WITH PERIPHERAL ARTERY DISEASE: A RANDOMISED CONTROLLED TRIAL

CUCATO, G., WILHELM, E.1, KANEGUSUKU, H.2, WOLOSKER, N.2, CORREIA, M.A.3, RITTI-DIAS, R.M.3

1-NORTHUMBRIA UNIVERSITY, UK; 2-HOSPITAL ISRAELITA ALBERT EINSTEIN, BRAZIL; 3-UNIVERSIDADE NOVE DE JULHO, BRAZIL.

INTRODUCTION: Arm-crank exercise training (ACT) is an alternative exercise modality for patients with peripheral artery disease (PAD) due to the attenuation of pain symptoms during the exercise and the benefits on functional capacity. However, the benefits of ACT on cardiovascular function in PAD are unknown.

METHODS: This is a three-armed randomised, prospective, single-blind data collection, single-centre study. Forty-two patients of both sexes were randomised into 3 intervention groups: ACT, (N=14, age=69±7 years) walking training (WT, N=15, age=68±7 years), and the control group (CO, n=13, age=65±8 years). The ACT and WT performed 2 supervised sessions/week for 12 weeks, 15 to 10 sets of 2 to 5 minutes at 13 to 15 score on the Borg scale. Patients in the CO attended meetings twice a week for 12 weeks with the research team. During these meetings, they engaged in manual tasks using materials, cultural programs, cooking classes, and home care without any exercise components. Before and after 12

weeks of interventions, cardiovascular parameters [office, ambulatory and central blood pressure, heart rate variability (high frequency/low frequency)], and arterial stiffness (pulse wave velocity) were obtained. We performed generalised estimating equations and a post hoc pairwise comparison using the Bonferroni correction for multiple comparisons. A level of significance (α)<0.05 was assumed in this study. All data are expressed as mean±SD.

RESULTS: Compared to baseline, office systolic (ACT =-7.5±18.2; WT=-6.2±14.6 and CO=-7.0±8.8 mm Hg), office diastolic (ACT=-4.0±7.9; WT=-5.0±7.0 and CO=-4.5±4.5 mm Hg), central systolic (ACT =-8.3±18.6; WT=-8.5±18.2; and CO=-11.2±15.9) and central diastolic blood pressure (ACT=-5.5±8.6; WT=-4.5±7.7; and CO=-5.0±10.4) decreased significantly post-intervention in all groups (time effect p<0.05). In contrast, compared to baseline, there were no changes in all groups for pulse wave velocity (ACT=0.2±0.8; WT=-0.6±2.8 and CO=-0.5±2.3 m/s), high frequency/low frequency (ACT=-0.0±0.6; WT=0.1±0.7 and CO=-0.0±0.7), 24 hours systolic (ACT=-4.8±14.4; WT=1.2±5.3 and CO=-1.1±4.8 mm Hg), 24 hours diastolic (ACT=-4.1±7.0; WT=-2.9±4.6 and CO=-3.4±7.0 mm Hg), and 24 hours mean blood pressure (ACT=-4.4±9.1; WT=2.4±4.3; and CO=-2.7±7.9 mm Hg), all P>0.05

CONCLUSION: In PAD patients, ACT promotes similar cardiovascular benefits to WT and CO groups. Consequently, ACT can be integrated into broader PAD management strategies to reduce cardiovascular risk in these patients.

IMPACT OF ATHEROSCLEROTIC LOWER LIMB PERIPHERAL ARTERY DISEASE ON THE RISK OF CAROTID PLAQUE INSTABILITY: EFFECT OF PHYSICAL FITNESS LEVEL.

RIVOIRE, E., MURA, M., JOSSET, L., DEHINA-KHENNICHE, A., MILLON, A., LONG, A., PIALOUX, V.

HÔPITAL CARDIOLOGIQUE LOUIS PRADEL

INTRODUCTION: Lower extremities peripheral arterial disease (LE-PAD) associated with carotid atherosclerotic plaques increases the risk of ischemic events. Atherosclerotic patients with both LE-PAD and carotid plaque are at higher risk of unstable plaques1, which may be due, in part, to an increased level of chronic systemic low-grade inflammation. This may thereby place these individuals at a greater risk of stroke1, with more severe atherosclerotic damage2 and limitations to walking3 as compared to patients with only carotid plaque. Benefits of regular physical activity (PA) on morbidity, mortality and long-term quality of life were previously demonstrated in LE-PAD patients. Objective: Evaluate the effect of LE-PAD and PA on the risk of carotid plaque instability.

METHODS: In this study, patients with carotid plaque with a stenosis >50% were divided in two groups: LE-PAD (+) and LE-PAD (-), according to ankle brachial index (ABI) or history of revascularization. Characterization of carotid plaque instability was evaluated by magnetic resonance imaging (MRI). PA and sedentary behavior were assessed by questionnaires and physical fitness by quadriceps strength and 6-minutes Walking Test (6-MWT).

RESULTS: Fifty-two patients were included in this study (30 and 22 in LE-PAD (+) and (-) groups respectively). In LE-PAD (+) group the non-physically active patients (<1600 MET.min/weeks) and sedentary patients (>8h/day) had higher intraplaque haemorrhage (IPH) compared to physically active (p=.017) and non-sedentary patients (p=.06) respectively. Whereas these differences were not observed in LE-PAD (-) group. In the LE-PAD (-) group, 6-MWT distance was higher in the physically active patients compared to the non-physically active one (p<.00.1). On the contrary, there was no difference in 6-MWT distance between active and non-physically active subjects in the LE-PAD (+) group, suggesting that LE-PAD likely inhibits the impact of PA on the walking distance capacity.

CONCLUSION: Patients with carotid plaques and LE-PAD may represent a subgroup at higher risk of cardiovascular-related complications, with greater plaque instability. However, increased PA and reduced sedentary behavior may limit these risks.

Conclusion: In the long term, systematic evaluation of lower limb vasculature by ABI measurement and completion of personalized PA may be beneficial for LE-PAD patients with carotid plaques.

CUTANEOUS BLOOD FLOW MODULATES ASSESSMENTS OF MUSCLE OXYGENATIONS: COMPARISONS OF CONTINUOUS-WAVE AND TIME-RESOLVED NEAR-INFRARED SPECTROSCOPY

KUNIMASA, Y., AMANO, T.1, OKUSHIMA, D.2, KOGA, S.3

1 NIIGATA UNIVERSITY, NIIGATA, JAPAN; 2 NAGAOKA UNIVERSITY OF TECHNOLOGY, NIIGATA, JAPAN, 3 KOBE DESIGN UNIVERSITY, HYOGO, JAPAN

INTRODUCTION: Near-infrared spectroscopy (NIRS) is a non-invasive technique to assess skeletal muscle oxygenation during exercise. Studies suggested that changes in skin blood flow (SkBF) would alter tissue oxygenations assessed by a conventional continuous-wave NIRS (CW-NIRS) which evaluates relative changes in muscle oxygenations (Buono et al. 2005; Koga et al. 2015). The time-resolved NIRS (TRS-NIRS), which can assess absolute changes in tissue oxygenations, has been suggested to be less influenced by the increases in SKBF, but not entirely insensitive (Koga et al. 2015). For both CW-NIRS and TRS-NIRS, eliminating potential changes in SkBF during the assessment of muscle oxygenations may improve physiological interpretation. We therefore investigated how a transdermal administration of adrenaline to induce sustained cutaneous vasoconstriction alters the assessment of muscle oxy- and deoxygenations during passive heating.

METHODS: Eleven healthy males received 0.1% adrenaline into the medial gastrocnemius muscle using transdermal iontophoresis (0.5 mA, 20 min) to stimulate alpha adrenaline receptors inducing sustained cutaneous vasoconstrictions. After the normothermic baseline recording, participants were passively heated by wearing a water perfusion suit (47 °C) with concomitant elevations of ambient temperature to 35 °C for 60 minutes. SkBF, muscle oxy- and deoxygenation of hemoglogin+ myoglobin (Oxy [Hb+Mb] and deoxy [Hb+Mb]), total [Hb+Mb], and optical factors (path length: PL, scattering

coefficient: SC, and absorption coefficient: AC) were assessed at the site with and without (control) adrenaline treatments. Rectal and skin temperatures were assessed to evaluate the magnitude of heat stress.

RESULTS: Heat stress elevated skin temperature by approximately 4 °C (P<0.001) while the elevation was small in rectal temperature (by 0.1 °C, P<0.01). Administration of adrenaline attenuates baseline SkBF by half (51%) of the control site. Cutaneous vasodilation was significantly suppressed at the adrenaline-treated site during heat stress as the changes were 4- and 2-fold from baseline at control and adrenaline treatment sites, respectively (both p<0.001). Heat stress increased CW-NIRS-derived oxy [Hb+Mb] and total [Hb+Mb] at both control and adrenaline-treated sites but this was only seen at the control for the assessment of TRS-NIRS (all P<0.05). TRS-NIRS-derived deoxy [Hb+Mb] at the control site was decreased by the heating (P<0.01), but not at the site with adrenaline treatments.

CONCLUSION: The reduced SkBF by the adrenaline treatment abolished heat stress-mediated muscle oxygenations assessed by TRS-NIRS but it remains sensitive to the response assessed by CW-NIRS. These results suggest that cutaneous adrenaline treatment (or any other equivalent intervention to reduce SkBF) is important to interpret NIRS-derived muscle oxygenations when significant cutaneous vasodilation is expected. Notably, this treatment is more effective for assessing muscle oxygenations using TRS-NIRS.

IGF-1 ALTERED THE REMODELLING CAPACITY OF TENDON CONSTRUCTS INDEPENDENTLY OF THE POST-EXERCISE SYSTEMIC ENVIRONMENT

GIANNOPOULOS, A., PAPADOPETRAKI, A., MAGNUSSON, S.P., PHILIPPOU, A., BACKMAN, L.B., SVENSSON, R.B.
LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Tendinopathies are characterised by an imbalance between extracellular matrix (ECM) production and degradation, leading to dysfunctional tendons. Exercise is considered the gold standard for managing tendinopathies. Further, exercise induces an anabolic environment with the accumulation of growth factors in the circulation, among them IGF-1 which is a fundamental factor for tendon remodelling. Additionally, it has been shown that injections with IGF-1 cause upregulation of protein and collagen synthesis in human tendons. Hence, we hypothesised that the exercise-induced biochemical environment would have an additive effect on IGF-1 bioactivity to matrix remodelling of human engineered tendons.

METHODS: Serum was isolated from blood samples (N=7 participants) that were collected within 10 minutes after a bout of exercise until exhaustion, on a cycle ergometer. Human tendon constructs were cultured with 10% human serum in the culture media for one week. Serum from each participant used separately for the following groups: Pre- (Pre-Ex+IGF-1) and post-exercise serum (Post-Ex+IGF-1) supplemented with IGF-1 (IGF-1), pre- (Pre-Ex) and post-exercise (Post-Ex) serum without IGF-1. Enzyme-linked immunosorbent assays were used to evaluate procollagen type I carboxy-terminal propeptide (PICP), extracellular matrix metalloproteinase inducer (EMPRIN) and matrix metalloproteinase-2 (MMP-2) proteins in the culture media that collected from the whole cultured period after the addition of human serum. Confocal microscopy was used to image whole mount constructs stained with collagen hybridizing peptide (CHP) to evaluate collagen degradation.

RESULTS: The CHP intensity did not reveal any differences between the conditions. PICP concentration revealed a 40.8% increase at pre-Ex+IGF-1 relative to the Pre-Ex (p=0,0016) group and 34.7 % in the Post-Ex+IGF-1 relative to the Post-Ex (p<0,0075) group. IGF-1 administration significantly enhanced EMMPRIN concentration (p<0.0001), which was increased by 18.7% at Pre-Ex+IGF-1 compared to Pre-Ex (p=0.0068), and 27,5% at Post-Ex+IGF-1 compared Post-Ex (p<0.0001) groups, with significant contribution of the exercise effect (p=0.0124). MMP-2 concentration was upregulated with the administration of IGF-1 (p=0.0010) and was 7.5% higher in the Pre-Ex+IGF-1 relative to the Pre-Ex (p=0.0120) group, and 6.4% higher in the Post-Ex+IGF-1 relative to the Post-Ex (p=0.0320) group.

CONCLUSION: Contrary to our hypothesis, the above results revealed that IGF-1 can regulate the ECM remodelling independently of the post-exercise environment. A combined effect of exercise and IGF-1 treatment was demonstrated in EMMPRIN secretion, indicating the involvement of MMP-mediated signalling pathways, providing a potential link between exercise and tendon remodelling.

HIGH ACCURACY OF THE A NEW DIGITAL INSOLE SYSTEM (WALKINSENSE) FOR THE MEASUREMENT OF SPATIOTEMPORAL PARAMETERS AT DIFFERENT SPEED CONDITIONS

ECKELT, M., FAYAD, J., SCHURMANS, G., BACKES, A., MEYER, T., GRIMM, B., MOUTON, C., SEIL, B., MALISOUX, L.
LUXEMBOURG INSTITUTE OF HEALTH

INTRODUCTION: The evaluation of spatiotemporal parameters during walking is helpful to detect abnormal gait or to quantify improvement resulting from interventions, in particular during rehabilitation in patients with orthopaedic conditions. For now, these measurements are mainly limited to laboratory testing. Gait monitoring of the patients in their natural environment during daily life activities would provide highly relevant information to clinicians. This study aims to assess the

validity of a new digital health solution, the WalkinSense system, which consists of pressure-sensitive insoles combined with inertial measurement units.

METHODS: Records of 104 healthy participants (mean age = 36 years, median bmi = 23.18, median height = 172.3cm, 50% female) were obtained during various speed conditions such as low speed walking, high speed walking and running (3km/h, 4.5km/h, 6km/h and 9km/h). Spatiotemporal metrics were derived from ground reaction force recordings collected with an instrumented treadmill (M-Gait, Motek Forcelink Amsterdam) and from the WalkinSense system. The corresponding metrics were calculated as mean over the total amount of steps of the participant, respectively. Mean bias between the two systems was assessed using separate Bland-Altman analyses for each metric and condition. Mean error and limits of agreement (absolute and percentage) were calculated and the agreement was statistically quantified using a priori set thresholds (excellent <5%, good<10%, acceptable<15% and poor >15%)[1]. A two-way mixed model intraclass correlation coefficient (ICC) for consistency was also calculated. ICC was considered poor<0.5, moderate 0.5-0.75, good 0.75-0.9 and excellent >0.9.

RESULTS: Excellent agreement was achieved for stride time and cadence across all different speed conditions (<5% error). In addition, excellent agreements were found for stance time, swing time and single support time for all walking speeds (3km/h, 4.5km/h and 6km/h) and good agreement for running (9km/h). Double support time showed acceptable agreement for all walking speeds. ICC values ranged from poor (swing time at 9km/h and double support time at 6 km/h) to excellent (e.g. stance time at 3 and 4.5km/h) across all metrics and conditions. Stride time and cadence showed excellent ICC values for all speed conditions expect for 9km/h, which yielded moderate ICC values.

CONCLUSION: These findings suggest that the WalkinSense system may be useful to quantify spatiotemporal metrics with generally excellent accuracy in walking speeds, which might be the decisive gait speeds, especially in rehabilitation. Future analyses will focus on the validation of important kinematic and kinetic variables in order to be able to estimate musculoskeletal loading.

EFFECT OF A SIMULTANEOUS APPLICATION OF ISCHEMIC PRECONDITIONING AND PLACEBO ON ISOMETRIC STRENGTH OF LOWER LIMBS

NASCIMENTO, B., ARAUJO, M.C.C., ROCHA, V.N., PRAZERES, E., PARISH, B., MAROCOLO, M.

FEDERAL UNIVERSITY OF JUIZ DE FORA, JUIZ DE FORA, MINAS GERAIS, BRAZIL.

INTRODUCTION: Knee injuries in physically active people are quite common, mainly those on ligamentous and meniscus, usually requiring arthroscopy surgery. For this surgery method, the tourniquet is used for blood flow occlusion but may cause muscle damage due to occlusion time and high pressure. Ischemic Preconditioning (IPC), consisting of brief periods of occlusion-reperfusion of blood flow can be a factor in tissue preservation. In this context, muscle biopsy becomes an excellent method for evaluating muscle injuries, assessing defense cell proliferation, and intracellular structure.

Thus, we have evaluated the benefits of 3-day IPC prior arthroscopy knee surgery on acute functional recovery and muscle damage.

METHODS: Nineteen volunteers (29.1 ± 9.4 yrs) were divided into 2 groups: Control, underwent knee surgery without prior intervention and IPC, submitted to 3-days IPC prior arthroscopy surgery. IPC intervention consisted of 4 cycles of 5-min occlusion (cuff pressure of 10 mmHg above occlusion pressure) while Control remained in rest for the same time. An assessment was conducted 24 hours after the surgical procedure to evaluate pain, edema, and range of motion. Muscle biopsy was collected at two different time points: at minute zero - after inflating the tourniquet - and at minute 75 after tourniquet inflation, in the vastus medialis obliquus muscle. A mixed model ANOVA, Student t-test and Effect size (ES) were carried out for moments and groups' comparisons

RESULTS: A higher thigh swallow ($p<0.01$) and higher knee extension ($p<0.051$) after surgery were found in IPC group. An observational muscle biopsy revealed lower edema and myofibrils degeneration and higher sarcomere organization in the IPC group.

CONCLUSION: A repeated IPC intervention may improve acute recovery of range of motion and reduce skeletal muscle damage after an elective arthroscopy knee surgery.

ESTIMATING THE OXYGEN COSTS OF THE INCREMENTAL SHUTTLE WALK TEST FROM A FOOT-POD POWER METER; CONCEPT EVALUATION TOWARDS CLINICAL APPLICATIONS

JONES, S., BURT, D., PHEASEY, C., BUCKLEY, J.

KEELE UNIVERSITY

INTRODUCTION: The Incremental Shuttle Walk Test (ISWT) is a recommended test of cardiorespiratory fitness for cardiopulmonary populations [1]. The accuracy of estimating oxygen uptake (VO2) during the ISWT is affected by the participants ability to match set paces. Wearable foot-pod power monitors may provide a more accurate means to derive estimates of VO2 . Benefits of more reliable and valid VO2. estimates could eliminate time needed for the requisite practice test of the ISWT. This study aimed to develop an equation to estimate VO2 from walking power measured by the Stryd-Power foot-pod (Boulder, Colorado).

METHODS: Fourteen healthy participants (31.6 +/-9.7 years) completed nine stages of the ISWT, in a counterbalanced order, over-ground (around cones) and continuously on a treadmill (Tmill). Data was collected up to the 9th stage of the ISWT, as stage 10 is the threshold for running. VO2 was measured continuously in both tests via a portable/wearable cardiopulmonary gas exchange monitor (Meta-Max 3B, Leipzig). Similarly walking power in was measured continuously via the Stryd-Power foot-pod.

RESULTS: Group mean Incremental Area Under the Curve (iAUC) for integrated VO2 x time was greater for the ISWT vs Tmill (167.4 +/-14.8 vs 153.2 +/-19.7 ml/kg; p = .003). There was no difference in iAUC walking power in ISWT vs Tmill (11.9 +/- 2.5 vs 11.6 +/- 2.0 Watts·mins; p = .267). ISWT and Tmill both demonstrated curvilinear VO2 (y) responses as a function of test stage/time (x), with these resulting equations: ISWT VO2 = 0.2069x2 - 0.1759x + 8.5048; Tmill VO2 = 0.1632x2 - 0.1887x + 8.631. Walking power displayed linear responses to incremental stages for both ISWT and Tmill test: ISWT Watts = 0.1775x + 0.1214; Tmill Watts = 0.1775x + 0.1214. The respective mean curvilinear regression equations to estimate VO2 from the Stryd-power monitor for ISWT and Tmill were: ISWT VO2 = 6.8439x2 – 3.0899x + 8.8856; TMill VO2 = 4.1162x2 – 0.6498x + 8.4621.

CONCLUSION: This study confirms it is possible to use a wearable foot-pod to assess changes in walking power during the ISWT. Corresponding measured VO2 during the ISWT over-ground around cones and on a Tmill provides a mathematical model to estimate VO2 from a foot-pod monitor that is now ready to be tested in cardio-pulmonary populations. The study also concurs with previous studies [2, 3] on the need for separate shuttle walking and Tmill regression equations to estimate VO2.

ASSOCIATION BETWEEN INTER-LIMB ASYMMETRY AND ENDURANCE RUNNING PERFORMANCE IN HEALTHY POPULATIONS: A SYSTEMATIC REVIEW

DHONDT, J., CHAPELLE, L., BISHOP, C., AERENHOUTS, D., DE PAUW, K., CLARYS, P., DHONDT, E.

VRIJE UNIVERSITEIT BRUSSEL

INTRODUCTION: The presence of inter-limb asymmetry in the human body has traditionally been perceived to be detrimental for athletic performance. However, a systematic review addressing and comprehensively assessing the association of asymmetry between the lower limbs and endurance running performance is currently lacking. Therefore, the main purpose of this systematic review was to examine the relationship between lower inter-limb asymmetry and running performance in healthy endurance runners. The secondary objective was to identify possible avenues for further research in this area.

METHODS: Pubmed, Web of Science and SPORTDiscus were systematically searched by two independent researchers for studies investigating the relationship between lower inter-limb asymmetry and (determinants of) running performance in healthy and injury-free endurance runners of any level. The quality of studies eligible for inclusion was assessed using the Downs and Black Quality Index Tool (Downs & Black, 1998).

RESULTS: Out of 4817 articles screened, 8 studies were included in this review. The quality score of the included research varied between 5/10 and 9/10. Except from one finding demonstrating a positive association between peak ankle dorsiflexion asymmetry and running performance, all other lower inter-limb asymmetry outcome measures were either negatively (N = 16) or not significantly (N = 30) associated with running performance.

CONCLUSION: A high heterogeneity across study methods and outcomes was apparent, making it difficult to draw a straightforward conclusion. Despite one study showing a positive relationship, the results demonstrate that some, but not all, metrics of functional, morphological, kinematic and kinetic inter-limb asymmetry are negatively or not associated with running performance. Thus, a more extensive high-quality body of research is essential to determine whether and to what extent asymmetry between the lower limbs could affect endurance running performance as well as to establish potential trade-off values for practitioners in developing training programs.

OP-SH20 Physical activity promotion and children

PHYSICAL LITERACY AND PHYSICAL ACTIVITY

KNISEL, E., BREMER, M., NALECZ, H., LAUDANSKA-KRZEMINSKA, I.

OTTO-VON-GUERICKE UNIVERSITY OF MAGDEBURG

Introduction

Physical literacy is important to understanding and promoting childrens participation in physical activity. Based on the concept of physical literacy by Whitehead (2019) the Canadian Assessment of Physical Literacy, second edition (CAPL-2;

Longmuir et al., 2018) for children 8-12 years old consists of two questionnaires to assess Knowledge and Understanding and Motivation and Confidence domains. The Daily Behaviour domain is assessed from one item of self-reported moderate-to-vigorous physical activity (MVPA) and step counts for one week. To measure the Physical Competence domain three physical tests are applied. An aim of our validation studies of the questionnaires of CAPL-2 in Poland and Germany was to analyse the relationship of self-reported MVPA and Motivation and Confidence and Knowledge and Understanding, respectively, and the total score.

Method

The total sample size of our validation studies was N=802 with n=470 Polish students (216 boys, 254 girls; mean age=11.10) and n=332 German students (160 boys, 172 girls; mean age=11.05). Correlation analysis of Pearsons r (Polish sample) and Spearmans rho (German sample) were performed. The correlation coefficients results were interpreted as less than 0.1 – negligible; 0,1 to 0.39 – weak, 0,4 to 0,69 – moderate, 0.7 to 0.89 – strong, 0.9 to 1 – very strong (Schober et al., 2018).

Results

Motivation and Confidence domain is weakly to moderately correlated with the subjective measured MVPA among German (r=0.31; p<0.01) and Polish (r=0.44; p<0.01) sample, respectively. In Poland the correlation of Knowledge and Understanding domain and MVPA is weak (r=0.16; p<0.01), in Germany no significant correlation (r=0.07) was found. In both countries the correlation of the total score and the MVPA is significant and weak in Germany (r=0.30) and moderate in Poland (r=0.43).

Discussion

Our results demonstrate that students with higher level of Motivation and Confidence reported to be more physically active. However, no such relationships were found with Knowledge and Understanding domain. Furthermore, we observed a relationship between physical literacy and physical activity. Future research in the area of physical literacy should examine to what extent the relationship of better knowledge of physical activity and higher level of motivation influence daily physical activity in the long run.

BASIC PATTERNS OF PHYSICAL DEVELOPMENT OF PRESCHOOL CHILDREN IN ECONOMICALLY DEVELOPED PROVINCES OF CHINA

HU, X., REN, X.

COLLEGE OF PHYSICAL EDUCATION AND HEALTH SCIENCE, ZHEJIANG NORMAL UNIVERSITY

Introduction

As a major component of physical health, physical fitness is considered an important indicator of child growth and development. Pre-school is the period of particularly rapid growth and physical development of children, which is characterized by intensive development the child's organism and dramatic changes in the functional system of activity, thereby promoting their motor ability. The objective of the present study was to investigate the status of physical fitness in children aged 3-6 years in economically developed provinces of China, in an attempt to explore the basic patterns.

Methods

A total of 800 preschoolers in four age groups of 3-6 years were recruited with 200 in each group. The inclusion of each physical fitness indicator was based on the Chinese Handbook of National Physical Fitness Measurement Standards (children's section). The outcomes of sit and reach, standing long jump, tennis ball throw, 10 m out-and-backs, beam walking, and two-foot hop were computed and statistically analyzed by a one-way analysis of variance (ANOVA).

Results

No significant differences were observed for sit and reach between the three age groups of 3, 4 and 5 years, but they were significantly different from the 6-year-old group ($p < 0.0001$), with the outcomes improved by approximately 3 cm. There were significant differences ($p < 0.0001$) between the groups for standing long jump, tennis ball throw, 10 m out-and-backs, beam walking, and two-foot hop. Improvement in the standing long jump decreased, with the mean values of 19 cm, 18 cm, 13 cm from ages 4 to 6. Improvement in the tennis ball throw was the greatest in age 5, with the mean values of 1.6 m compared to age 4. The greatest gains were made in the 10 m out-and-backs and two-foot hop in age 4, with the mean reduction of 2 s compared to age 3. The improvement in beam walking was essentially the same for each age group, with a mean reduction of 2.5 s.

Discussion

The findings revealed that the overall level of physical fitness of preschool children continues to gradually improve with age. The development of flexibility is significantly lower than that of other physical fitness indicators, while the develop-

ment of balance and strength is relatively faster. The motor cognition of preschoolers aged 3-6 years is in the state of enlightenment, and the motor cognition of different age groups determines the level of physical fitness development. Physical activity performed in the preschool years might be directly related to the development of physical fitness. Flexibility is a key area of concern for school-age children and requires targeted practice. Therefore, the guiding role of preschool education should be fully utilized to set up an appropriate amount of intriguing physical activity to stimulate their interest in exercise according to the pattern of physical development at different ages.

THE LACK OF SPORTS EXPERIENCES COULD BE A BARRIER TO ACHIEVING HIGH LEVELS OF MOTOR COMPETENCE AND FUNDAMENTAL MOTOR SKILLS IN SEVEN YEARS-OLD CHILDREN?

FONT-LLADÓ, R., LÓPEZ-ROS, V.1, JÓDAR-PORTAS, A.2, VASILEVA, F.2, HOMS, J.2,3, PRATS-PUIG, A.2,3

UNIVERSITAT DE GIRONA

INTRODUCTION. Motor development is described as a progressive process that occurs when an individual participates in a rich context with a variety of motor opportunities. Motor competence (MC) defines an individuals degree of proficient performance in a large range of motor skills. Proficiency barriers propose an "adequate" level of Fundamental Motor Skills (FMS) as a prerequisite for participation in sport-specific activities (1), to influence health (2). However, considering sport as a specific context with a broad range of motor opportunities, another hypothesis is possible. This study aimed at a) exploring the influence of sports experiences in MC and FMS levels in 7 years-old children, and b) assessing the impact of an Integrated Neuromuscular Training program (INT) in MC and FMS considering the baseline level of MC and FMS, and sport experiences in 7 years-old children.

METHODS. This randomized control trial recruited 228 children (y=7.45 ± 0.34). Group-based INT program in the warm-up (INT group, n=116) was compared with the group-based conventional warm-up (CON group, n=92) both over 24 PE lessons. Data were collected in 2 sessions (pre-post): Physical Activity (MVPA) with Actigrah 3GTX, IMC, sport experiences, MC, and FMS level using the CAMSA test (8). A multiple linear regression analysis was performed to identify predictor variables to MC and FMS, furthermore to MC and FMS improvements. Differences across groups (sex, IMC, and Sports experiences) were analyzed by independent T-test and ANOVA.

RESULTS. Adjusted by MVPA and sport modality, the amount of sports practice (ASP) is an independent predictor of 2-foot jumping and skipping, explaining 23,6%, and 5,7%, of its variability respectively. Also, ASP and IMC are associated with MC (28,7%), Sliding (11,2%) and 1-foot hopping (16%) explaining its variability. Finally, ASP and sex are associated with catching (11,5%), throwing (26,3%), and kicking (28,6%) explaining its variability. Interestingly, only ASP is associated positively. According to sport modality, sport-based-locomotive-skills practitioners showed faster than sport-based-manipulative-skills practitioners ($p<0.000$) and non-sport practitioners ($p=0.002$). In linear regressions analyses after adjusting for sex, IMC, and sport modality, ASP, INT interventions, and initial level of MC and FMS are associated with improvements of MC, sliding, catching, and throwing explaining 30,9%, 28,4%, 48,1% and 31% of its variability respectively, not in the other skills.

CONCLUSIONS. The amount of practice sport in 7-year-old children influenced mastery in MC and FMS patterns. MVPA and sport modality are not significant in this model. However, sports-based-locomotive-skills seem better to be faster, but not to master MC. The amount of practice sport, initial MC and FMS level, and INT intervention are good predictors of mastery MC and improved FMS levels in 7-year-old children.

AN EXAMINATION OF FACTORS RELATED TO STUDENTS' LEARNING STRATEGIES AND ATTITUDE OF PHYSICAL EDUCATION CLASS IN JUNIOR HIGH SCHOOL

YU, A.

HOKKAIDO UNIVERSITY

Introduction

In Japan, most activities in elementary and junior high schools are conducted in classrooms, students spend much of their time with teachers and classmates. Because they often take classes together, students' learning strategies and attitudes may change depending on how they perceive their teachers and classmates in their group. However, most of the studies on students' learning strategies and attitudes in physical education classes have focused on students' own consciousness, and there were few studies on how they perceive their group members. The purpose of this study was to clarify the effects of students' consciousness of norms and their perception of other students' norm consciousness and their perception of teachers' norm consciousness on their learning strategies and attitudes in physical education classes.

Methods

The subjects of the study were 548 students (254 boys and 294 girls), enrolled in two schools in Japan. The questionnaire survey was used to measure learning strategies, attitudes toward physical education classes, students' consciousness of norms, their perception of other students' norm consciousness and their perception of teachers' norm consciousness. Multiple regression analysis was conducted using students' consciousness of norms, their perception of other students' norm consciousness and their perception of teachers' norm consciousness as independent variables, and their learning

strategies and attitudes in physical education classes as dependent variables. Based on previous studies, have reported gender differences in how students perceive others, analyses were conducted separately for boys and girls.

Results & Discussion

Gender differences were found in the factors influencing learning strategies and attitudes toward physical education classes. First, in terms of learning strategies, boys showed the significant positive effect of only their consciousness of norms, while girls showed the significant positive effect of their consciousness of norms and their perception of other students' norm consciousness. Second, for the attitudes toward physical education classes, boys showed significant positive effects for their consciousness of norms and their perception of other students' norm consciousness, whereas girls showed no significant effects for any of the factors. Previous studies have reported that how perceive their teachers and classmates in their group influences own thinking and behavior, but based on the results of this study, it is possible that what is influenced by the perceptions of classmates, teachers, differs between boys and girls. Based on these findings, it can be inferred that different approaches are needed for genders if we are to consider changing learning strategies and attitudes in a positive direction.

DYSFUNCTIONAL EDUCATION AND MALTREATMENT OF YOUNG PEOPLE: A STUDY OF "BLACK PEDAGOGY"

SOOS, I., WHYTE, I., SZEKERES, D., NEMETH, ZS., BOROSAN, L., CSEPELA, Y., CSERNY, A., HAMAR, P.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

Introduction

"Black pedagogy" is a term that encompasses practices or behaviours identified in the pedagogical process that negatively affects the physical and mental health of young people (Hunyadine et al., 2006). This maltreatment can include physical, sexual, and mental abuse, or neglect. Any educational institution or sports club could, directly or indirectly, knowingly or unknowingly, promote black pedagogy, resulting in lasting negative consequences or feelings of grievance among young people. The aim of this study was to examine retrospectively cases of incidents and maltreatment recalled by university students from their time in primary or secondary schools.

Methods

A questionnaire was developed using data from a previous black pedagogy study (Hunyadine & Nadasi, 2014). Questions were included to identify the cause and categorisation of perceived black pedagogy incidents, the sexes and ages of perpetrators, the outcomes, and resolutions. Following ethical approval by the lead university's Sports Science Ethics Committee, university students studying sport (n=149, aged 21.6 years, s=5.0, 72.5% male, 24.8% female, 2.7% not identified) voluntarily responded to the questionnaire. Data was descriptively analysed by IBM SPSS v. 29 software package.

Results

The most often mentioned incidents were forceful behaviour or aggression by a sports coach or physical education teacher in order to enhance performance (21.5%), punishment for perceived disrespectful behaviour (11.1%), favouritism or discrimination (7.4%), lack of empathy (4%), and punishment for perceived laziness (3.4%). Issues of sexual abuse were reported by 2 respondents (1.3%).

The sex of perpetrators was identified as being predominantly male (67.1% male, 16.8% female, and 8.1% both male and female). Perpetrators were mostly classified as being middle aged with 34.9% being between 41-50 years of age (30.2% aged 51 years or over, 18.2% aged 40 years or younger, 16.8% of perpetrators ages were unspecified).

Victims informed their friends, classmates, or teammates (36.3%) or parents (32.2%), who provided them with support. Nevertheless, 20.1% never mentioned it to anybody. The incidents were resolved in one of three ways: nothing changed, nothing happened (46.3%), young people changed teacher or coach, or moved school/ sports club (23.5%), the issue was resolved in favour of the victims, e.g. apologies (16.1%). No information regarding resolutions were provided by 8.7% of respondents.

Conclusion

With 69.8% having either no resolution or the victims being forced to move, the findings call for a number of interventions. Guidelines identifying appropriate and inappropriate behaviour, policies and procedures must be developed for schools/organisations and those who work with young people, alongside reporting strategies and possible sanctions. Secondly, they must be disseminated through formal education and training, including to the pupils.

Invited Symposium

IS-MH12 Eccentric Exercise: Debunking Myths, Enhancing Rehabilitation, and Tailoring for Excellence

RE-EVALUATING CLASSIC BELIEFS ABOUT ECCENTRIC EXERCISE

LEPLEY, L.
UNIVERSITY OF MICHIGAN

The complexity of muscle atrophy following traumatic joint injury necessitates a therapeutic approach that targets the factors involved in muscle health and growth. Joint injuries, like anterior cruciate ligament (ACL) rupture, lead to an immediate disruption in neural signaling required for muscle activation. This disruption negatively affects muscle volume and quality, primarily due to the reduced ability to generate necessary action potentials to maintain muscle health. Exercise modalities that therefore rely on the patients neural drive to control contractions have proven ineffective after joint injury because achieving full and sustained muscle contractions is challenging. Lengthening contractions, also known as eccentric muscle actions, present an appealing alternative to shortening contractions as they have the capability to uniquely trigger the nervous system and signaling pathways that support tissue health and growth. Promising results have emerged from the use of eccentrically biased exercise prescriptions to enhance muscle recovery after injuries like ACL rupture. Various techniques, such as electromyography, neuroimaging, immunoblotting, and immunostaining, have shed light on the beneficial adaptations associated with eccentric exercise. Despite its growing acceptance as an exercise prescription, there is still reluctance within the clinical community due to longstanding associations of eccentric muscle actions with muscle injury. This dogma is due, in large part, to misinterpreted benchtop models that often involve extreme conditions that do not accurately represent the clinical scenario (i.e., the removal of the distal point of long-tendon from the bone for experimental purposes or animals that are exercised with the intent to cause injury). Through this lecture, Dr. Lepley aims to provide basic supporting evidence from the single fiber to the whole tissue level supporting the hypothesis that the inclusion of lengthening exercises in musculoskeletal rehabilitation can be a safe and effective exercise prescription for promoting muscle recovery. She will discuss how these adaptations are primarily driven by improvements in neural drive and responsive cellular signaling resulting from stretching and repetitive lengthening of activated muscles. ACL injury will be used as a model, and attendees will be encouraged to consider the responsible use of isolated lengthening exercises to address the various factors after joint injuries that contribute to the degradation of muscle tissue health and volume. Dr. Lepley will also direct therapists to a series of original clinical articles that provide protocols that can serve as guidelines for development.

ACCELERATING RECOVERY POST-ACLR WITH EARLY-STAGE ECCENTRIC CROSS-EDUCATION

ANDRUSHKO, J.
NORTHUMBRIA UNIVERSITY

Present anterior cruciate ligament reconstruction (ACLR) rehabilitation protocols typically postpone dynamic open-chain strength training exercises until 3 to 4 weeks post-surgery. Although this delay minimizes post-operative complications by allowing the graft to heal, it also dampens the recovery rate, leading to decreased quadriceps muscle strength, size, and altered neuromuscular function in both limbs. These changes, when left unaddressed, enhance the risk of developing osteoarthritis. Since quadriceps strength is protective against the development of osteoarthritis, strength training to enhance knee extensors muscle strength is a critical aspect of the rehabilitation process. In this context, the first 3 to 4 weeks post-ACLR, with current standard rehabilitation protocols, represent a pivotal yet underutilized period. This window of missed opportunity offers room for enhanced recovery strategies. Cross-education is a concept where training one side of the body benefits the opposite, untrained side. These protocols can potentially counterbalance the muscle size and strength declines stemming from disuse during this period of recovery. However, the mode of exercise matters, as work has consistently shown that eccentric cross-education promotes nearly 2 times greater strength gains and more robust neural recovery than concentric or isometric cross-education protocols. Despite its potential, eccentric cross-education hasnt been widely adopted in clinical settings due to an incomplete understanding of the mechanisms behind it. Some clinicians also fear it may exaggerate limb strength and size asymmetries; measures often monitored during ACLR rehabilitation. Despite these reservations, neglecting strength preservation in the early post-surgery phase may be shortsighted given the risks associated with weak knee extensors. This lecture emphasizes the critical role of muscular strength for preventing future knee injuries and the development of osteoarthritis. We will review the literature investigating the use of cross-education to offset disuse related declines in muscular strength and size, and introduce the potential mechanisms of cross-education in the context of developing an optimized adjunct eccentric cross-education protocol. This approach is designed to enhance and complement standard rehabilitation practices to preserve muscle strength, and accelerate recovery of the reconstructed limb during the early-stages post-ACLR.

PRACTICAL INTERVENTIONS UTILIZING ECCENTRIC EXERCISE FOR ELITE ATHLETES: MID TO LATE STAGE REHABILITATION AFTER ACL RECONSTRUCTION

LORENZ, D.
LAWRENCE MEMORIAL HOSPITAL / ORTHOKANSAS

Successful athletic performance in field and court sport athletes is largely predicated on the ability to decelerate and accelerate at high rates of speed. Thus, appropriate training in both rehabilitation and strength and conditioning settings maximizes an athlete's ability to put maximal force into the ground while also minimizing ground contact time. Since a substantial number of field and court sport athletes regularly involve themselves in high-velocity acceleration and deceleration, their aptitude for slowing down and altering their direction is intricately tied to their proficiency in managing eccentric movements before transitioning into concentric acceleration. In instances where individuals exhibit inadequate knee shock absorption and an elevated level of knee stiffness upon landing, particularly as seen in those with compromised quadriceps function, such as in the case of anterior cruciate ligament reconstruction (ACLR), it becomes imperative for clinicians to prioritize the inclusion of eccentric exercises as a pivotal component of the rehabilitation plan. The force-velocity curve illustrates the dynamic relationship between muscle force and contraction velocity. On the concentric side of this curve, we observe that the highest forces are generated when the velocity is zero, and as velocity increases, force diminishes. In contrast, when we shift our focus to the eccentric side of the force-velocity curve, where the muscle lengthens while still producing force, a remarkable characteristic emerges: the muscle can maintain relatively high-tension levels even at higher velocities. This unique attribute means that with eccentric muscle actions, the muscle exhibits the ability to generate both high force and high velocity actions. Consequently, through appropriate training strategies, athletes can aim to achieve this dual objective. The focus of this lecture is to provide attendees with practical interventions clinically throughout the rehabilitation timeline that focus on the physical qualities of athletic performance. Interventions will focus on using eccentric exercise to produce maximum force and gradually progress to high force, high velocity decelerations to match the demands for returning to sport. A secondary objective is to provide specific program design recommendations in regard to loading parameters as well as sets and repetitions performed to achieve the training objectives.

Invited Symposium

IS-AP04 Science of Feet and Footwear

MUSCULOSKELETAL DEVELOPMENT AND MOTOR SKILLS OF CHILDREN AND ADOLESCENTS ARE INFLUENCED BY GROWING UP BAREFOOT OR SHOD

ZECH, A.
UNIVERSITY OF JENA

Improvements of motor skills are basic processes of growth, maturation and development during childhood and adolescence. They are not only a direct consequence of learning processes but are also influenced by interactions between regular external (environmental) and internal (e.g. neuromuscular) factors. These include anthropometrical and muscular characteristics of the foot. It has been shown that different structural foot types such as high and low arches are associated with the performance of basic motor skills such as balancing, jumping or sprinting. Since the foot morphology differs between barefoot and shod populations, footwear habits have long been discussed to play an important role for motor learning and motor control. Evidence exists that compared to shod conditions, barefoot situations directly change gait biomechanics, postural control and jumping movements in children and adults. Individuals growing up barefoot also tend to have wider feet with a higher arch and smaller hallux angles. This emphasizes the hypothesis that the development of basic motor skills during childhood and adolescence partly depends on the amount of physical activity under barefoot conditions. A comparison of motor skills between habitually barefoot and shod individuals in the same setting is difficult, since barefoot habits seem to be influenced by sociocultural and regional factors. Individuals in western countries are used to wear shoes during almost all outdoor activities whereas especially children in some countries in the southern continents are often seen barefoot. The potential interaction between growing up barefoot or shod and performance in basic motor competencies during the different stages of childhood, adolescence and into adulthood will be discussed.

HOW THE FOOTWEAR-SURFACE ENVIRONMENT ALTERS MOVEMENT STRATEGIES AND MUSCLE RECRUITMENT IN RUNNERS

ODDY, C.
LEEDS BECKETT UNIVERSITY

Unlike other primates, the human foot has an arch capable of both stiffness and deformation to varying degrees dependent on the terrain. It can store and release energy via springs (ligaments, aponeurosis, tendons) in order to make efficient use of muscle work during running. During running, muscles are continuously operating via both feedforward (in anticipation via vision) and feedback (in response via sensory physiology) mechanisms. Muscle responses will perhaps be most evident via kinematic changes at the major joints and the extent of muscle pre-activation in anticipation of the expected ground contact. In many runners, acutely and at submaximal speeds, barefoot running results in a reduction in stride

length and increased plantar and knee flexion. Runners who are habitually barefoot demonstrate lower loading rates (force) compared with their shod counterparts. This is thought to be due to the optimisation of the limb position for ground contact and the pre-activation of muscles in anticipation. Previously shod runners who respond to a barefoot running intervention demonstrate increased biceps femoris and gluteus medius pre-activation, and decreased rectus femoris muscle activity between testing periods. The kinematic changes evident in some runners who transition to barefoot running seem to be similar to that experienced when running on an irregular surface. On an irregular surface, the knee and ankle appear to move in synchrony whereby the ankle stiffens and has a reduced rearfoot action. A spring-like ankle combined with an increase in knee flexion may increase impact attenuation. The task (barefoot running) and environmental (irregular surface) constraints may enhance the coordinated action of the spring-like function of the foot and the energy absorbing capacity of more proximal muscles. Subtle differences in ground deformation and subsequent foot placement will challenge the biotensegrity of foot structures and the plantar cutaneous nerve receptors to respond with variations of tensioning and stiffening. These variations facilitate a consistent outcome (running) using different patterns of joint relations, a concept known as dynamical systems. Lieberman and colleagues reported 72% of barefoot runners use a varied foot strike pattern compared with just 32% of shod runners. All runners used a more varied foot strike pattern on a softer surface. This lecture will aim to explore how the footwear we use and the surface we run on changes our biomechanics via altered muscle work.

THE ROLE OF FOOTWEAR IN ATHLETIC INJURY

FRANCIS, P.

SOUTHEAST TECHNOLOGICAL UNIVERSITY

For a relatively simple activity with numerous health benefits, the incidence of running injury is high compared to other aerobic activities. The debate amongst scientists about whether footwear plays a role in running injury and whether conventional, minimalist, or maximalist footwear is optimal toward injury prevention has moved on. Despite the high incidence of injury, there are many runners who do not get injured including those that run in conventional running shoes and with an infamous rear-foot strike. Indeed, most world championship marathon runners wear cushioned running shoes and use a rear-foot strike. However, in runners who do get injured, the top 5 injuries occur to non-contractile tissues (patellofemoral pain, shin splints, plantar fasciitis, achilles tendinopathy, iliotibial band), ill-equipped to absorb impact forces. There is a growing body of evidence which suggests the movement strategies used by these athletes are injurious in nature and are contributed to by footwear-surface interactions. As described in the introduction for this session, the human foot has undergone rapid changes in its footwear and surface environment in a very short space of time relative to human evolutionary history. Modern footwear is known to weaken the intrinsic muscles of the feet and encourage 'heavier' running mechanics (rear-foot strike) on what are now largely unyielding surfaces (roads, pavements, running tracks). Increasingly, scientists are beginning to view plantar fasciitis (chronic heel pain) as a mismatch disease, in other words a disease directly related to changes in the footwear-surface environments. This lecture will aim to provide insight into the role of footwear in running injury and make suggestions for how to run our way out of it.

OP-AP01 Machine Learning

A POPULATION-BASED STUDY EXPLORING BIOCHEMICAL PHENOTYPES AND THEIR RELATIONSHIP WITH PHYSICAL FUNCTION, HEALTH OUTCOMES AND MORTALITY IN OLDER ADULTS USING UNSUPERVISED MACHINE LEARNING APPROACH.

GONZÁLEZ MARTOS, R., RODRÍGUEZ-GÓMEZ, I., RAMÍREZ-CASTILLEJO, C., GALEANO, J., ARA, I, ALEGRE, L.M., RODRÍGUEZ-MAÑAS, L., GARCÍA-GARCÍA, F.J., GUADALUPE-GRAU, A.

UNIVERSIDAD POLITÉCNICA DE MADRID; UNIVERSITY OF CASTILLA-LA MANCHA

INTRODUCTION: Aging is associated with health issues leading to functional decline and disability. Identifying key factors (biochemical, physical, or social) for successful aging is crucial for resource efficiency [1]. Using unsupervised clustering analysis on routine laboratory test data, we aim to uncover biochemical phenotypes in the spectrum of old age. This approach may enhance understanding of mechanisms influencing healthy aging. We also intend to explore associations between these phenotypes and key health outcomes, including mortality [2].

METHODS: A final sample of n=1491 participants (65 to 99 years old, 57.7% women), from the Toledo Study for Healthy Aging (TSHA), was included. Hierarchical and k-means cluster analyses (Orange software) incorporated 39 variables related to white and red blood cells, and renal, liver lipid, and glucose metabolism. Health outcomes included body composition (DXA), physical functionality (SPPB test), physical activity (PASE questionnaire), disability (Katz questionnaire), frailty (FTS-5 test), comorbidity (medical history), and 12-year mortality (Spanish National Mortality Database). The associations between cluster membership and health outcomes and mortality hazard ratios (HR) were analyzed through general linear models (ANCOVA, SPSS software) and Cox regression (STATA software) respectively, including sex, age, and socioeconomic status as covariates.

RESULTS: Three different clusters were identified: Cluster 1 (41.8%, Healthy), all biochemical values within the normal range, taken as reference for statistical analysis; Cluster 2 (44.5%, Metabolic), characterized by high but sub-clinically relevant

levels of glucose, triglycerides, HOMA, and liver enzymes; and Cluster 3 (13.7%, Red Blood Cells), defined by lower levels of hematocrit, hemoglobin, and red blood cells. Our findings revealed that Cluster 2 (metabolic) showed a significantly higher BMI in men (28.70±0.21 vs. 27.46±0.35 Kg/m2) and women (31.01±0.35 vs. 29.61±0.26 Kg/m2), and a higher risk of death in women (HR=1.50; 95%CI= (1.08; 2.08)) respect to the healthy cluster. Cluster 3 (Red Blood Cells) participants were older (77.8±0.4 vs. 74.5±0.2 yrs.), and men were less physically active (PASE score: 57.46±6.03 vs 69.40±4.41) and showed worse physical functionality with less gait speed (0.85±0.04 vs 0.94±0.03 m/s) than healthy cluster. They were also less independent in their daily activities with a significantly lower Katz index in both sexes (men: 5.46±0.08 vs. 5.82±0.06; women: 5.56±0.07 vs. 5.77±0.04). Significant findings ($p<0.05$) were observed for all mentioned values.

CONCLUSION: Our findings suggest that a biochemical phenotype characterized by impaired red blood cell function is associated with a decreased health-related quality of life, whereas impaired glucose and lipid metabolism is associated with a higher risk of death. This information could be helpful to develop exercise-based interventions oriented to healthy aging.

PREDICTING VERTICAL GROUND REACTION FORCE CHARACTERISTICS AND CONTACT TIME IN RUNNING WITH MACHINE LEARNING

BOGAERT, S., DAVIS, J., VANWANSEELE, B.

KU LEUVEN

INTRODUCTION: Running poses a high risk of developing running-related injuries [1]. The majority of RRIs are the result of an imbalance between the cumulative musculoskeletal load and a person's load capacity [2, 3]. Therefore, measuring and monitoring the musculoskeletal load during running is essential for the prevention of RRIs. A general estimate of whole-body biomechanical load can be inferred from ground reaction forces (GRFs). Unfortunately, GRF typically can only be measured in a controlled environment, which hinders its wider applicability. Applying machine-learning algorithms to wearables-collected data enables runners to monitor GRF characteristics in various settings [4], extending beyond the confines of the laboratory. Our study presents and evaluates a machine-learning method to predict contact time, active peak, impact peak, and impulse of the vertical GRF (vGRF) during running from 3D sacral acceleration.

METHODS: Twenty-seven subjects with varying running experience ran on an instrumented treadmill (Motek Medical BV) at various speeds for 150 seconds at each speed. The instrumented treadmill measured ground reaction forces, and a sensor (Xsens Technologies, Movella) on the lower back captured 3D acceleration. In total, we obtained 50072 steps of which 28078 steps had an impact peak. Subject characteristics, general statistical, and domain-specific features were extracted from the 3D acceleration signal for each step.

We used a Lasso (Least Absolute Shrinkage and Selection Operator) model to predict the characteristics of the vGRF. We partitioned the data into a training (23 subjects) and test (4 subjects) set. To select the hyperparameter settings, we conducted a leave-one-subject-out cross-validation on the training set. We compared the performance of our approach to the methods outlined in the work of Alcantara et al. [4] regarding active peak, contact time, and impulse; Verheul et al. [5] for the impact peak using a single-sensor setting.

RESULTS: The developed models for predicting active peak, impact peak, impulse, and contact time had a root-mean-squared error of 0.084 body weight (BW), 0.221 BW, 0.005 BW.s, and 0.008 seconds, respectively. Our models outperform the corresponding comparison method from the literature on our data sets by respectively 0.061 BW, 0.054 BW, 0.0032 BW.s, and 0.0006 seconds.

CONCLUSION: These results indicate the feasibility of our approach for monitoring selected factors associated with running-related injuries outside the laboratory with a single sensor.

MACHINE LEARNING IN MOTION: ENHANCING MOVEMENT COMPETENCE ASSESSMENTS USING WEARABLES AND NOVEL DATA SIMULATION TECHNIQUES

SWAIN, T.1, MCNARRY, M.1, BARNES, C.1, SIMPSON, C.2, THOM, G.3, RYAN, L.1, MACKINTOSH, K.1

1. SWANSEA UNIVERSITY, 2. DUNDEE AND ANGUS COLLEGE, 3. INDEPENDENT RESEARCHER, DUNDEE, UNITED KINGDOM

INTRODUCTION: Assessing movement quality in real-world settings remains challenging. Indeed, previous research has questioned the reliability and accuracy of directly quantifying motion characteristics (e.g. range of motion) using wearables (1, 2). Whilst machine-learning classification techniques offer promising alternatives, they are often limited by a reliance on small sample sizes, thereby impacting robustness and real-world transferability. The aims of this study were therefore two-fold: i) to generate a machine-learning algorithm to classify foundational motor skill competence, using the

bodyweight squat as a representative movement; and ii) to develop a novel data simulation method to artificially boost the sample size and enhance classification accuracy.

METHODS: Twenty-three participants (28.1 ± 7.3 years; 17 males) performed three sets of 10 repetitions of squats. Data were captured using three Polar Verity Sense magnetic, angular rate, and gravity (MARG) sensors on the chest and both ankles. Three United Kingdom Strength & Conditioning Association accredited coaches classified each repetition as 'good', 'average', or 'poor', based on pre-determined movement criteria, with the modal score for each repetition used in data labelling. To expand and balance the dataset, original data were augmented with simulated data using Weibull distributions or Gaussian mixture models depending on the feature frequency distributions of the most informative features. A support vector machine (SVM) ensemble with a modal voting system was developed to classify squats with raw, then augmented raw and simulated data, for a comparative analysis.

RESULTS: Using only the original data for training, overall SVM ensemble classification accuracy using a hold-out dataset was 40%. However, the model yielded 0% accuracy for the repetitions labelled as 'good' due to dataset imbalance. Data-boosting improved sensitivity, increasing 'good' accuracy to >95%. However, overall accuracy did not improve due to large 'average' class inaccuracies (10%).

CONCLUSION: This study introduces a novel data-simulation method for improving movement classification by addressing imbalances often inherent in small datasets. Data-boosting was effective, improving sensitivity and accuracy for 'good' and 'poor' squat repetitions, even with small training datasets. However, overall accuracy did not improve due to classification issues in the 'average ' category. This underlines the challenges of using subjective scoring as the standard for algorithm training. Recognising the limitations of the current dataset, future research should refine data-labelling methods and seek larger, more balanced datasets to mitigate intermediate class ambiguity and further the pursuit of practical application.

BEYOND PLAYING POSITIONS: A NEW APPROACH TO CATEGORIZE SOCCER PLAYERS BASED ON MACHINE LEARNING

DE HAAN, M., VAN DER ZWAARD, S., SANDERS, J., BEEK, P., JASPERS, R.

VU AMSTERDAM

INTRODUCTION: It is unknown if categorizing soccer players by playing position is useful from a physiological perspective. This study examined sprint, endurance, and match-specific running performance of players, assessed alignment of match-specific running performance with playing positions, and evaluated the potential of unsupervised machine learning for identification of players with similar match-specific running profiles.

METHODS: Forty elite male soccer players had match-specific running data collected over two seasons, with 31 undergoing exercise testing, consisting of a 20-meter sprint and a treadmill test to measure maximal oxygen uptake. k-means clustering identified subgroups based on players' match-specific running performance. Differences in sprint, endurance, and match-specific running were compared between playing positions and between clusters. Both grouping methods were tested for their ability to identify subgroups with similar total distance (TD), low (LIR), moderate (MIR), high intensity running (HIR) and sprint distance in matches.

RESULTS: Match-specific running performance differed between playing positions, although notable variation was observed per playing position. Clustering based on match-specific running performance revealed less variance within groups (TD: $P = 0.049$, LIR: $P = 0.032$, HIR: $P = 0.033$) and larger standardized differences between groups (LIR: $P = 0.037$, MIR: $P = 0.041$, HIR: $P = 0.035$, Sprint: $P = 0.018$) compared to grouping by playing position. Moreover, 20-m sprint speed differed between the sprint and high intensity endurance cluster (25.22 vs 23.75, $P = 0.012$), but not between playing positions.

CONCLUSION: Utilizing unsupervised machine learning to group soccer players based on match-specific running performance enhances the identification of player groups with distinct physical profiles. This data-driven approach supports performance evaluation and enables training optimization towards groups of players with similar match-specific running performance.

TRIPLE-E PRINCIPLE FACILITATES BUILDING THE SOTA MACHINE LEARNING MODELS FOR ASSESSING ENERGY EXPENDITURE IN DANCE

TAO, K., MENG, K., GAO, B., QIU, J.

BEIJING SPORT UNIVERSITY

INTRODUCTION: Dance, as a widely practiced physical activity worldwide, encompasses diverse styles and tempos, making it challenging to accurately assess energy expenditure. Traditional methods rely on empirical formulas embedded in ActiGraph accelerometers, calculating vector magnitude counts per minute to gauge dance intensity. However, these formulas often lead to significant bias in estimating energy expenditure. To address this issue, multiple wearable sensors and accelerometers have been utilized to reduce prediction bias. Nevertheless, this approach increases the complexity of energy expenditure models and impacts participants flexibility during dance. This study introduces the Triple-E principle: effectiveness, efficiency, and extension. By adhering to this criterion, we developed state-of-the-art (SOTA) machine learn-

ing models to assess energy consumption during dance with the highest accuracy, minimal complexity, and optimal suitability.

METHODS: We enrolled 250 participants (mean age ±SD: 63.0 ±6.0 years) who engaged in one of three dance styles (ballroom, aerobic, square). Before the experiment, they completed a survey on anthropometric measures and exercise habits, underwent body composition exams, and wore CORTEX MetaMax 3B gas analyzers and ActiGraph wGT3X-BT accelerometers on five body sites. Ballroom dancers had two 10-minute dance sessions followed by a 10-minute rest. Aerobic dancers had one 20-minute session followed by a 10-minute rest. Square dancers had a 10-minute intense dance, a 10-minute soft dance, and a 10-minute rest. Participants rated perceived exertion using the RPE scale after 1-1.5 hours. After data cleaning, we obtained 311 physiological signal and 1555 acceleration count sequences.

RESULTS: Empirical formulas inaccurately assessed dance energy expenditure, with MAPE exceeding 50% and RMSE surpassing 3.23. We developed a bidirectional stepwise regression model, achieving a 0.73 average goodness-of-fit, exploring optimal accelerometer sites for Effectiveness and Efficiency. Features extracted from raw data showed varying CCC: 0.37 (waist), 0.89 (left ankle), 0.94 (right ankle), 0.78 (left wrist), and 0.80 (right wrist). A random forest regression model minimized errors to 5% (MAPE) and 0.33 (RMSE) when incorporating all site data. Wrist accelerometers and heart rate sufficed for energy expenditure estimation, with RMSE values of 0.35 and 0.36, respectively, indicating a trade-off between effectiveness and efficiency. A neural network pipeline, based on extension, automatically assessed energy expenditure, yielding R-squared values of 0.842, F1-score of 0.709, and recall of 0.774.

CONCLUSION: This study, to our knowledge, is the first to systematically assess energy expenditure in dance. Our contributions are twofold: introducing the Triple-E principle to regulate model aspects, and developing SOTA machine learning models for optimal sensor selection and accurate energy expenditure estimation.

Oral Presentations

OP-BM02 Motor Learning and Motor Control

FACILITATION OF CORTICOSPINAL EXCITABILITY DURING RECALLING AUTOBIOGRAPHICAL FEAR MEMORIES

MASHIKI, Y., KANEKO, N., KATO, T., YAMASAKI, D., TAKAHASHI, R., NAKAZAWA, K.
THE UNIVERSITY OF TOKYO

INTRODUCTION: Emotions significantly influence sports performance via modulation of motor control. A previous study indicated that negative autobiographical memories increase corticospinal excitability (CSE), which plays a crucial role in motor control [1]. However, we need to deal with various emotions, such as happiness, sadness, fear, and anger. Therefore, it is essential to explore the effect of discrete emotions for a better understanding of the relationship between emotions and motor control. Furthermore, it may provide valuable insight into improving responsiveness to various situations during sports performance by identifying the muscles in which CSE is likely to be modulated by emotions. Thus, this study aimed to investigate: (1) the modulation of CSE by discrete autobiographical emotional memories and (2) the muscle-specificity of CSE modulation in response to emotions.

METHODS: Sixteen healthy individuals (22–30 years old) participated in this study. Participants were seated on a chair. Electromyographic activity was recorded from the flexor carpi radialis (FCR), extensor carpi radialis (ECR), first dorsal interosseous (FDI), and abductor pollicis brevis (APB) muscles. CSE was evaluated by motor-evoked potential (MEP) amplitudes which were elicited by transcranial magnetic stimulation (TMS) to the primary motor cortex. Initially, participants were asked to write down situations in which they had experienced happiness, sadness, fear, and anger. For the neutral condition, participants were asked to describe their typical morning routine. We recorded 12 MEPs as they recalled the written situations for each emotion. MEP amplitudes during the recall of happiness, sadness, fear, and anger were normalized to the MEP amplitudes in the neutral condition. A statistical analysis was conducted using a two-way analysis of variance (ANOVA) with aligned rank transform. The ANOVA included two factors: 4 muscles and 5 emotions. Contrast tests were used as subsequent post-hoc tests. The level of significance was set to $p < 0.05$.

RESULTS: The two-way ANOVA showed a significant main effect for emotions ($p = 0.004$), but not for muscles ($p = 0.183$) and the interaction between muscles and emotions ($p = 0.502$). Subsequent post-hoc tests on emotions showed that the fear emotion significantly increased MEP amplitudes more than the neutral condition ($p = 0.001$, + 39.3%). On the other hand, there were no significant differences between any of the other emotions ($p > 0.05$).

CONCLUSION: Our results indicated that although no significant difference in MEP amplitudes was found between upper-limb muscles, the recall of autobiographical fear memories significantly increased MEP amplitudes. These suggest that the fear memories facilitate CSE and that this facilitation is non-specific to upper-limb muscles. Our finding enhances our comprehension of the interplay between emotions and motor control.

DECODING CORTICAL BIOMARKERS IN PARKINSONS DISEASE DURING OVERGROUND WALKING

PESKAR, M., GRAMANN, K., KALC, M., MILADINOVIC, A., MANGANOTTI, P., MARUŠIC, U.
SCIENCE AND RESEARCH CENTRE KOPER

Although highly automated, human gait is dependent on cortical resources and can be observed in spectral features such as sustained beta band (18-30Hz) desynchronization and gait-phase dependent modulation in the low gamma-band (24–40 Hz) recorded over central sensorimotor cortices. Contrary, Parkinson's disease (PD) is characterized by beta-band hypersynchrony which is positively associated with the symptoms of bradykinesia. However, this cortical phenomenon has never been noninvasively investigated in ecologically valid conditions during unrestricted overground walking and concurrent performance of a cognitive task. This study aimed to elucidate the mechanisms subserving full-body movement execution in conditions where attentional resources are simultaneously allocated to both cognitive and motor tasks mimicking real-life scenarios in PD patients. Sixteen early on-medication PD patients (aged M = 62.75 ± 5.9 years; 8 women) and 16 healthy controls (HC; aged M = 64.1 ± 6.5 years; 8 women) performed a self-paced overground walking task in a wide (80 cm) and narrow (40 cm) lanes both as single-task conditions (STwide, STnarrow) and with a secondary visual discrimination task as dual-task conditions (DTwide, DTnarrow). A mobile 128-channel EEG and full-body kinematics were recorded to compute gait-phase-dependent spectral modulation at the Cz electrode. Nonparametric cluster-based permutation testing correcting for multiple comparisons across all time-frequency space was used (1000 iteration, $\alpha \leq .05$). We observed faster walking speed for HC versus PD patients ($F(1, 30)=8.10$, $p=.008$) and for ST as opposed to DT conditions ($F(1, 30)=41.61$, $p<.001$). No significantly different clusters of cortical signatures would discriminate PD patients and HC or wide and narrow lane walking conditions. However, PD patients demonstrated greater synchronization in the beta and low gamma activity in both DT conditions compared to their respective ST variants. The differences were observed in the phase of gait following the heel strikes indicating preparation for shifting the weight to a single leg. The effect was more pronounced in the narrow walk conditions. The PD patients exhibit similar cortical signatures to HC during overground walking but seem to become prone to the cortical signature related to movement inefficiency upon performing cognitive-motor dual-tasking. In PD patients but not HC a secondary cognitive task evoked a gait-phase-locked synchronization in the high spectral frequencies, which could suggest the limited availability of cognitive resources at that particular time during the gait phase while the attention had to be continuously divided between the two tasks. These results indicate that movement execution in PD could be impeded by increasing the load on the cognitive systems. These outcomes provide valuable insights into mechanisms of simple real-life cognitive-motor dual-tasking in PD and can inform intervention and fall prevention strategies.

FATIGUE-RELATED INCREASES IN ALPHA BAND COMMON SYNAPTIC INPUT IS EXPLANATORY OF ALTERATIONS IN THE STRUCTURE OF LOWER-FREQUENCY OSCILLATIONS IN KNEE EXTENSOR TORQUE.

FENNELL, C., MAUGER, A., HOPKER, J.
UNIVERSITY OF KENT

INTRODUCTION: Torque complexity (the torque signal's nonlinear temporal and spatial structure) is indicative of the neuromuscular system's ability to meet the imposed motor task, and knee extensor (KE) torque complexity has been shown to decline with fatigue (1). However, the mechanisms underlying the fatigue-induced changes in complexity are yet to be fully elucidated. It has previously been demonstrated that common synaptic inputs to the motoneuron pool, estimated by intramuscle coherence, largely determine the structure of oscillations in the torque signal (2). This study investigated whether the proportion of common synaptic input to the vastus lateralis muscle (VL) could explain the effect of fatigue on KE torque complexity.

METHODS: Fifty-seven participants completed three fresh 20 s isometric KE contractions at 20% MVC, followed by a series of repeated 3 s isometric KE contractions at 60% MVC to task failure. Immediately after failure a 20 s isometric KE contraction at 20% MVC was performed. High-density surface EMG signals were recorded from the VL during all 20% MVCs and decomposed into individual motor unit (MU) spike trains. Thirty-seven participants provided enough MUs (>6) during all 20% MVCs for coherence analysis, as such only these participants data were analysed. Intra-muscle coherence was estimated from the MU data. KE torque variability and complexity was assessed using the coefficient of variation of torque (CVT) and multiscale sample entropy (MSE; across 28 coarse-grained scales) respectively.

RESULTS: The MSE analysis revealed a condition (fresh vs. fatigue) by coarse-grained scale interaction (i.e., a MSE curve cross-over; $P<0.001$); the fatigued 20% MVCs presented with a significantly lower sample entropy (SampEn; $P<0.05$) at shorter scales (<7 scales) but a significantly higher SampEn ($P<0.05$) at longer scales (>13 scales) when compared to the fresh 20% MVCs. Alpha coherence (5-15Hz) was significantly higher after task failure ($P=0.001$; fresh=1.30±0.09 vs. fatigued=1.43±0.22). The difference in Alpha coherence from fresh to fatigue was predictive of the difference in SampEn at scales 10 to 28 (all $P<0.05$; $R2=0.11$-0.19). Alpha coherence was also predictive of SampEn calculated at coarse-grained scales 7 to 28 during fresh (all $P<0.05$; $r=0.34$-0.60; $R2=0.12$-0.36) and fatigued (all $P<0.05$; $r=0.34$-0.52; $R2=0.11$-0.27) 20% MVCs. Fatigue resulted in a significantly higher CVT ($P<0.001$). The increase in alpha coherence with fatigue was predictive of the decline in the CVT ($P<0.001$; $r=0.56$; $R2=0.31$).

CONCLUSION: The MSE curve cross-over captures a fatigue-related change in torque regularity at the different scales, suggestive of an alteration in structure across the oscillatory frequencies present within the torque signal. Common synaptic input in the alpha band may be able to explain some of the fatigue-related alterations in the structure of lower-frequency oscillations of the KE torque signals.

LONG-TERM DEVELOPMENT OF A MOTOR MEMORY

NIETSCHMANN, P., FRANKLIN, S., PAPADOPOULOU, T., FRANKLIN, D.W.

TECHNICAL UNIVERSITY OF MUNICH

INTRODUCTION: Humans exhibit remarkable abilities in learning motor skills. While motor performance continues to improve with practice, even after years of learning[1], most studies only examine the learning of novel dynamics over several hundred trials[2 3]. That is, most of our understanding of the parameters and characteristics of motor learning rely on studies that examine only the early adaptation processes. While some studies of complex task adaptation have examined thousands of trials, the adaptation to a single velocity-dependent force field is usually considered to be complete within a few hundred movements[2 3]. Here we investigate motor adaptation to a single novel force field with over seven thousand trials and multiple weeks of training, to uncover the process of human motor learning.

METHODS: Ten right-handed participants performed training sessions once every week for eight consecutive weeks, with a follow-up session 15 weeks later to assess retention. Participants performed forward reaching movements with their right hand using a robotic manipulandum in a velocity dependent curl force field. Throughout the sessions we probed the adaptation process by measuring the decay, spontaneous recovery, retention, angular generalization, and transfer of the motor memory to the opposite limb.

RESULTS: Participants adapted quickly to the dynamics, showing a fast reduction in kinematic error and a rapid increase in predictive force compensation within the first session. Interestingly, we find continuous adaptation over the subsequent sessions. Moreover, there is strong retention of the predictive forces between sessions, increasing gradually until the fifth session. We observe a strong increase in spontaneous recovery between the first and seventh session, indicating a stronger motor memory, but little change in the decay rates over the training weeks. Despite extensive training, we found no evidence of transfer to the left hand. However, while generalization to adjacent reaching directions was stable across training weeks, we did find a slight narrowing of the Gaussian-like angular generalization with practice, suggesting a slight fine tuning of the spatial properties of the motor memory. Finally, even after 15 weeks without practice, participants immediately exhibited similar levels of predictive adaptation to the dynamics.

CONCLUSION: Our results show that learning continuously progressed over time, creating a stable motor memory that is retained for prolonged periods without task exposure. Notably, while predictive adaptation developed over time, other aspects, such as the decay rate, remained relatively unaffected during our training period. Our research highlights motor memory formation and durability and could inform training strategies aimed at developing motor skills or advancing rehabilitation.

EFFECT OF A FOUR-WEEK TRAINING WITH UNSTABLE BOARDS ON POSTURAL CONTROL MECHANISMS

RIZZATO, A., FAGGIAN, S., PAOLI, A., BOZZATO, M., MARCOLIN, G.

UNIVERSITÀ OF PADOVA

INTRODUCTION: Understanding the postural control mechanisms in dynamic balance training is warranted. We primarily aimed to study whether a four-week training with unstable boards could influence a transfer of balance ability to (i) a more challenging task and (ii) an untrained balance task (i.e., unexpected perturbation of the base of support). Moreover, we aimed to understand, through a non-linear center of pressure (CoP) analysis (i.e., Sample Entropy), whether a shift from voluntary to automatic postural mechanisms could occur in trained and untrained balance tasks.

METHODS: Thirty-four young adults participated in the study and were randomly divided into a training (TR; N=17; 27.45±3.41yrs; 1.74±0.08m; 69.35±10.8kg) and a control (CTRL; N=17; 28±4.37yrs; 1.73±0.07m; 68.3±10.79kg) group. TR and CTRL were assessed for postural balance at the beginning of the study (T0) and after one month (T1) consisting of: static balance (SB); dynamic balance on unstable boards of easy (DBE) and hard (DBH) level; balance under unexpected perturbation of the base of support (PER). For each condition, subjects performed five trials over a force plate (AMTI BP400600, US) to measure the CoP trajectory. During SB, the subjects quietly stood in an upright posture. During DBE and DBH, subjects stood on the unstable board, aiming to maintain it parallel to the ground. During PER, subjects received an unexpected perturbation of the base of support (direction: forward; displacement: 50mm; ramp rate: 200mm/s). During DBE and DBH, an inertial measurement unit recorded the angular displacement of the board to calculate three parameters of balance performance: full (FB), fine (FiB), and gross (GB) balance. During PER, the mean velocity, the first peak, and the maximal oscillations (□CoPMax) of the CoP trajectory were calculated in the 2.5s window after the perturbation. Moreover, the CoP trajectory was quantified in terms of regularity (Sample Entropy) in SB, UBE, and UBH conditions. The TR group underwent a month (T0-T1) of training (3 days/week) with increasing difficulty only using the easy-level unstable board.

RESULTS: Two-way ANOVA showed improvements in balance performance (T0 vs. T1) in the TR group for FB ($p<0.001$), FiB ($p<0.05$), and GB ($p<0.01$) both in DBE and DBH. Similarly, the PER task had significant increases (T0 vs. T1) in the first peak

(p<0.01) and□□CopMax (p<0.05). Sample Entropy parameters were significantly higher (p<0.001) after the training (T1) in DBE and DBH conditions.

CONCLUSION: The one-month training successfully improved dynamic balance performance. A transfer of the balance ability was observed towards a more difficult (i.e., easy to hard) and to an untrained (i.e., unexpected perturbation) balance task. The non-linear CoP measure showed a shift from voluntary to automatic postural control mechanisms also in the task where no training occurred.

IS-SH03 Unmasking Educator Struggles

PHYSICAL EDUCATION TEACHERS AS STREET-LEVEL BUREAUCRATS: A WAY OF UNDERSTANDING THE PROFESSION.

SEBELIUS, S.
MALMÖ UNIVERSITY

The physical education (PE) teacher profession is a profession with a long tradition, in Sweden it has existed since 1813. During large parts of the professions history in Sweden, it has struggled to increase its status, the subject and the profession have been marginalized compared to other school subjects and other teachers (Sebelius, forthcoming). Internationally, it is seen that the profession and the subject is marginalized. PE teachers are seen as less important than core subject teachers by colleagues and school management (Richards et at, 2018). In the last 15 years, research on learning and teaching in PE has been done in Scandinavia and Europe. However, this has primarily focused on students health. What has not been investigated to the same extent is the health and work situation of PE teachers. However, Swedish research (Sebelius, 2018) has shown that by understanding PE teachers as street-level bureaucrats (SLBs), a wider knowledge about their work situation can be created. The work of a SLB is characterized by the fact that they work with people (clients), have a great deal of discretion, have too few resources and work towards unclear goals. SLBs often experience states of stress stemming from having to navigate extensive workloads and conflicting demands from the policies they implement, their bosses, themselves, and their clients (Lipsky, 2010). The SLBs can deal with stress in different ways, for example by being more empathetic towards their clients and giving more of their personal time, which further increases their stress (Ropes & de Boer, 2022). Looking at the profession, there are certain risks associated with the stress of being a SLB. A Swedish study (Sebelius, forthcoming) shows that physical education teachers use different strategies to deal with the conditions that characterize their work as SLBs. They feel compelled to organize teaching which to some extent hinders their opportunity for both relevant subject teaching and competence development. This might be a problem both for the PE teachers working situation, but also for the development of the PE subject and the PE teaching profession, as well as for the status of the profession. Relevance Increased knowledge of the work situation of the PE teaching profession. Target audience PETE-researchers, PETE-teachers

NAVIGATING THE TRANSFORMATIVE LANDSCAPE OF PHYSICAL EDUCATION: INTEGRATING TECHNOLOGY WHILE PRESERVING PROFESSIONAL IDENTITY

CHOW, G.
THE EDUCATION UNIVERSITY OF HONG KONG

Physical Education (PE) is undergoing a transformative phase, driven by the outbreak of Coronavirus Disease 2019 and the subsequent need for virtual learning. Traditionally, PE has been conducted face-to-face and played a crucial role in childrens daily physical activity. However, the pandemic has necessitated disease prevention measures, including the suspension of in-person classes in Hong Kong. As a result, there is now a growing demand for virtual PE, leading to a shift from low-tech to high-tech integration in the learning environment. To meet the needs of 21st-century learners and integrate information technology (IT) and STEAM education, schools in Hong Kong have swiftly incorporated these elements into all subjects, including PE. The expectation is for PE to combine face-to-face teaching with technology, supplementing students learning through tools like self-administered fitness tests using motion tracking technology or wearable devices. The Education Bureau in Hong Kong actively collaborates with universities to equip PE teachers with the necessary technological and technological-pedagogical knowledge. While some progress has been made through professional development programs like the STEAM in PE initiative provided by the Education University of Hong Kong, there is still a need to ensure that all front-line practitioners have the required skills and knowledge. However, this shift towards technology integration in the PE curriculum may challenge a PE teachers sense of professional identity, as their training has traditionally emphasized subject- and pedagogical-related knowledge and skills. This can result in demotivation and a loss of autonomy in how they teach PE. Therefore, the objectives of this lecture are twofold: firstly, to explore the changes in the learning environment in the 21st century, encompassing worldwide health guidelines and emerging trends in technology education that PE teachers need to address; and secondly, to discuss whether PE teachers are capable of adapting to

these changes while maintaining their sense of autonomy, competence in teaching PE, and job satisfaction. By addressing these objectives, we aim to provide PE teachers with insights, strategies, and support in navigating the evolving landscape of PE education, ensuring they can effectively integrate technology while preserving their professional identity and job satisfaction.

DOES WORKING WITH CHILDREN AND ADOLESCENTS REALLY MAKE YOU HAPPY? – THE PHENOMENON OF PROFESSIONAL BURNOUT AMONG PHYSICAL EDUCATION TEACHERS

WILCZYNSKA, D.

UNIVERSITY OF PHYSICAL EDUCATION AND SPORT

Introduction: Research highlights that physical education teachers, as human service professionals, face a heightened susceptibility to occupational burnout. Delving into the burnout tendencies within this group is imperative for the holistic well-being of both educators and students. While these teachers play a pivotal role in instilling a healthy and active lifestyle among students, the inherent demands of their profession—juggling diverse classes, sustaining high energy levels, and navigating potential administrative pressures—can significantly contribute to burnout. Thus, this study intricately explores the impact of protective factors, such as personality traits and leisure-time activities, in alleviating the challenges of teacher burnout. Material and Methods: The group of participants consisted of 73 individuals. The age of the participants ranged from 18 to 63 years old. However, the study will continue as long as it is part of the developing project. The study employs a range of research methods, including the NEO-FFI Personality Inventory, the Maslach Burnout Inventory, and the Inventory of Physical Activity Objectives. Results: Initial findings indicate that personality traits such as neuroticism, extraversion, and conscientiousness were significantly correlated with professional burnout. It has also been observed that physical activity levels do not protect against burnout. Moreover, age and internship were not related to occupational burnout. Conclusions: Understanding the factors leading to burnout allows for targeted interventions and support systems to be implemented, ensuring that these educators can continue to inspire and guide students effectively. By addressing burnout in physical education teachers, we not only safeguard the mental and emotional health of the educators themselves but also enhance the quality of the educational experience for students, fostering a positive and sustainable learning environment. Relevance Increased knowledge of the work situation of the PE teaching profession. Target audience PETE-researchers, PETE-teachers

AEROBIC PRECONDITIONING DOES NOT FURTHER AUGMENT MUSCLE HYPERTROPHY DURING SUBSEQUENT RESISTANCE EXERCISE TRAINING IN HEALTHY OLDER ADULTS

BETZ, M., MONSEGUE, A.P., AUSSIEKER, T., HOUBEN, A.J.H.M., VERDIJK, L.B., VAN LOON, L.J.C., SNIJDERS, T.

MAASTRICHT UNIVERSITY

INTRODUCTION: Resistance exercise training is an effective treatment strategy to counteract the age-related loss of muscle mass and strength in older adults. However, there is a large inter-individual variation in muscle fiber hypertrophy following resistance exercise training in older adults. It has been hypothesized that an increase in muscle fiber capillarization and perfusion capacity are prerequisite to maximize muscle hypertrophy during resistance exercise training in older adults. We assessed whether 8 weeks of aerobic exercise preconditioning, to improve muscle fiber capillarization and perfusion capacity, augments the gains in muscle mass and strength during subsequent resistance exercise training in older adults.

METHODS: In a randomized parallel design, thirty-four healthy older adults (71±5 y) participated in 12 weeks of progressive resistance exercise training, preceded by either 8 weeks of aerobic preconditioning (AER) or no exercise control (CON). Muscle strength (1RM), aerobic capacity (VO2peak test), and muscle fiber characteristics (immunohistochemistry) were assessed at baseline, following 8 weeks of AER or CON, and after subsequent 12 weeks of resistance exercise training. Femoral artery blood flow and vastus lateralis muscle microvascular perfusion kinetics were assessed at baseline and following 8 weeks of AER or CON intervention. Thigh muscle volume (MRI-scan) was assessed before and after 12 weeks of resistance exercise training. Data were analyzed by two-way repeated-measures ANOVA. A statistical level of $P<0.05$ was accepted. All data are expressed as mean±SD.

RESULTS: Aerobic exercise preconditioning increased type I (C/Fi :+19±19%, $P<0.05$) and type II (C/Fi: +35±37%, $P<0.05$) muscle fiber capillarization, with no changes in the CON group (C/Fi Type I: +0±17% Type II: -3±26%). Whereas femoral artery blood flow remained unchanged, the vastus lateralis muscle microvascular perfusion capacity tended (interaction effect, $P=0.051$) to be lower during post-exercise recovery following aerobic exercise preconditioning, with no changes in the CON group. Subsequent resistance exercise training increased 1RM leg press (+16±10% vs +12±8%, respectively, $P<0.001$) and thigh muscle volume (+0.42±0.69 vs +0.31±0.62 L, respectively, $P<0.001$), with no differences between AER and CON group (interaction effects, $P>0.4$). No differences were observed in type I and type II muscle fiber hypertrophy in response to the entire intervention program between groups (interaction effect, $P>0.5$).

CONCLUSION: Aerobic exercise preconditioning increases in type I and type II muscle fiber capillarization in healthy older adults. Aerobic exercise preconditioning does not further increase muscle hypertrophy during subsequent resistance exercise training in healthy older adults. Both structural and functional microvascular characteristics do not seem to restrict the skeletal muscle adaptive response to resistance type exercise training in healthy older adults.

ECCENTRIC TRAINING INDUCES DIFFERENT MUSCLE MITOCHONDRIAL ADAPTATIONS IN OLD VERSUS YOUNG MEN

ANSALDO, M., SAZZI, C., BROCCA, L., PORCELLI, S., QUINLAN, J.I., PHLLIPS, B.E., SMITH, K., ATHERTON, P.J., NARICI, M., BOTTINELLI, R., PELLEGRINO, M.A., FRANCHI, M.V.

UNIVERSITY OF PAVIA

INTRODUCTION: Skeletal muscle aging is not only characterized by loss of muscle mass and power but also by mitochondrial impairments and reduced oxidative function (1). Resistance training (RT) is considered among the most effective strategies to counteract muscle atrophy and preserve muscle function (2). Moderate-intensity exercise based on eccentric (ECC) contractions has been proposed as an alternative to the classic conventional RT due to its potential efficacy in increasing muscle mass and function without requiring excessive effort for the elderly population (3,4). Notably, recent evidence showed significant improvement in mitochondrial function following chronic RT (5). However, the impact of eccentric-resistance training (ECC-RT) on mitochondrial adaptations is still not known. Thus, we investigated mitochondrial adaptations in response to 8 weeks of moderate ECC-RT in old (O) vs young (Y) individuals.

METHODS: Eight O (67±1.3 y.o.) and eight Y (25±6 y.o.) subjects underwent 8 weeks of moderate-load ECC-RT consisting of 4 sets of 15 repetitions performed at 60% of ECC 1RM, 3 times/week. Before the first (PRE) and after the last (POST) training session, knee-extensors maximal voluntary isometric contraction (MVIC) torque was assessed at 3 different joint angles 60°, 70°, 80° and maximum isometric torque value obtained over the three joint angles was chosen as MVIC peak value. Muscle volume (QV) was measured by MRI. Muscle biopsies were also collected from the Vastus Lateralis and markers of mitochondrial biogenesis, content, and dynamics were analyzed by western blot. Data were analyzed by two-way ANOVA.

RESULTS: After 8 weeks of eccentric resistance training, MVIC force increased in both O and Y (17 vs. 13%, respectively $p<0.05$ for both groups). QV increased in both O and Y (4% vs. 5%) ($p<0.001$) ($p<0.01$). After training, PGC-1α decreased in O (-44%, $p<0.05$) while no changes were observed in Y ($p>0.05$). TOM20 and CS decreased in O (-29% and -31% respectively, $p<0.01$) but they remained unaffected in Y ($p>0.05$). MNF1 increased in Y (+65%, $p<0.05$), while did not change in O ($p>0.05$). Regarding mitochondrial fission, levels p637DRP1 decreased in O (-41%, $p<0.05$) and not in Y ($P>0.05$); p616DRP1 increased in Y (+300%, $p<0.05$) and not in O ($P>0.05$).

CONCLUSION: Despite the positive effect on muscle mass and strength in both O and Y, ECC-RT dampened mitochondrial biogenesis, reduced mitochondrial content, and promoted fission in O while both fission and fusion increased in Y. We can hypothesize an age-dependent response to moderate ECC-RT, with a negative effect on mitochondrial adaptations in O compared to Y. This is of particular interest, as such exercise modality, which could be tailored for elderly populations for its positive neuromuscular adaptations could not be entirely suitable for counteracting reductions in oxidative function.

EFFECT OF PULMONARY MECHANORECEPTORS ON SYMPATHETIC OUTFLOW DURING MILD INTENSITY EXERCISE IN HEALTHY HUMANS

EWALTS, M., GRIFFITHS, T.D., DOUGLAS, A., JENKINS, E., OLIVER, S., STEMBRIDGE, M., MOORE, J.

BANGOR UNIVERSITY, UK

INTRODUCTION: During exercise, increased sympathetic vasomotor outflow optimizes blood flow to exercising muscles and maintains blood pressure. Several mechanisms activate vasomotor outflow during exercise, including central command, muscle afferent feedback, and the arterial baroreceptor reflex. We have shown that a sustained increase in pulmonary arterial pressure, like that displayed during exercise, elicits sympathetic activation in experimental animals and humans exposed to high altitude hypoxia. The aim of this study was to investigate an additional mechanism of exercise induced sympathetic activation, which potentially arises from mechanoreceptors located in the pulmonary arterial system.

METHODS: To address our aim, 12 healthy individuals (F=2; 28±7 years old) were studied under hypoxic conditions, a setting designed to elevate pulmonary arterial systolic pressure (PASP) above normal. The experiment comprised of three conditions: i) rest in acute hypoxia (FiO_2=12.5%; baseline); ii) mild intensity exercise (RPE 11-12) in acute hypoxia (EX) and iii) mild intensity exercise in acute hypoxia combined with inhalation of vasodilator nitric oxide (iNO, 40 ppm) to selectively reduce PASP (EX reduced PASP). Muscle sympathetic nerve activity (MSNA; microneurography), ventilation (VE; breath-by-breath online gas collection system), blood pressure (BP; photoplethysmography) and heart rate (HR) were measured continuously, and ratings of perceived exertion was assessed in the final minute of exercise. PASP was measured using Doppler echocardiography. Vascular-sympathetic baroreflex gain was determined using spontaneous baroreflex sensi-

tivity. To detect differences between conditions, a one-way repeated measures ANOVA was performed, followed by Bonferroni corrected T-tests. A statistical level of p<0.05 was accepted. All data are expressed as mean±SD.

RESULTS: PASP increased during exercise (baseline 28±7 vs. EX 42±9 mmHg; P<0.001) and was lower in EX reduced PASP vs EX (42±9 vs. 36±8 mmHg; P=0.018). MSNA burst frequency increased by 61% during exercise (baseline 21±7 vs. EX 34±9 burst/min; P=0.001), which was partially reversed (12%) by reducing PASP with iNO during exercise (EX 34±9 vs. EX reduced PASP 30±9 burst/min; P=0.027). Reducing PASP during exercise also reduced MSNA operating point (burst incidence; 28±9 vs. 25±8 bursts/100Hb; P=0.030), without changing diastolic operating pressure (79±16 vs. 78±12 mmHg; P=0.307), or spontaneous vascular-sympathetic baroreflex gain (P=0.726). Reducing PASP during exercise had no effect on HR (P=0.999), VE (p=0.159), workload (P=0.701) or RPE (P=0.667).

CONCLUSION: Lowering PASP reduced sympathetic outflow and reset vascular sympathetic baroreflex control of MSNA downward during hypoxic exercise. Our findings indicate that, in addition to established neural mechanisms, an input from pulmonary arterial mechanoreceptors contributes to sympathetic activation and arterial baroreceptor reflex resetting during exercise.

SEX DIFFERENCES IN CARDIAC AND RESPIRATORY RESPONSES DURING EXERCISE AT SEA LEVEL AND HIGH ALTITUDE.

CALLOVINI, A., FORNASIERO, A., SAVOLDELLI, A., BORTOLAN, L., PELLEGRINI, B., CAPELLI, C., SCHENA, F.

CERISM - UNIVERSITY OF VERONA

INTRODUCTION: Sex differences in exercise physiology are underrepresented in the literature, particularly in specific contexts such as High Altitude (HA)1. The aim of this study was to investigate the influence of sex on the cardiac and respiratory responses to exercise at sea level (SL) and HA.

METHODS: Eight women (F; VO2max:49±3 mL/kg/min) and eight height-matched men (M; VO2max:59±5 mL/kg/min) underwent a VO2max test, at SL (20.9 FiO2) and at a simulated altitude of 4500m (11.8 FiO2). These were followed by two pulmonary function (PF) evaluation sessions, one at SL and one at HA, where cardio-respiratory responses, Inspiratory Capacity (IC), and Diffusion Capacity (DLCO) were assessed during moderate (mod), heavy (heav) and severe (sev) exercise.

RESULTS: VO2max (F:-32%, M:-31%), VEmax (F:-8%, M:-7%) and HRmax (F:-6%, M:-6%) were significantly reduced at HA (all p<0.001). During PF, submaximal VO2 was lower at HA (p<0.001) in both sexes, with a sex*intensity interaction effect (p<0.001) indicating progressively higher sex differences with increasing exercise intensity regardless of condition. SpO2 was significantly reduced at HA (≈ -29%), with no general effect of 'sex' or 'intensity'. Submaximal ventilation (VE) was similar between sexes at SL, whereas it was significantly lower during heav and sev at HA in women if compared to men (condition*intensity*sex interaction, p=0.021). Cardiac responses (i.e., Q, SV, and HR) showed a 'FiO2*intensity' interaction (p=0.028, 0.004, and 0.001, respectively), displaying a trend toward a decrease at HA as exercise intensity increased (Q: ≈+6, -6, -10%; SV: ≈+4, -5, -6%; HR:≈+2, -0.4, -4% for mod, heav and sev, respectively). No sex differences were detected in these variables. Breathing responses derived from IC were reduced in females, with no additional effect of HA. DLCO values, even when corrected for Alveolar volume (Va), were lower in females at both SL and HA (p=0.023) for all the intensity domains. Finally, a reduction in DLCO (mod:-11 and -1%; heav:-12 and -6%; sev:-7 and -12% for M and F, respectively) and DLCO/Q ratio (mod:-16 and -8%; heav: -8 and -3 %, sev: -4 and -3% for M and F, respectively) was noted in both sexes at HA (p<0.001).

CONCLUSION: Similar maximal and submaximal oxygen consumption differences between F and M have been found at SL and HA. SpO2 was reduced by hypoxia, but similar between sexes in the two conditions. Cardiac responses (e.g, HR, SV and CO) were unaffected by sex at both maximal and submaximal levels, while respiratory responses (IC and DLCO outcomes) have been confirmed to be impaired in women2, with no additional effect of HA on the sex gap already present at SL in these variables. VE differences between sexes found at HA but not SL underline the central role of ventilatory responses in determining sex differences to exercise at HA.

OP-BM03 Biomechanics II

LOWER-LIMB FORCE-PRODUCTION CAPACITIES IN ALPINE SKIING DISCIPLINES: CRITICAL FORCE MATTERS?

CHOLLET, M., HINTZY, F., BOWEN, M., MOREL, B., SAMOZINO, P.

UNIVERSITÉ SAVOIE MONT BLANC

INTRODUCTION: In competition, there are four main alpine skiing events: slalom (SL), giant slalom (GS), super giant slalom (SG), and downhill (DH). Each event differs in race duration, turn number, turn radii and speed reached (1). Therefore, the average turn-by-turn forces and impulses the skier applies vary across events (2). The off-snow lower-limb isometric force has been previously shown to be related to skiing event-specific performance (3). Nevertheless, despite evidence demonstrating the appearance of fatigue after repeated turns (4), this study only focused on free-fatigue maximal force capaci-

ties without considering strength endurance capacities The latter can be characterized by the critical force, i.e. the maximal force which can be sustained without inducing acute fatigability. Therefore, the present study aimed to test the relationship between skiing event-specific performance and maximal isometric force, rate of force development and critical force.

METHODS: Nineteen skiers (27 to 100 FIS points) participated in this study. Maximal isometric force (Fmax), maximal rate of force development (RFDmax), and critical force (CF) were assessed using an isometric leg press ergometer within the same session. CF was determined using a Ramp Above Critical Level Endurance Test (5). Briefly, this test consisted of repeated submaximal isometric 2s contractions spaced by 2s of rest during a 300s-decreasing ramp test from 80% to 0% of Fmax. Every 28s, maximal isometric force was assessed. Based on the model of Bowen et al. (6), CF was computed as the targeted force at the instant when the maximal isometric force stopped to decrease and started to recover. Performance indexes in each skiing event (SL, GS, SG, and DH) were defined as the FIS points for the 2022/2023 season. Multiple linear regressions were used to understand whether interindividual variability in each physical capacity (Fmax, RFDmax, and CF) explains variability in event-specific performance.

RESULTS: SL performance was only and positively associated with RFDmax (model R2 = 0.41, p = 0.004). GS performance was only and positively associated with CF (model R2 = 0.36, p = 0.008). SG performance was only and positively associated with CF (model R2 = 0.37, p = 0.008). DH performance was positively associated with CF and Fmax (model R2 = 0.89, p < 0.001).

CONCLUSION: This study demonstrates specific associations between skiing performance and off-snow physical capacities. Performance is mainly explained by RFDmax in SL, CF in GS, CF in SG and both CF, and Fmax in DH. Physical capacities explained a higher part of skiing performance in DH compared to the other events. These results evidence the importance of strength endurance capacities in skiing performance and can help trainers and skiers in event-specific physical preparation.

EFFECT OF VELOCITY ON CRITICAL TORQUE, CRITICAL POWER AND WORK ABOVE CRITICAL INTENSITY: EXPERIMENTAL EVIDENCE IN PEDALING

BOWEN, M., SAMOZINO, P., MOREL, B.
SAVOIE MONT BLANC UNIVERSITY

INTRODUCTION: The Critical Power is the severe intensity domain boundary above which fatigue develops drastically and non-steady-state physiological responses occur (1). However, a given power can be developed using different combinations of torque and velocity. During maximal effort, velocity is known to influence the maximal torque or power, which is well described by linear force-velocity or polynomial power-velocity relationships. Although a vast literature has studied critical power, relatively few studies have focused on the effect of the velocity condition. In addition, only 2 velocity conditions were usually tested given the physical hardship and/or time-consuming aspects of assessing critical power using time to exhaustion or 3-min all-out methods (2). Thanks to the development of a new method for assessing critical power during a single 5-min submaximal exercise: the Ramp Above Critical Level Endurance Test (RACLET) (3), the study's aim was to test the effect of the velocity condition on critical power (Pc) and torque (Tc) over a large spectrum in pedaling.

METHODS: Based on Bowen model (4), which establishes the proportionality between work accumulation above the critical intensity (Wac) and fatigability during exercise in the severe domain, RACLET was used to determine Tc and Pc under different velocity conditions. Briefly, this test consisted of a 5-min isokinetic pedaling decreasing power ramp, where maximal power was assessed every 30 s from a 6-pedal-strokes sprints. The ramp is designed such that the target power starts above and decreases below Pc without leading to exhaustion. Thus, Pc was determined to be the power target when the maximal capacities stopped decreasing and began to recover. Twenty participants realized five RACLET under different pedaling rate conditions: from 40 to 120, every 20 RPM. From each RACLET, the model was fitted to the maximum power data to obtain the initial power (Pi) & Pc parameters for each cadence. The cadence effect on Tc, Pc, and Wac was modeled and tested using ANOV

RESULTS: The model's goodness of fit on the RACLET experimental data (changes in the maximal power over time) was excellent (mean adjusted R^2=0.89, RMSE=5%Pi). Tc decreased significantly with the increase in cadence (p<0.001; from 37.3±4.5 to 18.0±4.2 %Ti for 40 to 120 rpm). Furthermore, the Tc as a function of velocity was well described by curved function (median R^2 = 0.92). The optimal velocity that allows to maximize the Pc was 67.2 ± 19.3 RPM

CONCLUSION: The results show that it is possible to determine the individual model parameters Tc & Pc, at several velocities using a newly validated submaximal not-to-exhaustion test (RACLET). This allowed us to demonstrate that the critical power was affected by the velocity conditions. The maximum critical power was produced under individual optimum cadence conditions. The velocity condition is crucial when considering and testing the critical power.

AN INNOVATIVE METHOD FOR ASSESSING ISOMETRIC CRITICAL FORCE WITHOUT EXHAUSTION IN CLINICAL CONTEXT: THE RAMP ABOVE CRITICAL LEVEL ENDURANCE TEST.

DI DOMENICO, H., BLERVAQUE, L., BOWEN, M., PERNOT, J., SAMOZINO, P., MOREL, B.
SAVOIE MONT-BLANC UNIVERSITY

INTRODUCTION: Critical power is an important fatigue threshold in exercise physiology, separating moderate to severe intensity domains. When muscle effort is performed above the critical force (Fc), acute muscle fatigue drastically occurs. This critical threshold has great potential application in optimizing athletic training programs and performance as well as improving the life quality for chronic disease (e.g. chronic obstructive pulmonary disease (COPD)) patients (1). Historically, Fc has been provided by the asymptotic force-time relationship, obtained during multiple time-to-exhaustion or all-out test. The difficulty of these tests prevents them from being used routinely in clinical context. Based on Bowen et al. (2) model, we proposed an innovative non-exhaustive test to determine the Fc: the Ramp Above Critical Level Endurance Test (RACLET). The aims of this study were to i) test the validity of the RACLET and ii) its feasibility with COPD patients.

METHODS: Sixteen healthy participants and ten COPD patients completed a RACLET on an isometric knee extension ergometer. The test consists in a 5-min decreasing ramp, from severe to moderate intensity domains, composed of intermittent contraction (3s on, 2s off) and brief maximal voluntary contraction (MVC) every 30s. RACLET started at 60% of the initial maximal force (Fi) and gradually decreased to reach 0 N after 5 min. Visual feedback enabled the participant to follow the target force. Healthy participants also performed, on a separated day, a 5-min all-out isometric test. Forces reached during all-out or MVCs performed during RACLET were modelled using derived equations based on: $Fmax(t) = -(1/Tau)*int(F(t)-Fc)dt+Fi$, where F is the target force and Tau is a time constant (2). The validity of the RACLET was assessed by examining the correlation and the root-mean-square error (RMSE) compared to the gold standard method being the 5-min all-out.

RESULTS: The model's goodness of the fit on RACLET and all-out test experimental data was excellent (median $r2 = 0.96$ and 0.97, respectively). Fi, Fc and Tau obtained from RACLET (656 ± 152 N, 283 ± 80 N and 64 ± 33 s, respectively) and from all-out test were highly correlated ($r2 = 0.94$, 0.92, 0.83, respectively, all $p<0.001$, RMSE = 6.4, 5.9, 20.8%). All COPD patients were able to complete the RACLET, the goodness of fit being excellent (median $r2 = 0.95$). The Fc expressed relatively to initial capacity was significantly lower than healthy participants (33 ± 11 vs 41 ± 7 %Fi respectively, $p<0.05$).

CONCLUSION: Compared to the gold standard all-out method, the RACLET is valid to assess Fc in isometric knee extension. This innovative test does not lead to exhaustion. Thus, it has demonstrated to be feasible to determine Fc in COPD patients (stage 1 to 3). The RACLET could thus be a useful tool for determining a muscle intensity threshold (i.e. Fc) to tailor intervention or evaluate the effect of patient rehabilitation.

EXPLORING ANTICIPATION EFFECTS ON KINEMATIC PATTERNS DURING THE INITIAL CONTACT PHASE OF CHANGE OF DIRECTION MOVEMENTS

KUEHNE, M., SANIN, C., MOHR, M.
UNIVERSITY OF INNSBRUCK

INTRODUCTION: In evasion sports, ruptures of the Anterior Cruciate Ligament (ACL) frequently occur with minimal opponent contact within the first 50 ms after the initial contact (IC) of change of direction (COD) movements [1]. One influencing factor for the observed movement pattern is whether or not the athlete was planning the sidestep in advance. Although previous research has suggested more injury-prone movements in unplanned CODs, conflicting results and interpretations exist, e.g. regarding knee flexion [2]. The disagreement may stem from little information available in the COD kinematics of a single point in time (such as IC). We aimed to provide further insight into the anticipation effect on CODs regarding ACL injury risk by investigating the joint angle progression after IC during multiple CODs in an on-field setting mimicking real game scenarios.

METHODS: Twenty male soccer players performed 12 maximum-speed COD sequences in a setup of 6 COD options (45°, 90°, 135°; L, R) on artificial turf. For half of the trials, participants knew the running direction in advance (planned). The other half were unplanned trials, in which participants received their direction cue during the run-up. IMU sensors (Noraxon Ultium Motion) were placed on 8 body parts and joint angles were estimated by the corresponding software (Noraxon myoMotion). Using linear mixed effect models (factors anticipation and COD angle), the change in angle from IC to IC+50 ms was examined for knee flexion and abduction, ankle flexion, hip abduction and flexion, trunk flexion, lateral lean and rotation and as pelvis orientation ($alpha = 0.05$).

RESULTS: A significant main effect of anticipation was found for knee flexion, revealing a larger flexion movement in the planned ($M = 13.3$) compared to the unplanned condition ($M = 10.7$, $p = 0.002$). Significant interaction effects (COD angle x anticipation) highlighted angle-dependent differences of planned vs. unplanned CODs for trunk rotation ($p = 0.004$) and hip flexion ($p = 0.001$). Main effects of COD angle were found for all joint angles except knee abduction.

CONCLUSION: In planned CODs, a larger knee flexion movement in the initial contact phase may enable a safer absorption of initial momentum compared to unplanned CODs, possibly reducing ACL injury risk [1]. Sagittal plane ankle and hip movements were comparatively small for both conditions, especially at sharper COD angles. This suggests a low contribution of hip and ankle and a high contribution of the knee to energy absorption during CODs. While for some variables

the observation of a single posture (e.g. at IC) might be sufficient for risk assessment, analyzing the change in joint angles in the critical first 50 ms of contact can help to gain more insight into the movement strategies that may prevent or provoke ACL injuries.

ACUTE EFFECTS OF UNPLANNED AND PLANNED HOP-LANDING TRAINING ON DECISION-MAKING AND SIDE-STEP CUTTING KNEE BIOMECHANICS

KONISHI, M., NICHOLAS, C.C.2, TAKEMURA, M.1, CORTES, N.2,3

1 UNIVERSITY OF TSUKUBA, TSUKUBA, JAPAN; 2 UNIVERSITY OF ESSEX, COLCHESTER, UNITED KINGDOM; 3 GEORGE MASON UNIVERSITY, FAIRFAX VA, USA

INTRODUCTION: Anterior cruciate ligament (ACL) injuries occur frequently in open-skill (unanticipated/unplanned) sports, and poor decision-making may be a risk for noncontact ACL injury (1). While athletes experience high-level neurocognitive demands within unanticipated athletic situations, contemporary ACL injury prevention programs (IPPs) focus typically on improving closed-skill (anticipated/planned) tasks/exercises alone (e.g., planned jump landing (2)). Contrastingly, ACL IPPs that contain more unplanned tasks/exercises more characteristic of open-skill athletic situations are uncommon. Therefore, this study aimed to investigate the acute effect of unplanned versus planned hop-landing training on decision-making and knee biomechanics during unanticipated side-step cutting motions.

METHODS: Thirty-two recreational athletes (16 female, 16 male) were assigned randomly to the unplanned training group (UT-G) or the control group (CON-G). Both groups completed dominant-leg training involving three multi-stage athletic tasks: hop-landing from a 30cm high box (HL30) + 45° side-step cutting; HL30 + sticking the landing; HL30 + forward linear running. For each task, 2 blocks × 10 trials were completed (total = 60 trials). The UT-G performed unplanned training using three randomly ordered light stimuli triggered by a wireless sensor (Swift Neo, Swift Performance, Australia): each stimulus cued specifically one of the three athletic tasks during the HL30. The CON-G performed planned training: each stimulus was presented before the HL30. During training, errors were counted for each task and designated as deviations from instructions that defined a successful trial. Error rate was calculated: number of error trials ÷ 60 total trials. Three-dimensional biomechanical data were collected from the dominant limb for all athletic tasks before and after training. Knee peak kinematic/kinetic values within 0-50% of stance phase during the unanticipated 45° side-step cutting tasks were extracted from the data. Task error rate and knee biomechanical values were analysed using a two-way repeated-measures ANOVA to determine the effects of group, training, and any interactions.

RESULTS: There were significant interactions for group and training for task error rate ($F(1.32) = 8.55$, $P = 0.01$) and peak knee abduction angle during unanticipated side-step cutting ($F(1.32) = 6.56$, $P = 0.02$). Specifically, for the UT-G only, these variables changed beneficially after training.

CONCLUSION: Only the UT-G improved the task error rate and knee biomechanics linked to noncontact ACL injury during unanticipated side-step cutting. Incorporating athletic tasks under neurocognitive demands into ACL IPPs may contribute to more optimal preparations for open-skill sporting environments. Future research should explore the mechanisms underlying the observed biomechanical improvements.

OP-PN20 Energy Metabolism

ANAEROBIC SPEED RESERVE OF ELITE 400-M SPRINTERS

RIESTENPATT, S., RAPPELT, L., DONATH, L.

GERMAN SPORTS UNIVERSITY COLOGNE

INTRODUCTION: 400-m sprinting relies on predominantly anaerobic metabolism. The aerobic contribution is estimated to 40% of the total energy contribution [1]. The concept of the anaerobic speed reserve (ASR) integratively considers aerobic and anaerobic properties, defined as the velocity difference between maximal sprinting speed (MSS) and maximal aerobic speed (MAS). The corresponding Speed Reserve Ratio (SRR) was initially introduced to determine 800-m elite athletes' performance profiles and types [2]. In this regard, profiling of 400-m athletes considering their relationship to personal best (PB) are missing. We aimed at investigating the contribution of endurance and speed capabilities of 400-m elite sprinters to their PB in order to improve sprint diagnostics and training programming.

METHODS: The ASR of 18 sprinters (elite female, n=7, 23±2 years, 400-m-PB: 53.0±1.3s; elite male, n=5, 23±3 years, 400-m PB: 46.7±1.0s; highly-trained female, n=6, 20±3 years, 400-m-PB: 57.6±2.5s) was assessed. Using a laser velocity guard (LAVEG), MSS was determined as instantaneous velocity during a 60-m all-out sprint. Maximal oxygen uptake

(VO2max) and velocity at VO2max (MAS) was determined through ramp test on a treadmill. Additionally, fixed lactate threshold at 4-mmol/L blood lactate (vL4) was determined in the laboratory using an incremental step test. Profiles of three athlete subgroups were created. The SRR (MSS/MAS) was calculated according to Sandford and colleagues [1].

RESULTS: Strong statistically significant negative correlations with PB were found for maximal sprinting speed ($r = -0.96$, $p < 0.001$) and maximal aerobic speed ($r = -0.74$, $p < 0.001$). Moderate statistically significant negative correlation with PB was found for vL4 ($r = -0.60$, $p = 0.008$) but not for VO2max ($r = -0.46$, $p = 0.053$). Using a multiple linear regression, a model was created to generate the following prediction ($R2 = 0.96$, Residual standard error = 0.97):

PB [s] = 113.6815 -5.1122MSS [m/s] - 2.6023MAS [m/s] + ε

A very low variance inflation factor of 1.61 indicates a low risk of multicollinearity. The standardized beta weights for MSS and MAS are -0.80 and -0.27, respectively. Adding vL4 and/or VO2max to this initial model did not increase model fit (Likelikood ratio test: $p \geq 0.412$). Subgroups of 400-m sprinter types were defined by SRR: 200-400 m ≥ 1.75, 400 m ≤ 1.74 to ≥ 1.66, 400-800 m ≤ 1.65.

CONCLUSION: Sprinting Speed is the best predictor of 400-m performance. MAS should be used rather than VO2max alone as MAS has a better negative relationship to 400-m PBs. Calculating SRR can be useful for identifying an athlete's 400-m profile, potentially facilitating individualized training prescriptions. Future research is needed to test individualized training prescriptions based on ASR diagnostics. Training programs for aerobic speed improvements that do not impair sprinting speed are crucial.

MANIPULATION OF RESTING LACTATE LEVELS AND NUTRITIONAL STATUS UNDERESTIMATES VLA.MAX BY REDUCING NET LACTATE ACCUMULATION

SCHÜNEMANN, F., POHL, A., GEHLERT, S.

UNIVERSITY OF HILDESHEIM

INTRODUCTION: In elite sports, the determination of anaerobic glycolytic performance (vLa.max) is becoming increasingly popular. vLa.max is determined e.g. in sprint tests, where firstly glycolysis is maximally activated, followed by the calculation of the quotient between the difference of peak blood lactate (Lapeak) and resting lactate (Larest), and the difference between exercise time and alactic time is calculated. Unintentional variations in lactate levels, such as elevated Larest levels, may affect vLa.max results because of their high impact on the numerator in this calculation.

Aim: To evaluate the effects of variations in carbohydrate availability and Larest on VLamax.

METHODS: Twenty-one subjects (13 male, 8 female; age: 23.1 ± 2.0 years, height: 177.1 ± 8.4 cm, weight: 74.2 ± 11.9 kg) completed five 15-second running sprint tests on five separate testing days under five different conditions: baseline: Larest ≤1.5 mmol·L-1; lactate+: Larest ≥2.5 mmol·L-1; CHO-: carbohydrate intake: ≤1g·kg-1 BW · d-1 for three days; CHO+: carbohydrate intake: ≥9g·kg-1 BW · d-1 for one day; and acuteCHO: 500ml juice sparkling water beverage.

Specifically, after a 10-min warm-up, subjects rested until reaching specified Larest. Subjects then carried out a 15s maximal sprint on a running track. Blood lactate was determined every minute until minute 10' after the sprint.

A Friedman ANOVA with Dunn's post hoc test was used to assess differences between conditions and time points. Statistical significance was accepted at $p<0.05$. Data are presented as mean ± standard deviation.

RESULTS: vLa.max (mmol · L-1 · s-1) was 0.59 ± 0.09 in baseline, 0.51 ± 0.01 in lactate+, 0.53 ± 0.1 in CHO-, 0.54 ± 0.1 in CHO+ and 0.57 ± 0.1 in acuteCHO. Significant differences were observed between vLa.max values from baseline and lactate+ ($p<0.001$) and baseline and CHO- ($p<0.05$). The mean delta (Δ) value, consisting of the difference between Larest and Lapeak (mmol · L-1), was 6.91 ± 1.0 in baseline, 5.99 ± 1.26 in lactate+, 6.15 ± 1.19 in CHO-, 6.32 ± 1.23 in CHO+ and 6.67 ± 1.25 in acuteCHO. Significant differences were identified between Δbaseline and Δlactate+ ($p<0.01$), Δbaseline and ΔCHO- ($p<0.05$), as well as Δbaseline and ΔCHO+ ($p<0.05$).

CONCLUSION: Variations in carbohydrate intake and Larest levels may lead to a reduction in net accumulated lactate levels in a vLa.max test. Therefore, careful consideration and adjustment of test methodology are necessary to avoid underestimating vLa.max in athletes.

EFFECT OF HYPOXIA ON MAXIMAL FAT OXIDATION RATE DURING INCREMENTAL CYCLING

HASSANEIN, Y., IBRAHIM, D., MURIAS, J., TOWNSEND, N.

HAMAD BIN KHALIFA UNIVERSITY

INTRODUCTION: The maximum fat oxidation rate (MFO) has been suggested to provide useful information regarding endurance training status in athletes, but also as an index of metabolic health in untrained populations. Training in hypoxia is a popular method used by athletes for the purpose of performance enhancement and is emerging as a therapeutic intervention to improve cardiometabolic health. It is known that the addition of hypoxia induces a shift towards carbohydrate utilization, however the few studies that examined fat oxidation in hypoxia reported equivocal results. This may be due to differences in the methods used to normalize relative intensity. The aim of this study was to evaluate MFO matched intensity relative to the respiratory compensation point (RCP) in both normoxia (NORM) and hypoxia (HYPO).

METHODS: Seventeen recreationally active adults (5F/12M; age: 36.2±7.4 yr; weight: 76.6±13.1 kg) performed a ramp and a step test, in NORM (FiO2≈21%) and HYPO (FiO2≈13.5%), on separate days. The gas exchange threshold (GET), RCP and VO2peak were determined from the ramp tests. The step test involved 6 constant load stages (4-8 min) matched for intensity relative to the RCP in each condition. Indirect calorimetry was used to estimate MFO rate during the step test. Each participant's diet, fasting hours, and testing time were consistent between conditions. Paired t-tests and a 2-way ANOVA were used to examine differences between NORM and HYPO. Pearson correlation was used to assess the relationship between MFO and GET.

RESULTS: Fat oxidation rate was decreased in HYPO across all stages (main effect of condition: P<0.001; η_p^2=0.64). Subsequently a 25% decrease in MFO in HYPO (0.26 ±0.08g.min-1) compared to NORM (0.35±0.08g.min-1; P<0.001; d=1.24) was observed. %VO2peak where MFO occurred was similar in HYPO (39±21%) and NORM (39±21%; p=0.97), however the correlation between MFO and GET (as %VO2peak) was not significant in either NORM (r = 0.3; P>0.05) or HYPO (r = 0.07; P>0.05).

CONCLUSION: MFO was markedly decreased in hypoxia during step incremental cycling where each workload was normalized to RCP. Furthermore, the decrease in fat oxidation was apparent at all workloads and was greater than expected from the lower absolute exercise intensity. This suggests the reduced fat oxidation was not fully accounted for by a decrease in absolute workrate alone, but there was an independent effect of reduced oxygen availability. Hypoxia did not alter the relative intensity, as a percentage of VO2peak where the MFO occurred.

IL-15 IS ASSOCIATED WITH FAT OXIDATION DURING CARDIOPULMONARY EXERCISE TEST IN ENDURANCE ATHLETES

ALVES DE FONTES-JÚNIOR, A., SIERRA, A.1, DE OLIVEIRA, L.1, DE SOUSA, C.1, CURY-BOAVENTURA, M.

1 UNIVERSIDADE CRUZEIRO DO SUL, 2 UNIVERSIDADE DE SÃO PAULO

INTRODUCTION: The magnitude of physical exertion possibly represents a significant regulator of the secretion of several myokines. It has been reported that acute exercise increases the activity of PPARδ and PGC-1α through the release of myokines, as IL-15, stimulating mitochondrial biogenesis, lipid oxidation and browning of white adipose tissue (WAT) and benefiting the cardiometabolic system. However, few studies have evaluated the role of IL-15 in cardiometabolic function in different exercise loads. The present study investigated the correlation between IL-15 plasma concentration and cardiometabolic parameters at the three thresholds of a cardiopulmonary exercise test (CPET) in endurance runners.

METHODS: Seventy-two endurance athletes, between 30 and 55 years old (mean ± 41.4), healthy and with no history of cardiovascular diseases, participated in this study. Blood samples were collected at rest to determine the plasma levels of interleukin (IL)-15 by enzyme immunosorbent assay. The CPET test was performed using a treadmill protocol (TEB Apex 200, TEB, São Paulo, Brazil), with a fixed inclination of 1% and the speed starting at 8km/h increasing 1km/h per minute until the runners maximum exhaustion. The analysis of expired gases was performed in a breath-by-breath system (CPET Quark, Cosmed, Rome, Italy) at the first, second and third thresholds (anaerobic threshold, AT, respiratory compensation, RC, and Peak, respectively). Correlations between the parameters IL-15 and CPET were performed using Spearmans test. Statistical significance was accepted at $p < 0.05$ in all analyses.

RESULTS: The data showed that IL-15 levels were positively correlated with speed (km/h) in AT, RC and Peak (r= 0.3595, p= 0.0019, r= 0.2814, p= 0.0166, r= 0.2749, p= 0.0194, respectively) and with fat oxidation (%) in AT and RC (r= 0.4618 p= <0.0001, r= 0.3007 p=0.0103,respectively). Moreover, IL-15 levels also had inverse correlation with relative quotient (RQ) in AT, RC and Peak (r= -0, 469 p= <0.0001, r= -0.4129 p= 0.0003, r= -0.2587 p= 0.0282, respectively), with VE/VO2 in AT, CR and Peak (r= -0.3993 p= 0.0005; r= -0.3661 p= 0.0016; r= -0.3669 p= 0.0015, respectively) and with CHO (%) in AT and RC (r= -0.4879 p= <0.0001; r=-0.3007 p= 0.0103).

CONCLUSION: IL-15 is associated with greater lipid oxidation in all thresholds of a cardiopulmonary exercise test demonstrated by higher % of fat oxidation and RQ which may can sustain the exercise longer in each threshold. Our findings suggest that IL-15 is crucial to improve lipid metabolism and promote resistance in endurance runners.

ACUTE EFFECTS OF PHOSPHODIESTERASE-5 INHIBITION ON EXERCISE TOLERANCE AND THE PHYSIOLOGICAL RESPONSES TO MODERATE- AND SEVERE-INTENSITY EXERCISE IN HUMANS

GOMES BERNARDES, A., GABARDO, J.M.2, OLIVEIRA, L.S.3, MITAMURA, F.M.3, AGUIAR, A.F.3, ALTIMARI, L.R.2, DELL'ANNA, S.1, DE GIORGIO, A.1, BALDARI, C.1, BUZZACHERA, C.F.4

1 ECAMPUS UNIVERSITY, ITALY; 2 STATE UNIVERSITY OF LONDRINA, BRAZIL, 3NORTH UNIVERSITY OF PARANÁ, BRAZIL, 4UNIVERSITY OF PAVIA, ITALY.

INTRODUCTION: The nitric oxide (NO)-3'5'cyclic guanosine monophosphate (cGMP) signaling pathway plays a plethora of important roles in the human body. Recent studies suggest that increased NO production can enhance skeletal muscle function and improve exercise performance in some circumstances. The effects of elevated cGMP production on exercise performance, however, are less clear. While some authors have demonstrated improvements, others have shown no effect on exercise tolerance following the inhibition of phosphodiesterase-5, a member of a larger group of phosphodiesterase enzymes that deactivate cGMP. The inconsistencies found in previous studies are not well understood and warrant further research. We, therefore, investigated the effects of phosphodiesterase-5 on exercise tolerance and the physiological responses to moderate- and severe-intensity exercise.

METHODS: Twelve recreationally active men (mean age 23 ± 4 years) volunteered for this study. Each participant visited the laboratory on five separate occasions. On Day 1, they underwent a ramp incremental exercise test on an electronically

braked cycle ergometer to establish gas exchange threshold (GET) and peak oxygen uptake (VO2peak). Subsequently, on Days 2-5, participants were administered, in a randomized, double-blind, crossover manner, a single tablet containing either placebo or tadalafil citrate (20 mg) 80 minutes prior to completing three "step" exercise bouts: two at moderate intensity followed by one at severe intensity. Following a 7-d washout period, participants repeated the tests to complete a total of four moderate-intensity exercise bouts and two severe-intensity exercise bouts for each experimental condition. Pulmonary gas exchange and ventilation and NIRS-derived muscle oxygenation were continuously monitored throughout the tests. Blood samples were collected to determine blood lactate concentration 20 seconds before the onset of the first step exercise bout and 20 seconds following exhaustion during the severe-intensity exercise bout.

RESULTS: Pulmonary gas exchange and ventilation and NIRS-derived muscle oxygenation responses to either moderate- or severe-intensity exercise did not show significant differences between the two experimental conditions. However, the phosphodiesterase-5 inhibition improved tolerance to severe-intensity exercise (399 ± 81 vs. 438 ± 110 sec; $p < 0.05$). Similarly, changes in blood lactate concentration differed between the two experimental conditions (7.0 ± 2.0 vs. 8.3 ± 2.4 mmol/L for placebo and phosphodiesterase-5 inhibition, respectively; $p < 0.05$).

CONCLUSION: Our findings indicate that acute administration of a phosphodiesterase-5 inhibitor, tadalafil, improved exercise tolerance without affecting the physiological responses to submaximal exercise in humans. This ergogenicity is possibly associated with the augmented activation of anaerobic sources of energy by the skeletal muscles mediated through the NO/CGMP signaling pathway.

MARKED PLASMA VOLUME EXPANSION WITHOUT TOTAL HEMOGLOBIN MASS CHANGES FOLLOWING A 330-KM EXTREME MOUNTAIN ULTRAMARATHON

KRUMM, B., RABERIN, A., CITHERLET, T., TAGLIAPIETRA, G., FAISS, R., DEBEVEC, T., GIARDINI, G., MILLET, G.P.
UNIVERSITY OF LAUSANNE

INTRODUCTION: Mountain ultramarathon (MUM) represents extreme physiological and environmental stress for the human body. In this context, blood volume changes might play a pivotal role in overall homeostasis. In contrast to shorter distances (e.g., marathons), a plasma volume (PV) expansion has previously been reported following ultramarathon distances. Nevertheless, reduced neuromuscular fatigue or muscle inflammation was interestingly observed after 330 km compared to a 177-km MUM, suggesting distance-specific effects. To test the hypothesis of a substantial rise in both hemolysis and PV following MUM, this study investigated select hematological changes following a 330-km MUM.

METHODS: Thirteen healthy participants (42 ± 7 years; 175 ± 8 cm; 68 ± 10 kg) completed a 330-km MUM (Tor des Géants). Total hemoglobin mass (Hbmass), total blood volume (BV), red blood cell volume (RBCV), and PV were determined before and immediately after the race by an optimized carbon monoxide (CO)-rebreathing method using a fully automated instrument (OpCo, Detalo Instruments). Blood viscosity was measured at different speeds (11.25, 22.5, 45, 90, and 225 s-1) at native and corrected (40%) Hematocrit (Hct) using a cone/plate viscometer (Brookfield DVII, Brookfield Engineering Labs).

RESULTS: The participants' average finishing time was 118 ± 19 h. A significant change in PV (+590 ± 0.38 mL [+17.7%]; $p < 0.001$), BV (+0.55 ± 0.42 L [+9.5%]; $p < 0.001$), and Hct (-4.1 ± 4.2%; $p = 0.004$) was noted after the race. A decrease in native viscosity was observed at all speeds ($p < 0.001$), although only the 45 s-1 speed was affected by the corrected viscosity (-1.08 ± 1.78 cP; $p = 0.002$). No significant differences were observed for absolute Hbmass (802 ± 102 vs. 833 ± 111 g; $p = 0.09$), relative Hbmass (11.8 ± 1.1 vs. 12.2 ± 1.0 g·kg-1; $p = 0.14$), nor RBCV (2.5 ± 0.3 vs. 2.4 ± 0.3 L; $p = 0.5$).

CONCLUSION: In the present study, a comparable increase in PV (+17.7%) and related BV (+9.5%) was noted to what had been observed previously on a 171-km MUM. Generally explained by sodium retention coupled with the exercise-induced inflammatory response, this transient hypervolemia does therefore not seem to be more severe with increasing distance. In addition, although the drop in Hct largely explains the decreased blood viscosity, the reduction in the corrected viscosity at intermediate speeds suggests slight changes in RBC behavior. However, in contrast to expectations suggesting a decreased Hbmass due to hemolytic effects, a trend towards increased Hbmass (+31 g) was observed. While probably explained by splenic contractions or enhanced CO diffusion to intramuscular myoglobin, an actual stimulation of erythropoiesis during the race cannot be completely excluded. This study provides further insights into the physiological mechanisms that occur during one of the world's most challenging MUM.

RUNNING FOR YOUR LIFE: METABOLIC EFFECTS OF A 160.9/230 KM NON-STOP ULTRAMARATHON RACE ON BODY COMPOSITION, INFLAMMATION, HEMORHEOLOGY, HEART FUNCTION, AND NUTRITIONAL PARAMETERS

BIZJAK, D.A., SCHULZ, S., JOHN, L., SCHELLENBERG, J., BIZJAK, R., WITZEL, J., VELDER, S., KOSTOV, T., DIEL, P., GRAU, M.
UNIVERSITY HOSPITAL ULM

INTRODUCTION: Moderate endurance exercise leads to an improvement in cardiovascular performance, stress resilience, and blood function. However, the influence of chronic endurance exercise over several hours or days is still largely un-

clear. We examined the influence of a non-stop 160.9/230 km ultramarathon on body composition, hemorheology, stress response, cardiac adaptations and nutrition parameters.

METHODS: Blood samples were drawn before (pre) and after the race (post) and analyzed for hematological and hemorheological variables as well as ghrelin, insulin, irisin, glucagon, cortisol, kynurenine, neopterin, and total antioxidant capacity. Additional measurements included heart function by echocardiography, nutrition questionnaires, continuous glucose measurements and body impedance analyses. A possible influence of different beverages on the release of bacterial endotoxin as possible monitoring tool for regeneration was also assessed.

RESULTS: Of the 28 included ultra-runners (7f/21m), 16 participants dropped out during the race. The remaining 12 finishers (2f/10m) showed depletion of antioxidative capacities and increased inflammation/stress (white blood cells/neopterin/cortisol), while energy metabolism (insulin/glucagon/ghrelin) remained unchanged despite a high negative energy balance (6000-9000 kcal). Free fat mass, protein, and mineral content decreased. Red blood cell (RBC) deformability increased while osmolality in both the hypotonic and hypertonic region and viscosity declined post-race. RBC nitrite metabolism showed different responses and adaptations depending on race distance. Echocardiography revealed a lower stroke volume, left end diastolic volume, and ejection fraction post-race. Endotoxic values were lower 3 hours post-race if beverages without sugar or together with polyphenols were ingested.

CONCLUSION: Optimizing nutrition (high-density protein-rich diet) during the race may attenuate the observed catabolic and inflammatory effects induced by ultramarathon running. Monitoring of hematological and hemorheological changes may reveal RBC mechanistic adaptions for counteracting molecular stress during this orthopedic and cardiovascular demanding long-term endurance competition. As a rapidly growing discipline, new strategies for health prevention and extensive monitoring are needed to optimize the athletes' performance.

COMPARATIVE ANALYSIS OF MATCH DURATION AND FOOTBALLERS RUNNING PERFORMANCE: 2022 FIFA WORLD CUP VS. 2018 FIFA WORLD CUP

ZHAI, Y., WANG, J.
TONGJI UNIVERSITY

INTRODUCTION: This study aims to explore differences in match duration and player running between the 2022 FIFA World Cup and the 2018 FIFA World Cup , investigate the relationship between match duration and running distance, and discuss the implications of the 2022 extra time reform on future football-specific fitness training.

METHODS: Video replays of 64 matches from the 2018 and 2022 FIFA World Cups were meticulously analyzed. Match time data for the first and second halves, as well as extra time, were recorded based on referees whistle signals. Running data for each team in both tournaments were obtained from FIFAs official website and categorized into walking (0-7km/h), low-speed running (7-15km/h), medium-speed running (15-20km/h), high-speed running (20-25km/h), and sprint running (25km/h+). Differential comparisons of time and running data were conducted using IBM SPSS Statistics 19, and Pearson correlation analyses were performed between time and running data.

RESULTS: Match Duration: The average match duration per match was significantly higher in the 2022 FIFA World Cup compared to the 2018 FIFA World Cup (103.90±9.219 vs. 99.45±8.702 minutes, $p<0.05$, Cohens d=0.50). The average effective playing time per match in 2022 was 58 minutes 04 seconds, higher than 55 minutes 09 seconds in 2018. Statistically significant differences were observed in match durations for the first and second halves, while overtime duration showed no statistical significance. Differences in match durations were significant in the group stage matches but not in the knockout stage.

Footballers Running Performance: In terms of team average total distance run per match, 2022 was significantly higher than 2018 (114603±433.16 vs 104662±376.17 meters, $p<0.05$, Cohens d=24.51). Similarly, team average per-match high-intensity running distance (speed ≥20km/h)(9170.87±821.38 vs 7554.37±574.35 m , $p<0.05$,Cohens d=2.28)and distance per sprint (speed ≥25km/h)(2389.94±302.61 vs 2026.03±230.99 m , $p<0.05$,Cohens d=1.35) were significantly higher in 2022 compared to 2018. The team average number of sprints per match in 2022 was also significantly higher than in 2018(528±40 vs 330±24 , $p<0.05$,Cohens d=6.00).

Correlation Analysis: In 2022, there was a very large positive correlation between match duration and total team distance run per match ($r=0.834$, $p<0.05$), a moderate positive correlation for both high-intensity running ($r=0.477$, $p<0.05$) and sprinting distance run ($r=0.403$, $p<0.01$), and a large positive correlation for the number of sprints ($r=0.570$, $p<0.05$), all statistically significant.

CONCLUSION: The reform of extra time regulations in football matches significantly increased match duration in the 2022 FIFA World Cup compared to the 2018 FIFA World Cup. Players were required to cover longer distances with higher intensity and engage in more sprints during matches, highlighting increased demands on players physical fitness, especially anaerobic endurance.

MODELLING OF THE VO2/PO RELATIONSHIP DURING RAMP VS. CONSTANT WORK RATE EXERCISE IN HEALTHY ACTIVE INDIVIDUALS

STUER, L., MUCCI, P., BOONE, J., CAEN, K.
GHENT UNIVERSITY

INTRODUCTION: Introduction: Ramp incremental (RI) tests are frequently used to prescribe exercise intensities. However, the dissociation that exists between the RI versus constant work rate (CWR) VO2/power output (PO) relationship complicates the translation from RI PO to CWR PO [1]. The current translation strategies assume a linear development of the CWR VO2/PO relationship in the heavy domain [2, 3]. Hence, the main purpose of this study was to mathematically model this relationship within the heavy and severe intensity domains to analyse whether the loss of mechanical efficiency truly develops linearly. A second aim was to assess the reliability of parameters used in the existing translation strategies (i.e., baseline VO2, mean response time (MRT), and slopes of the RI VO2/PO relationship).

METHODS: Methods: 14 healthy young participants (7 men and 7 women; 22 ± 2 yr; 44.4 ± 7.4 mL • min-1 • kg-1) performed a maximal RI test and a series of CWR tests with intervals of 10 W (starting from GET up to VO2peak) on separate days. All tests were conducted on a cycle ergometer. For reliability purposes, every CWR test was preceded by a linear increase in PO (similar to the RI test) from baseline cycling until target PO was reached. The individual RI VO2/PO relationship was modeled using two linear regression lines (i.e., one portion below and one portion above GET). The individual CWR VO2/PO relationship was modeled linearly and the slope was calculated both for the heavy domain only and for the heavy and severe domain. To assess test-retest reliability, coefficients of variance (CV) were calculated.

RESULTS: Results: The CWR VO2/PO relationship in the heavy and severe domains was strongly linear (R^2: 0.92 ± 0.04 – 0.94 ± 0.03). The slopes above GET from the CWR VO2/PO relationship (11.1 ± 1.1 – 11.6 ± 1.0 0 mL • min-1 • W-1) were significantly higher compared to the slope above GET from the RI VO2/PO relationship (8.7 ± 0.9 mL • min-1 • W-1) ($p < 0.001$). CV for baseline VO2 was 4.3 ± 0.8%. CV for the slopes, below and above GET, from the RI VO2/PO relationship were respectively 8.9 ± 6% and 19.1 ± 10.5% . CV for MRT was 28.6 ± 9.8%.

CONCLUSION: Conclusions: This study confirmed that the loss of mechanical efficiency develops linearly in the heavy and severe intensity domains. The reliability of the parameters used in the current correction strategies ranged from acceptable to very good. For both reasons, applying such translation strategies is justified.

RELIABILITY OF CRITICAL VELOCITY DURING STANDARDIZED TREADMILL ENDURANCE RUNNING

ISAIAH, R., PASTELLIDOU, E., JOHNSTON, L., WILSON, J., PRICE, K., PENPRAZE, V., KEMI, O.
UNIVERSITY OF GLASGOW

INTRODUCTION: Performance during continuous high-intensity exercise is determined by the hyperbolic speed-tolerable duration (S-tLIM) relationship, defined as the limit of tolerance by the asymptote for critical velocity (CV), the metabolic equivalent oxygen uptake (VO2) and the curvature constant D' that indicates the amount of work (duration) that can be achieved above CV. The lower boundary of CV thereby demarcates between heavy and severe exercise intensities, and the relationship is therefore useful for monitoring exercise capacity, for pacing, and for accurate intensity setting in the severe exercise domain. However, a series of constant load time to exhaustion (TTE) performance tests are required to establish S-tLIM in individuals, which introduces a source of variability, but reproducibility of S-tLIM remains unknown.

AIM:

This study therefore investigated the test-retest reproducibility of CV in healthy controls (non-runners) and club-level runners.

METHODS: Healthy male participants volunteered; 11 non-runners and 10 active runners (running training >5/week). They performed incremental exercise tests (IET) to determine VO2max and Vmax (maximal aerobic speed). Then, at least 4 individualised constant load TTE tests (range 3-15 mins), each separated by at least 48 hours, were performed to establish S-tLIM within acceptable modelling limits. These were then retested to establish test-retest reproducibility.

RESULTS: Runners presented with 15-20% increased VO2max and Vmax and 25% increased CV vs controls. On completion of the constant load TTE tests and after confirming tests were performed to true exhaustion by comparing VO2max obtained during IET to VO2 obtained during TTE tests (all P>0.05), the V-t and V-1/t relationships were plotted. From test and retests, runners presented with CV 14.4±0.4 km/h and 14.6±0.4 km/h (P=0.267, not different) and D' 903.3±112.1 m and 1010.5±95.3 m (P=0.116, not different), while controls presented with CV 11.2±0.6 km/h and 11.8± 0.6 km/h (P=0.003, different) and D' 1269.0±117.6 m and 963.8±103.8 m (P=0.002, different). The magnitude of test-retest difference is smaller in runners vs controls, and in runners, 8/10 achieve test-retest agreement within 5%, whereas only 5/11 achieve this in controls, whereas Bland-Altman analysis also indicated greater test-retest bias in controls vs runners.

CONCLUSION: Protocols for determining CV and D' were more reproducible for runners but not controls, in which significant . Therefore, the S-tLIM relationship obtained during treadmill exercise should be used with consideration in non-

running cohorts, whereas in athletes accustomed to the exercise mode, the S-tLIM presents an accurate performance-based indicator of functional exercise capacity in the severe intensity domain that may be applied for pacing and intensity control.

EFFECTS OF SPIKE MIDSOLE FOAM AND BENDING STIFFNESS ON RUNNING ECONOMY AND MIDDLE-DISTANCE PERFORMANCE

RODRIGO CARRANZA, V., MUÑOZ DE LA CRUZ, V., GONZÁLEZ-MOHÍNO, F., RODRÍGUEZ-BARBERO, S., GONZÁLEZ-RAVÉ, J.M., HOOGKAMER, W.

1 SPORTS PERFORMANCE RESEARCH GROUP , UNIVERSITY OF CASTILLA-LA MANCHA, TOLEDO, SPAIN. 2 INTEGRATIVE LOCOMOTION LABORATORY, DEPARTMENT OF KINESIOLOGY, UNIVERSITY OF MASSACHUSETTS, AMHERST, USA

INTRODUCTION: Research into the benefits of different advance footwear technologies (AFT) spikes on middle/long distance track performance is lacking. This study aimed to examine the influence of different spikes technologies on running economy (RE) and middle-distance performance measures in trained runners.

METHODS: Sixteen male trained runners completed four different visits on a 400 m outdoor track, running in three different spikes conditions. We compared a traditional EVA midsole spike (Control) with a modern midsole foam (PEBA) spike and a spike with a PEBA midsole and a carbon-fiber plate (PEBA+Plate). During the first three visits, participants performed 6x200 m at self-perceived 800 m race pace wearing each condition twice in a mirrored order (a-b-c-c-b-a) separated by 8 min rest between trials. Subsequently, they performed a 3,000 m time trial using one of the three shoe condition, in each visit. During visit 4, participants completed 6x4 min efforts at 18 km/h in each condition to assess RE (W/kg).

RESULTS: The main effect for spike condition was significant for the runs at self-perceived 800 m pace ($p<0.001$; $\eta 2 =0.438$), the 3,000 m time trial ($p=0.013$; $\eta 2 =0.342$) and RE ($p<0.001$; $\eta 2 =0.694$). At 800 m race pace, PEBA+Plate (6.63±0.36 m/s; $p<0.001$) resulted in 2.8% faster 200 m runs compared to Control (6.45±0.36 m/s), while PEBA (6.53±0.45 m/s) and Control were similar. The 3,000 m speed improved in the PEBA (5.79±0.23 m/s; $p=0.034$; 1.0%) and PEBA+Plate conditions (5.87±0.37 m/s; $p=0.032$; 2.4%) compared to Control (5.73±0.29 m/s). RE improved significantly in the PEBA (20.25±1.79 W/kg; $p<0.001$; 5.1%) and PEBA+Plate conditions (20.47±1.43 W/kg; $p<0.001$; 4.0%) compared to Control (21.30±1.59 W/kg), without significant differences between the PEBA and PEBA+Plate conditions.

CONCLUSION: Our results suggest that AFT spikes with modern foams enhance running performance across middle- and long-distance events. However, at mid-distance speeds the PEBA+Plate technology performed better than Control, while modern foam alone (PEBA) did not significantly improve performance. This may be because when running at higher speeds, the optimal longitudinal bending stiffness of the shoe might be higher (1). However, for running at 18 km/h, RE improved similarly in both AFT spikes (PEBA and PEBA+Plate) compared to traditional EVA spikes. At sub-maximal speeds, differences may be mainly due to differences in midsole foam rather than in longitudinal bending stiffness (2).

INVESTIGATING THE APPLICATION OF SKATE-SECURED 3-D ACCELEROMETERS TO ASSESS ON-ICE PERFORMANCE AND THE ASSOCIATED RELATIONSHIPS WITH OFF-ICE PERFORMANCE METRICS IN COMPETITIVE YOUTH HOCKEY ATHLETES

TWIBLE, B., DALTON, B., MCNEIL, C.

UNIVERSITY OF BRITISH COLUMBIA - OKANAGAN

INTRODUCTION: The ability to rapidly generate muscle force (produce power) is a critical determinant of athletic performance. Recent technological progress provides opportunities for limb-specific assessment of neuromuscular parameters during training or competition, which can reveal inter-limb asymmetries (ILAs) that may limit functional capacity. Yet, due to difficulties with on-ice data collection, hockey athletes are an understudied population compared to other sporting groups. The purpose of this study was to explore the implementation of skate-secured 3-D accelerometers to assess on-ice performance, and to investigate the relationship between on- and off-ice performance metrics. We hypothesized that relationships would exist between on- and off-ice metrics, including ILAs, and that lower-limb ILA would be inversely related to skating performance.

METHODS: Seventeen participants (15.0 ± 1.2 years; seven females) completed two performance-based tasks to assess lower-limb function: a 30-m forward sprint (on-ice), and a vertical countermovement jump (CMJ) (off-ice). On-ice metrics of interest included mean stride power and total sprint time. The vertical CMJ was performed on a dual force plate system, and metrics of interest included peak jump height, relative peak force and power, relative braking rate of force develop-

ment, and impulse (braking and propulsive). Mean stride power, as well as CMJ impulse (braking and propulsive), force, and rate of force development were used to assess ILA. Linear regressions were performed to determine relationships between on- and off-ice variables.

RESULTS: An inverse relationship was found for mean stride power and skating sprint time ($R2 = 0.30$; $p = 0.02$). Positive relationships were detected between peak CMJ height and both mean stride power ($R2 = 0.37$; $p = 0.01$) and skating sprint time ($R2 = 0.75$; $p < 0.01$), as well as between peak CMJ relative power and both mean stride power ($R2 = 0.30$; $p = 0.02$) and skating sprint time ($R2 = 0.71$; $p < 0.01$). Regarding asymmetries, there was a positive relationship between ILAs for CMJ rate of force development and mean stride power ($R2 = 0.31$; $p = 0.02$); however, no other relationships between off-ice and on-ice ILA measures were significant ($p \geq 0.32$). Additionally, no on- or off-ice measure of ILA related to skating sprint time ($p \geq 0.09$).

CONCLUSION: In summary, skate-secured 3-D accelerometers allow assessment of limb-specific on-ice parameters that are important for skating performance. Although a relationship between on- and off-ice performance was identified, the presence of on- or off-ice ILAs may not be important for short-term power production.

EXPLORING BREATH-VOLATILE ORGANIC COMPOUNDS AS NON-INVASIVE BIOMARKERS TO PREDICT CARDIORESPIRATORY FITNESS – PRELIMINARY DATA FROM THE PREDICT-FIT PROJECT

TEIXEIRA, E., SILVA, G., RUFO, J.

RESEARCH CENTER IN PHYSICAL ACTIVITY, HEALTH AND LEISURE, FACULTY OF SPORTS, UNIVERSITY OF PORTO, PORTUGAL

INTRODUCTION: Cardiorespiratory fitness (CRF) is a fundamental exercise-related factor and a well-established vital sign (1). Maximal oxygen consumption (VO2max), the CRF gold-standard assessment, is cumbersome and imposes significant participant stress, limiting testing frequency. Expedient and safer CRF assessment methods are imperative to exercise and health professionals. Recent studies analysing the exhaled breath (breathomics) volatile organic compounds (VOCs), which differ depending on health status (2), may pose such an alternative. Breathomics is conducted through the analysis of exhaled VOCs with electronic nose systems (eNose), which are capable of discerning distinct compound profiles, holding predictive value for CRF assessment. This study investigated the use of breathomics to identify individuals with directly measured peak VO2max (VO2) above or below the age- and gender-specific estimated oxygen consumption (eVO2) (3).

METHODS: Breathomics of sixty-five participants (age: 34.8±11.5 years, 86% males) were performed by collecting the individuals' VOCs while fasting for at least 3 hours, following a 2-minute preliminary breathing procedure through an A2 filter. VOCs were collected in Tedlar bags and analyzed by Cyranose 320 eNose. Then, participants performed a VO2max test (Quark, COSMED), cycling nearly 15 minutes during progressive intensity levels until exhaustion, to determine VO2. Participants were dichotomized based on their eVO2 for analytical purposes.

RESULTS: Recursive partitioning regression identified twenty participants with a distinct breathomics profile (DBP) defined by eNose sensors S4 and S26. Post-hoc analysis showed a significantly higher proportion of individuals who did not meet eVO2 criteria when having the DBP (66.6%, $p<0.001$). In addition, a t-student test revealed significant differences in mean VO2 values between groups, being lower in individuals with the DBP (40.8±6.0 vs 46.8±11.1, $p=0.027$). Logistic regression showed a significant association between having the DBP and failing the eVO2 criteria, even when adjusted for exercise volume and the number of fasting hours (OR 95%, CI = 17.5 [4.2, 97.3], $p<0.001$). This model identified individuals who failed to meet the eVO2 criteria with a sensitivity of 75% and a specificity of 95% (AUC = 0.87).

CONCLUSION: Individuals with DBP were, on average, 17.5 times more likely to have VO2 values lower than eVO2. Further analysis of the breathomics profile using mass spectrometry methods is needed to identify the specific discriminant VOCs. While further research is warranted, breathomics holds promise for predicting VO2 outcomes, potentially fostering continuous CRF monitoring both in exercise and health-related scenarios.

MECHANICAL PROPERTIES OF DIFFERENT TYPES OF TENNIS COURT SURFACES

COLINO, E., GARCÍA-UNANUE, J., FELIPE, J.L., QUINTANA-GARCÍA-MILLA, I.

UNIVERSIDAD FRANCISCO DE VITORIA

INTRODUCTION: Tennis is one of the sports in which the surface plays an important role in performance and injury risk. Professional players face an extensive competition calendar in which they must adapt to different types of surfaces. However, unlike other sports, tennis lacks standards that regulate surface properties affecting athlete-surface interaction on each type of surface. The objective of this study was to evaluate shock absorption (SA), vertical deformation (VD), energy restitution (ER) and slip resistance (SR) in different types of tennis surfaces, compare them with each other and look for correlations between variables.

METHODS: Thirty-six tennis courts (12 hard court, 16 clay, 8 artificial grass) were evaluated. SA, VD and ER were assessed using the apparatus (advanced artificial athlete) and test method described in the FIFA Handbook of Test Methods, and SR was measured using a pendulum device and conducted according to EN 16165:2021.

RESULTS: All variables differ significantly between surfaces (p<.001). SA (1.1±0.5% to 13.9±3.4%) and VD (0.02±0.04mm to 1.07±0.19mm) were lower on hard court compared to clay and artificial grass; ER (72.5±4.7% to 89.9±1.5%) evolved in the opposite way; and SR (in PTV) was lower on clay (53.6±2.5) compared to grass (61.4±1.3) and hard court (66.6±1.1). No significant correlations between variables were identified in hard court. However, both clay and artificial grass showed a significant positive correlation (p<.001) between SA and VD (0.872 and 0.947, respectively), and a significant negative correlation (p<.001) between SA and ER (-0.807 and -0.981, respectively). Also, significant negative correlations were found between VD and ER both in clay (-0.802; p<.001) and artificial grass surfaces (-0.890; p<0.01). As for the SR, only a significant negative correlation with VD in artificial grass (-0.715; p<0.05) was identified.

CONCLUSION: These results suggest that more compliant artificial grass surfaces may provide reduced friction in the shoe-surface interface, and that the frictional properties of clay and hard courts may be related to other variables other than SA, VD or ER of the surface (e.g., humidity or particle size of the clay). This study is the first one to describe the mechanical properties of tennis courts as is usually done in other sport surfaces when the athlete-surface interaction is assessed. These data reveal the disparities among surfaces and may contribute to laying out the foundations of future regulations aimed to assess and control the mechanical properties of tennis surfaces. These regulations would allow facility managers and competition organisers to carry out a more systematic and exhaustive control of the surfaces functionality; would give court constructors, suppliers, and end-users a common language to describe different products; and, most importantly, would contribute to reducing the risk of injury due to the state of the surface and to preserve safety and performance of tennis players.

DETAILED ANALYSIS OF MOVEMENTS DURING WHEELCHAIR TENNIS MATCHES

DEVES, M., SAURET, C.2, HAYS, A.3, FAUPIN, A.1

JAP2S <1>, CERAH <2>, HIPE <3>, FFT <4>

INTRODUCTION: Wheelchair tennis (WT) involves intermittent aerobic activity with multidirectional movements, including high-speed linear and rotational actions, and rapid accelerations [1]. Quantifying physical loading during matches is crucial for trainers to develop effective training programs. The use of onboard sensors, particularly inertial sensors, has become common for studying wheelchair movements, enabling detailed descriptions of specific movements in WT [2]. However, theres a lack of studies focusing on precise quantification of physical load during WT matches. Generic training programs may lead to poor performance and injuries due to interindividual variability within the wheelchair sports population [3]. Our study aims to propose a method for characterizing and describing locomotor activities during WT matches.

METHODS: Nine French WT international players, comprising six men and three women, participated in our study. We recorded thirteen matches, totaling 26 sets and 213 games. Athletes utilized their own wheelchairs equipped with Xsens Inertial Measurement Units (IMUs) on the wheels and frame, enabling kinematic data collection during all games. Time series data of linear velocity, rotation velocity and radius of curvature were processed using a PAA-SAX method for data reduction and symbolic representation. A final logical pattern search on these signals identified different locomotion tasks.

RESULTS: Across all recorded matches, players spend an average of 25 ± 14% of the time in a static state, 41 ± 10% of the time moving in a straight line, and 24 ± 9% of the time executing wide curves. Movement characteristics and intensity are measured through segmentation. During games, players engage in various types of straight lines: 433 ± 152 within 0 to 3 meters, 154 ± 54 within 3 to 8 meters, and 55 ± 22 longer than 8 meters, with respective intensities of 4 ± 3%, 7 ± 4%, and 3 ± 4% at very high intensity (> 75% of maximal acceleration). They also execute wide turns (715 ± 222) and tight turns (363 ± 82) during the match. Among wide turns, 41 ± 5% are at high rotational velocity (>= 120°/s), with an average rotation of 84.47 ± 67.65°, covering 2.14 ± 2.02 meters. Among tight turns, 66 ± 5% are executed at high rotational velocity (>= 120°/s), with an average rotation of 78.93 ± 48.38°, covering 0.55 ± 0.36 meters.

CONCLUSION: The employed method confirms our initial hypothesis by enabling quick and simplified visualization of entire games, sets, or matches. Subsequently, this method allows us to characterize different types of activities to describe the intensity of play. Physical trainers can use this processing method to determine the external load of the activity and adapt their training accordingly. Future studies could be designed to compare the intensity of matches at different level.

OP-PN32 Hormonal Biology II

BRAIN-DERIVED NEUROTROPIC FACTOR RESPONSES DURING MULTI-STRESS MILITARY TRAINING

NYKANEN, T., OJANEN, T., KYRÖLÄINEN, H.

FINNISH DEFENCE FORCES

INTRODUCTION: In addition to a well-documented role in neurodegenerative diseases, brain-derived neurotropic factor (BDNF) has also been studied in military environments, where mental stress, energy and sleep deficit, and prolonged physical activity are continuous and fluctuating stress factors (Beckner et al. 2022). Reduction in body mass and remarkable hormonal responses are often observed simultaneously in this type of trainings (Ojanen et al. 2023). BDNF concentration typically decreases in strenuous environments, but the function of this neurotrophin is not clearly understood. Thus,

the purpose of this study was to a) describe BDNF responses in multi-stress military training, b) examine associations between BDNF, body composition and biomarkers, and c) study the effect of 36 hours' recovery on these outcomes during training.

METHODS: Two groups of male soldiers were studied: FEX (n=42, 19.5 ± 0.8 years, 179 ± 6 cm, 74.4 ± 10.8 kg) had continuous winter field training with energy and sleep deficit, while REC (n=26, 19.7 ± 1.2, 181 ± 6 cm, 78,2 ± 9.6 kg) had 36-hours active recovery phase in the middle of training (days 6 to 8). Body composition was measured via bioimpedance, and blood samples for BDNF and biomarkers (testosterone, cortisol, IGF-1, leptin, ghrelin, adrenalin, noradrenalin, prolactin, sex hormone binding protein) were collected at days 1, 6, 8, 10 during training. Linear mixed model was used for evaluating main effects and interactions between time and group, and Spearman correlations with FDR adjustments for associations between BDNF, body composition and biomarkers. Statistical significance was set as $p<0.05$.

RESULTS: BDNF decreased in both groups during training and systematically lower BDNF values were found in the REC group compared to the FEX group (main effects with time $p<0.001$ and group $p=0.011$). No associations were found between BDNF, body composition or metabolic biomarkers at any time points, and further, changes in BDNF concentration did not associate with changes in body composition or biomarkers.

CONCLUSION: A decrease in BDNF levels was found during multi-stress military training in both groups, regardless of the active recovery period of the REC group. Higher initial body mass was observed in the REC group, but none of the body composition variables, or biomarkers, explained the systematic difference in BDNF levels observed in this data. Further research is needed to elucidate the role of BDNF in anabolic and catabolic processes in multi-stress military environments.

THE IMPACT OF TWO MODES OF EXERCISE OF THE SAME INTENSITY (ENDURANCE VS. COORDINATIVE) ON CORTISOL LEVELS

BUDDE, H.

MEDICAL SCHOOL HAMBURG

INTRODUCTION: Physical exercise interventions can cause neuroendocrine activation, which in turn increases salivary cortisol concentrations (Budde et al., 2015). We aimed to investigate the influence of different acute exercise interventions on cortisol levels. Here, we distinguished between a coordinative exercise and an endurance exercise. To our knowledge, there have been no studies to date on whether the hypothalamic-pituitary-adrenal (HPA) axis differ between an acute coordinative exercise and an acute endurance exercise of the same intensity and duration. The purpose of this study was to examine the effects of these two different acute physical stressors on cortisol levels, specifically focusing on an intraindividual comparison between an acute coordinative and acute endurance exercise.

METHODS: Sixty-one students between eighteen and thirty years of age were included in the study and completed first a coordinative exercise and seven days later an endurance exercise of the same intensity and length which was self set on the first day, with a mean heart rate of 75-80% max over a period of 15 min. To measure changes in HPA axis activity, saliva samples were collected before and 5 and 30 minutes after exercise. The exercise intensity was controlled individually on a heart rate (HR) monitor as was the Rate of Perceived Exertion (RPE) using the Borg Scale (Borg and Loellgen, 2001). The saliva was stored at -20C° and analyzed within the next month for cortisol.

RESULTS: The results showed that the coordination exercise (co) produced a higher cortisol release than the endurance exercise (en). While the mean intensity was: HR 143 and the RPE was 13.9 co vs. 13.8 en.

CONCLUSION: We argue that interventions such as a coordinative exercise require a higher cognitive component, which results in stronger cortisol release than an endurance exercise of the same intensity and length and RPE level. Neither the motor fitness level nor the physical activity level hat an impact on the cortisol secretion. Thus, the type of acute physical exercise would be a psychophysiological factor in determining the neuroendocrine stress response and may be of interest in further research to sufficiently elucidate the proximate mechanisms of the stress reactions from acute physical exercise. Until now these results could only be obtained when we observed a blunted cortisol awakening response (CAR) due to coordinative vs endurance training (Wegner et al., 2019).

PLASMA LEVELS OF ANABOLIC STEROID HORMONES FROM CAPILLARY BLOOD SAMPLING DURING THE MENSTRUAL CYCLE IN TRACK AND FIELD ATHLETES

SIPPL, J.1, KEILER, A.M.2,3, KRUMBHOLZ, A.2, BÜTHE, E.1, PILZ, M.1, PLATEN, P.1

1 SPORTS MEDICINE AND SPORTS NUTRITION, RUHR UNIVERSITY BOCHUM, 2 INSTITUTE OF DOPING ANALYSIS AND SPORTS BIOCHEMISTRY DRESDEN , KREISCHA, 3 ENVIRONMENTAL MONITORING & ENDOCRINOLOGY, TU DRESDEN

INTRODUCTION: The menstrual cycle (MC) is characterized by fluctuations of the sex steroids estrogen and progesterone. However, the cyclic fluctuations of anabolic steroid hormones such as testosterone and androstenedione, which are secreted from both ovaries and the adrenal cortex, and the influence of hormonal oral contraception (OC) are largely unknown in elite female athletes. As the phases of MC might influence athletic performance and strength training adaptations1, a deeper understanding of the secretion and metabolism of anabolic sex steroid hormones through the MC is needed. The present study aimed to investigate the plasma levels of these hormones using capillary blood sampling as a new sampling method during MC in elite athletes with and without OC (wOC/noOC).

METHODS: 22 elite track and field athletes participated in a longitudinal study of MC monitoring in sports. 12 athletes with normal MC (n=19 cycles) and 5 athletes with OC (n=10 cycles) (26±6 y, 172±5 cm, 68±7 kg) were included in the analysis. In addition to the progesterone measurement, the intravaginal body temperature was measured daily for 24 hours to determine ovulation. Further, athletes collected capillary EDTA blood before training each Monday, Wednesday, and Friday. Plasma steroid hormones were analyzed by LC-MS/MS. Linear mixed models were used to compare testosterone (T) and androstenedione (A) during different phases of MC/noOC (7-phases: menstruation, mid and late follicular phase (FP), ovulation, and early, mid and late luteal phase (LP) and wOC (7-"phases": 28 days/ 7). The average of T and A was used for statistical comparison between noOC and wOC using the Mann-Whitney-U test.

RESULTS: In noOC plasma levels of T and A were significantly higher during ovulation compared to menstruation (T: ovulation: 0,44±0.23 ng/ml; menstruation: 0.30±0.12 ng/ml; 95% CI [0.03 0.18], p=0.032; A: ovulation: 1.45±0.65 ng/ml; menstruation: 0.88±0.38 ng/ml; 95% CI [0.22 0.68], p<0.001). In addition, A differed between ovulation and mid FP, late FP, mid LP, and late LP (ANOVA summary, p=0.012). Further, steroid hormone concentrations in wOC did not differ between the respective "phases". Median A concentration was higher in noOC compared wOC (noOC: 0.84 (0.6, 1.06) ng/ml; wOC: 0.97 (0.79, 1.29) ng/ml; 95% CI [-0.27 -0.10], p<0.001), while median T did not differ between groups.

CONCLUSION: In regular menstruating athletes plasma T concentrations were about 45% and A concentrations about 60 % higher around ovulation compared to menstruation. These findings of higher anabolic steroid hormone concentrations around ovulation support the rationale for periodizing training to MC. Results between athletes without and with OC are contradictory concerning T and A. Hormonal changes in the MC were highly variable and require individual analysis and interpretation. This project was funded with research funds from the Federal Institute for Sports Science based on a decision by the German Bundestag.

CHANGES IN ENDOGENOUS ANDROGEN HORMONE PROFILE AFTER ~8-WEEKS OF MODERATE INTENSITY ENDURANCE TRAINING IN NATURALLY MENSTRUATING AND MONOPHASIC ORAL CONTRACEPTIVE USING FEMALES

SALMI, V., LEHTI, M.1, HACKNEY, A.C.2, IHALAINEN, J.K.1,3, MIKKONEN, R.1

1 UNIVERSITY OF JYVÄSKYLÄ, JYVÄSKYLÄ, FINLAND; 2 UNIVERSITY OF NORTH CAROLINA, CHAPEL HILL, NORTH CAROLINA, USA; 3 FINNISH INSTITUTE OF HIGH PERFORMANCE SPORT KIHU, JYVÄSKYLÄ, FINLAND

INTRODUCTION: Concentrations of sex steroid hormones, including androgens, fluctuate during the menstrual cycle (MC) and with hormonal contraceptive (HC) use [1]. However, research regarding the effects of chronic endurance training on basal androgen concentrations in females is limited. Therefore, we examined changes in androgen concentrations after ~8-week of a moderate intensity endurance training program (MIET).

METHODS: Forty-four (tier 1) [2], naturally menstruating females (NM) [3] (length of MC 28 ± 4 d, age 30 ± 4 y, height 1.66 ± 0.05 m, weight 68.1 ± 10.8 kg, fat percentage 33.7 ± 8.3 %, and VO2max 38.4 ± 5.3 ml·kg-1·min-1) and 14 (tier 1) monophasic combined ethinyl estradiol-progestin containing oral contraceptive using females (OC) (age 27 ± 4 y, height 1.69 ± 0.06 m, weight 69.2 ± 5.9 kg, fat percentage 35.3 ± 5.1 %, and VO2max 39.0 ± 3.4 ml·kg-1·min-1) performed ~8-week MIET consisting of two MCs in NM and two 28-day HC "cycles" in OC. Prescribed training volume and intensity were the same in both groups and followed global exercise recommendations. Exercise included walking/running at 60–75 % of maximum heart rate. Fasting blood samples were collected before (PRE) and after (POST) MIET. In NM, samples were collected after the onset of bleeding between days 1–5 of the MC in the early follicular phase (FP) and 4–8 days after a positive ovulation test in the mid-luteal phase (LP). In OC, samples were collected between days 2–9 in the beginning of the active phase (i.e. pill taking days) and between days 2–6 of the inactive phase (i.e. pill free days). Estradiol (E2), progesterone (P4), total testosterone (tT), free testosterone (fT), dihydrotestosterone (DHT), androstenedione (A4), sex hormone-binding globulin (SHBG), dehydroepiandrosterone (DHEA) and its sulphate (DHEA-S) were analyzed from serum. Statistical analyses were conducted using generalized estimating equations.

RESULTS: Ovulation was detected in 89 % of participants during the first MC and in 82 % of participants during the second MC of the ~8-week MIET. In NM, serum concentrations of fT were significantly lower at POST compared to PRE at FP (B = -0.37, p = 0.043). Concentrations of DHEA-S were significantly lower at POST compared to PRE at LP (B = -0.35, p = 0.029). In OC, concentrations of DHT were significantly lower at POST compared to PRE at the inactive phase (B = -89.25, p =

0.045). Concentrations of other androgens, as well as concentrations of E2, P4 and SHBG remained unchanged in both groups.

CONCLUSION: Our findings suggest that chronic endurance training decreases androgen concentrations without concurrent changes in E2 and P4 both in naturally menstruating and monophasic combined oral contraceptive using females. However, the training induced reductions in specific androgenic hormones varied between NM and OC females.

ANGIOGENIC T-CELL NUMBER AND TRANSCRIPTOMIC CHANGES WITH ACUTE EXERCISE

ROSS, M., NIEMIRO, G., SMITH, K., BAKER, F., ZUNIGA, T., DIAK, D., SECKELER, M., KATSANIS, E., SIMPSON, R.

HERIOT-WATT UNIVERSITY

INTRODUCTION: CD31+ T-cells are a highly vasculogenic T-cell phenotype and have demonstrated potent angiogenic capabilities, such as containing elevated VEGF-A content, promoting blood flow recovery in a hindlimb ischaemia mouse model and being essential for optimal endothelial progenitor cell growth. One mechanism by which exercise may promote tissue angiogenesis and vascular repair may be through promoting angiogenic T-cell (TANG) mobilisation, resulting in exposure of these TANG cells to the endothelium. These cells are known to ingress into the circulation in response to exercise, but new technologies, such as single cell sequencing, can provide some insight into transcriptomic changes, which may underpin any upregulation of angiogenic functions.

METHODS: Ten healthy, non-smoking, physically active participants (26 ± 5 years, 171.2 ± 12.3cm, 66.9 ± 11.9kg) underwent a 30-minute cycling exercise bout at an intensity 15% above the pre-determined lactate threshold. Peripheral blood samples were taken by cannulation before exercise (PRE) and in the final minute prior to the completion of the exercise bout (POST). Peripheral blood mononuclear cells (PBMC) were isolated from whole blood using density gradient centrifugation and T-cells quantified using flow cytometry.

CD31+ T-cells underwent single cell sequencing using 10X Genomics platform. 5' RNA whole transcriptome libraries were generated using the 10xGenomics Chromium Next GEM Single Cell 5' reagents kit, following recommended guidelines. The gene expression libraries were quantified, normalized, pooled, and sequenced on an Illumina NextSeq500 sequencer. Differentially expressed genes were detected, with a log2 fold cutoff of 0. Gene set enrichment analysis was performed and annotated to both KEGG and GO terms.

T-cell number changes with exercise were analysed using paired T-tests. A p-value of <0.05 was deemed statistically significant.

RESULTS: Exercise resulted in a significant ingress of CD3+CD31+ (PRE: 268±176 cells·μL-1; POST: 437±345 cells·μL-1, p=0.027, t=2.631), driven by the changes in CD3+CD8+CD31+ (PRE: 130±73 cells·μL-1; POST: 221±165 cells·μL-1, p=0.024, t=2.708) subset, with no changes evident in the CD3+CD4+CD31+ (PRE: 123±115 cells·μL-1; POST: 186±197 cells·μL-1, p=0.091, t=1.896) T-cells. Whilst CD31+ T-cells demonstrate significantly greater expression of angiogenic genes (VEGFA, PIK3CB, MMP-9, THBS1) the acute bout did not stimulate changes in these pathways but did result in several transcriptomic changes in these CD31+ T-cells, with ribosomal biogenesis genes and pathways largely downregulated, and lymphocyte-mediated immune functional pathways upregulated.

CONCLUSION: CD31+ T-cells exhibit an angiogenic profile, and acute exercise non-preferentially mobilises CD31+ T-cells, which may expose the vasculature to their angiogenic supporting processes, but transcriptomic changes are largely immune-, rather than angiogenesis-related.

Oral Presentations

OP-MH28 Exercise Snacks

STAIR-CLIMBING "EXERCISE SNACKS" INTEGRATED INTO DAILY LIFE: A PROOF-OF-CONCEPT STUDY

RITTER, Y., SUN, X., SPINDLER, L., PFISTER, D., GRUBER, M., SCHWENK, M.

UNIVERSITY OF KONSTANZ

INTRODUCTION: Traditional exercise programs are rarely taken up due to insufficient time or motivation. The innovative approach Exercise snacking is a time-saving training method integrating short high-intensity training bouts (≤ 1 minute) (Francois et al., 2014). Previous studies used resource-intensive procedures with each exercise snack administered by a personal trainer (Jenkins et al., 2019) which may not be transferable into practical applications. This study aimed to test the proof-of-concept of a self-administered stair-climbing exercise snacking training program into daily routines.

METHODS: Eight physically inactive participants (6 females), aged 23–59 years took part in a 6-week pre-post intervention study. The participants were instructed to conduct 3 exercise snacks/day during 3 days of the week (9 snacks/week in total), monitored by a sports watch. After the intervention, the feasibility was tested with a Likert-scaled questionnaire

including acceptability, frequency of practice, adverse events, and safety, reported as median and interquartile range (IQR). For pre-post changes in anaerobic performance (countermovement jump test, stair climbing test) and aerobic performance (spiroergometry, maximal oxygen uptake VO2max, max load Wmax), descriptive statistics (mean and standard deviation) are given.

RESULTS: Participants rated the exercise snacking training "good" to "very good" (IQR: 1.25), indicating high acceptability. For frequency of practice, 9-16 exercise snacks/week were integrated into daily life with up to 120 stairs per exercise snack. No adverse events were reported. Participants perceived the exercise snacking program "safe" (IQR: 1). Pre-post changes for the countermovement jump test showed increased maximum height (Pre: 34.8±8.6cm, Post: 35.5±8.2cm), and maximum power (Pre: 2.5±1.0W, Post 2.7±2.5W), but reduced results for maximum force (Pre: 1.4±0.6kN, Post 1.3±0.4kN). The stair climbing test showed reduced time (Pre: 5.9±1.0sec, Post: 5.2±0.7sec). Pre-post changes for aerobic performance showed increased VO2max (Pre: 26.2±4.4ml/min/kg, Post: 26.8±5.2ml/min/kg) and for Wmax (Pre: 157.6±42.3W, Post: 171.1±47.4W).

CONCLUSION: Our results suggest that self-administered stair climbing exercise snacks are well accepted and feasible for integrating into daily life. Pre-post increases may indicate specific effects on anaerobic and aerobic performances but need to be verified in a randomized controlled trial.

RESISTANCE EXERCISE SNACKS: AN EFFECTIVE AND TIME-EFFICIENT METHOD TO IMPROVE MUSCLE MASS IN FEMALE UNIVERSITY EMPLOYEES

BRANDT, T., SCHWANDNER, C.T.L., SCHMIDT, A.

INSTITUTE OF SPORT SCIENCE, UNIVERSITY OF THE BUNDESWEHR MUNICH

INTRODUCTION: Although resistance training (RT) is essential to preserve musculoskeletal fitness and maintain a healthy, independent life into old age, few women perform RT. We investigated whether resistance exercise snacking (RES) could be an efficient training approach for the workplace health promotion (WHP) to minimize barriers for participation and facilitate RT in women in order to improve musculoskeletal fitness.

METHODS: This pilot-study followed a prospective, controlled intervention design. Female employees with sedentary occupations doing RT on less than 2 days/week before study participation were included. Participants self-selected for either intervention (IG) or control group (CG). While the IG [N = 15, mean age 42.1 (SD = 11.1) years] did 10 min of RES on working days for 12 weeks, the CG [N = 15, mean age 49.9 (SD = 9.7) years] was instructed to maintain their habitual physical activity. Primary endpoint was change in muscle mass. Secondary endpoint was change in maximum isometric strength. Balance, cardiovascular fitness, perceived health, and general life satisfaction was assessed for exploratory purpose. Measurements were taken before and after the intervention.

RESULTS: 12 participants of IG and 14 of CG completed the study. Muscle mass improved significantly more in the IG [+0.42 (SD = 0.54) kg] compared to the CG [−0.16 (SD = 0.51) kg] ($p = 0.01$, $\eta 2p = 0.24$). Strength did not change significantly between groups. Nevertheless, there was a trend for greater improvements in the IG compared to the CG for trunk extension, trunk flexion, and upper body push but not upper body pull. Regarding exploratory endpoints, no significant between-group changes were found. Despite their poor fitness, both groups perceived their health as good and had high life satisfaction before and after the intervention.

CONCLUSION: RES could be an effective approach for the WHP to promote RT in inactive women with sedentary occupations and improve their muscle mass.

FEASIBILITY OF TECHNOLOGY-ENABLED EXERCISE SNACKS IN A REAL-WORLD SETTING: A PROOF-OF-CONCEPT RANDOMIZED CLINICAL TRIAL.

BABIR, F., ISLAM, H.2, MCCREARY, S.2, VAZ, E.2, JUNG, M.2, SINGER, J.3, RICHARDS, D.1, GIBALA, M.1, LITTLE, J.2

1 MCMASTER UNIVERSITY, HAMILTON, ON, CANADA; 2 THE UNIVERSITY OF BRITISH COLUMBIA - OKANAGAN, KELOWNA, BC, CANADA; 3 THE UNIVERSITY OF BRITISH COLUMBIA, VANCOUVER, BC, CANADA

INTRODUCTION: Physical inactivity increases the risk of mortality and many chronic diseases. Regular physical activity confers health benefits that can include increased cardiorespiratory fitness (CRF), but many people are insufficiently active. Common cited barriers include a perceived lack of time and limited access to appropriate facilities and equipment. Exercise snacks (ES) are isolated bouts of vigorous effort lasting ≤1-min performed sporadically throughout the day. Small laboratory-based studies have shown that short-term ES interventions can increase CRF, but the intervention remains to be tested in real-world settings. This two-site pilot randomized controlled trial investigated the feasibility and preliminary efficacy of a 12-wk technology-enabled, remotely delivered ES intervention (ClinicalTrials.gov NCT05574426).

METHODS: Seventy-seven inactive adults aged 40-64 y (56 females/21 males; 54±6 y, body mass: 77±12 kg, body mass index: 27±3 kg/m2) were recruited and randomized to an ES group (n=38) or a placebo control (CON) group (n=39). The ES intervention involved bodyweight exercises whereas CON involved stretching activities performed at lower intensity. Both interventions were conducted at home or work and required minimal space and no specialized equipment. Participants were encouraged to complete a minimum of 9 bouts/wk with a recommended frequency of 3 bouts/d on 3 d/wk. Participants received text and/or email prompts that directed them to a web platform with instructional videos of ES and CON activities that was custom-built by an industry partner. The primary outcome was CRF measured as peak oxygen uptake before and after training. Secondary outcomes included feasibility measured as adherence. This was determined

as the number of bouts recorded as complete in real-time on the web platform and the number of bouts subsequently reported through weekly adherence surveys.

RESULTS: Seventy participants completed the intervention (ES: n=33, placebo: n=37). There was no difference in the change in absolute [0.03 (-0.05 to 0.12) L/min] or relative [0.4 (-0.6 to 1.4) ml/kg/min] CRF after training between ES and CON (constrained baseline linear mixed model, mean difference with 95% confidence interval, both P = 0.43). Total bouts recorded as complete on the web platform over the 12-wk intervention were 171±70 for ES and 152±84 for CON. The number of weekly bouts reported on the adherence surveys were 15±5 for ES and 15±7 for CON. Both reported measures of adherence exceeded the minimum recommendation, which was 9 weekly bouts or 108 total bouts for the entire intervention.

CONCLUSION: A 12-wk technology-enabled, remotely delivered ES intervention was feasible for inactive adults to complete in a real-world setting. The lack of change in CRF may be owing to an insufficient bout intensity under free-living conditions and/or total volume of activity.

Supported by a Canadian Cancer Society/CIHR Action Grant.

EXPLORATION OF ACTIVITIES PEOPLE PARTICIPATE IN TO MEET THE MUSCLE STRENGTHENING PHYSICAL ACTIVITY GUIDELINES

ROSAINI, N.D., GRAY, S., RYDE, G.

UNIVERSITY OF GLASGOW

Introduction

Muscle strengthening activities confer broad health benefits, yet participation remains low. The UK 2019 Physical Activity Guidelines state that people should perform muscle strengthening activities, such as carrying heavy bags, gardening, stair climbing, yoga and going to the gym, at least 2 days per week. It is currently unclear what activities different people do to meet these guidelines. The aim of the current study, therefore, is to identify the activities that people engaged in to meet the guidelines.

Methods

Adults aged 18 to 64 years old living in the United Kingdom were invited to this cross-sectional study through online advertising and asked to complete a survey covering adherence to the guidelines and participation in nine different types of muscle strengthening activities based on a validated questionnaire. Crosstabulation and Pearson Chi-Square test were used to examine the distribution of the types of muscle strengthening activities, separately in males and females.

Results

Of the 620 adults who completed the survey, 77% self-reported that they meet the muscle strengthening guidelines, with higher participation in males (81%) than females (75%). On further analysis, 96% of adults who self-reported not meeting the guidelines did meet the guidelines primarily based on participation in activities such as carrying heavy bags (89% males; 80% females) and stair climbing (93% males; 89% females). In adults who self-reported meeting the guidelines, stair climbing (92% males; 95% females) and carrying heavy bags (89% males; 90% females) were the most frequently reported activities. There were some notable sex differences with males participating more in weight machines (57% males, 40% females, p=0.002) and resistance exercises (80% males, 70% females, p=0.033), but females participating in more holistic exercise (33% males, 55% females, p<.001), such as Pilates and yoga.

Discussion

The data demonstrates that many people who reported not meeting the current muscle strengthening physical activity recommendations do meet it when activities such as stair climbing, carrying heavy bags, and other daily living activities are included. This suggests that these activities need to be specified when ascertaining whether people meet the guidelines. However, whether these activities are sufficient to increase muscle strength and confer the associated health benefits remains to be established. The data also revealed clear differences between men and women in the kinds of activities they perform to meet the guidelines. This information may be important in directing the development of interventions to increase participation in muscle strengthening activities.

DEVELOPMENT AND RELIABILITY TESTING OF THE PERCEIVED ENVIRONMENT AND MUSCLE STRENGTHENING EXERCISE QUESTIONNAIRE

BROWN, E., ZEIGLER-HILL, V., RAJAEE, M., DRIGNEI, D., REZNAR, M., REGENSTEINER, J., DESANDRE, M., GADA, S., BISTAYI, A., SELOU, A., BARKHO, H., PALMER, T.

OAKLAND UNIVERSITY

INTRODUCTION

There are many health benefits to muscle-strengthening exercise (MSE), yet only 23.5% of U.S. adults meet the national MSE guidelines [1]. While barriers to MSE exist, there is a lack of understanding of these barriers [2]. Increasing knowledge in this area may help to encourage its use. Thus, the aim of this study was to develop and test the reliability of a questionnaire that measures how the perceived environment may influence MSE behaviors.

METHODS

The Perceived Environment and Muscle Strengthening Exercise Questionnaire (PEMSE-Q) was developed to understand how MSE may be affected by the environment. Key domains were identified through a literature search, and question-

naire items were developed. Expert review and cognitive interviews were employed to ensure the PEMSE-Q had good content validity and was understood by the target population, respectively. The PEMSE-Q included 77 items measuring the following domains: physical environment, home MSE equipment accessibility, and MSE social support. Test-retest reliability measurements were conducted in a U.S. national sample of two combined independent groups (group 1: healthy adults, n=237 [female(f), n=125; male(m), n=111; intersex, n=1], mean age [±standard deviation, SD]=36.1±10.7 years; group 2: type 2 diabetes [T2D], n=221 [f, n=122; m, n=99], mean age=46.5±10.9 years). Prolific.co is an online research participant recruitment tool, and was used for this study. The factor structure, internal consistency, and test-retest reliability of the PEMSE-Q were calculated using exploratory factor analyses, Cronbach's alpha, and intraclass correlation coefficients (ICCs), respectively.

RESULTS

Exploratory factor analyses revealed the following scales for the PEMSE-Q: physical environment (19 items; e.g., "Muscle-strengthening exercise machine [examples: Bowflex Home Gym®, Total Gym®, or other type of home gym] in your home, yard, or apartment complex." [α=0.77]), accessibility (14 items; e.g., "Muscle-strengthening exercise machine [examples: Bowflex Home Gym®, Total Gym®, or other type of home gym] accessibility." [α=0.79]), and social support (22 items; e.g., "I have someone who can provide support or encouragement in muscle-strengthening exercise." [α=0.90]). For test-retest reliability, the ICCs calculated were 0.94 for the physical environment, 0.83 for accessibility, and 0.88 for social support.

DISCUSSION

The results of the factor analyses showed that physical environment, accessibility, and social support were all separate constructs. Additionally, all of the ICCs suggested that the PEMSE-Q had very good test-retest reliability. The PEMSE-Q is a reliable tool for assessing MSE home equipment and accessibility, convenient MSE facilities, and social support. This tool can be used by researchers, public health professionals, and clinicians to better understand MSE barriers and facilitators in their target population.

VALIDATION OF AN IN SITU ACCELEROMETRY-BASED METHOD TO EVALUATE THE ANAEROBIC THRESHOLD VELOCITY.

ROZIER, P., MOREL, B.

UNIVERSITÉ SAVOIE MONT BLANC

INTRODUCTION: Critical power is an important fatigue threshold in exercise physiology [1]. It delimits efforts in the severe domain, where acute fatigue quickly and drastically appears, from efforts where disturbances remain moderate and can be maintained over long periods. It has great potential applications like evaluating and proposing training programs to improve quality of life of individuals with chronic diseases. However, gold-standard methods that evaluate critical intensity require maximal intensity and/or exhaustion tests, which are extremely difficult to use in a clinical context. In situ methods have been proposed to determine the critical intensity in cycling and running [2]. Training and racing data are compiled over months so the speed-duration relationship can be modelled. Dynamic Body Acceleration (DBA) is an indicator derived from ecological sciences that uses body acceleration as a proxy for locomotion speed [3]. Therefore, this study aimed to assess the validity of critical DBA (DBAc) derived from field data as a reliable proxy for anaerobic threshold velocity.

METHODS: Twelve participants with various physical training and disease conditions wore a 3D accelerometer (GT3X-BT, ActiGraph) for one month. The only instruction was to "continue living as usual". They then performed a submaximal incremental walk test on a 15% inclined treadmill. Blood lactate concentration [La-] was measured at the end of each 3-min stage. The stage speed increment was 0.5 km.h-1 when [La-] < 2 mmol.L-1, and 0.2 km.h-1 when [La-] > 2 mmol.L-1. Exercise was stopped as soon as [La-] > 4 mmol.L-1. An exponential model was fitted to the lactate concentrations as a function of speed to estimate the speed at 4 mmol.L-1 (S4mmol). The mean DBA records for each day were computed for durations ranging from 1 to 30 min. These records were fitted with a 2-parameter critical intensity model using quantile regression ($\tau = 0.9$) to obtain DBAc. The relationship between DBAc and S4mmol was calculated by linear regression analysis (least squares method).

RESULTS: The median values of DBAc and S4mmol were respectively 1.14 m.s-2 (range = [0.43 ; 1.40]) and 5.7 km.h-1 (range = [3.3 ; 6.6]). A very strong correlation was found between DBAc and S4mmol ($r2 = 0.91$, RMSE = 7%, $p < 0.001$).

CONCLUSION: The DBAc obtained from the accelerometry data is a valid proxy for S4mmol. It is therefore possible to characterise the anaerobic threshold of individuals solely on the basis of accelerometry data obtained without any particular instructions during real life. This opens up interesting perspectives for evaluating patients without the need for time-consuming and physically demanding tests. Clinical studies including patient follow-up via actimetry are common and can use the proposed methodology to evaluate patients without additional constraints.

EFFECTIVENESS OF 'BRAIN-IT' - AN EXERGAME-BASED TRAINING CONCEPT FOR SECONDARY PREVENTION OF MILD NEUROCOGNITIVE DISORDER - RESULTS OF A RANDOMIZED CONTROLLED TRIAL

MANSER, P., DE BRUIN, E.D.

ETH ZURICH

INTRODUCTION: The combination of exergame-based motor-cognitive training with resonance breathing guided by heart rate variability biofeedback (HRV-BF) targets various relevant mechanisms of action to alleviate the pathological state in individuals with mild neurocognitive disorder (mNCD).

METHODS: This randomized controlled trial (RCT) investigated the effectiveness of adding a novel intervention approach that combines exergame-based motor-cognitive training with HRV-BF to usual care, compared to usual care alone, in individuals with mNCD. The individualized intervention was delivered via the 'Brain-IT' training concept that was iteratively co-designed, tested, and refined with patient and public involvement [1]. We assessed global (primary outcome) and domain-specific cognitive performance, spatiotemporal parameters of gait, instrumental activities of daily living, psychosocial factors, and resting cardiac vagal modulation. In addition, we evaluated brain structure and function with (functional) magnetic resonance imaging to explore possible underlying neural changes of the training in relation to adaptations in cognitive performance. Analyses of covariance were computed and partial eta-squared (η2p) effect sizes with 90% confidence intervals (CI90%) were calculated.

RESULTS: We observed a significant (p = 0.007) effect with a large effect size (η2p [CI90%] = 0.197 [0.034, 0.371]) for global cognitive performance in favor of the intervention group. A post-hoc power analysis revealed a statistical power of 0.832 for this analysis. 55% of participants in the intervention group and 23% of participants in the control group were responders, showing a clinically relevant improvement in global cognitive performance. For our secondary outcomes, we observed significant effects with large effect sizes in favor of the intervention group for immediate (p = 0.022, η2p [CI90%] = 0.154 [0.013, 0.332]) and delayed (p = 0.007, η2p [CI90%] = 0.204 [0.034, 0.382]) verbal recall, and a borderline significant effect with a moderate effects size for an improvement of quality of life (p = 0.065, η2p [CI90%] = 0.097 [0, 0.263]). The remaining (underpowered) statistical analyses revealed no consistent effects on behavioral outcomes.

CONCLUSION: 'Brain-IT' training is effective for improving global cognitive performance as well as immediate and delayed verbal recall. Confirmatory RCTs are warranted to (i) be able to conclude about potential near- and far-transfer effects of the training, (ii) investigate whether the observed improvements in cognitive performance translate to influencing the progression rates to dementia, and (iii) elucidate the underlying biological mechanisms of action of this novel type of intervention.

VALIDATION OF A NEW DIGITAL HEALTH SOLUTION FOR REMOTE MONITORING OF DAILY LIFE PHYSICAL ACTIVITIES

SCHURMANS, G., BACKES, A., FAYAD, J., MEYER, T., ECKELT, M., GRIMM, B., MOUTON, C., SEIL, R., MALISOUX, L.

LUXEMBOURG INSTITUTE OF HEALTH

INTRODUCTION: A new digital health solution consisting of pressure-sensitive insoles combined with inertial measurement units has been developed to provide clinicians with relevant information on the progress of their patients in their natural environment by detailing aspects of movement quality and quantity, and to monitor their patient's everyday activities. This study aims to test the system's ability to properly identify and quantify different types of daily life activities.

METHODS: Healthy volunteers were invited to complete a series of 12 different usual daily life activities (i.e., sitting straight and relaxed, standing, shuffling, walking straight and non-straight, walking with crutches, hill climbing and descending, stairs climbing and descending, and indoor cycling). Participants were instructed to perform each of the activities twice, in the order and duration of their choice. Data from the system was compared with direct observation of video recording using software for behavioural research. Two observers analysed independently each video recording. Outcomes include both the total duration of each activity and the total counts of events, when appropriate (e.g., steps). The interrater reliability was assessed using Cohen's Kappa statistic (K). The system's accuracy to properly identify and quantify activities was examined by calculating the mean absolute percentage error (MAPE scores) and Bland Altman plots.

RESULTS: A total of 100 participants were included (50 females (50%); median age = 29 years [IQR: 26; 43.3]; median body mass index = 24.7 kg.m^-2 [21.3; 25.9]). The total measurement time was approximately 10 min per participant (activities lasted from 5 to 60 seconds). The interrater reliability was excellent (K=0.85). Overall, MAPE scores between video analysis and the device ranged from 10.4% (total duration of level walking) to 381.1% (total standing count). The system seems to have a general good estimation for some walking duration variables (walking straight, level and non-level walking; MAPE score between 10-20%) and reasonable estimation for the total sitting duration and certain counts (total steps and stairs; MAPE score 20-50%). The performance to identify and quantify the other activities was lower (MAPE score > 50%), and it

seems that the algorithm was particularly ineffective in identifying and quantifying standing count and duration (MAPE score > 100%).

CONCLUSION: In a controlled laboratory environment, the system's performance in classifying and quantifying accurately daily life activities was heterogeneous as some activities were estimated with good accuracy (e.g., walking straight duration) while other activities were erroneous (e.g., standing duration). Further development is needed to improve classification algorithms. Future studies will evaluate the acceptance and ease of use of the system in orthopaedic patients.

THE EFFECT OF SCAPULAR STABILIZATION EXERCISES ON SHOULDER SYMPTOMS AND SCAPULAR POSITION IN PATIENTS WITH SUBACROMIAL IMPINGEMENT SYNDROME

XI, R.1, ZHOU, J.B.2, LI, G.P.2

1 CHINA INSTITUTE OF SPORT SCIENCE; 2 CHINA NATIONAL INSTITUTE OF SPORTS MEDICINE.

INTRODUCTION: Scapular focused exercise interventions are frequently used to treat individuals with shoulder pain. However, evidence for changes in scapular position after intervention is limited. The purpose of this study is to explore the effect of 8-week scapular stabilization exercises on shoulder joint function and scapular position in patients with subacromial impingement syndrome.

METHODS: Methods : 45 patients with subacromial impingement syndrome were randomly divided into intervention group (n = 22) and control group (n = 23). The intervention group received scapular stabilization exercises and two health education courses for 8 weeks (three times a week), while the control group received two health education courses. All outcomes were measured preintervention and postintervention at 8 weeks. Outcome measures were Visual Analogue Score(VAS),Shoulder Pain and Disability Index(SPADI), Coracoid upward shift distance (CUSD), length of the scapular spine line (LSS), and scapular upward rotation angle (SURA) which were measured on the radiographs.

RESULTS: The intervention group showed significant improvement ($p< 0.05$) in VAS and SPADI compared to the control group. Significant changes were found in SURA and CUSD in the intervention group after 8weeks($p< 0.05$).

CONCLUSION: This study indicated that scapular stabilization exercise can improve symptoms and alter the position of the scapula in subacromial impingement syndrome patients.The results provide biomechanical support for the clinical rationale for indicating therapeutic exercises focused on the scapular muscles to improve scapular dynamics and shoulder function.

EFFECTS OF VIDEOCONFERENCE-SUPERVISED GROUP EXERCISE ON LOW BACK PAIN: SHORT AND LONG-TERM RESULTS FROM THE REVIEEW RANDOMISED CONTROLLED TRIAL

ESPIN, A., IRAZUSTA, J.1, RUIZ-FERNÁNDEZ, A.1, MARTÍN-PÉREZ, A.1, ACEDO, K.2, RODRIGUEZ-LARRAD, A.1

1. UNIVERSITY OF THE BASQUE COUNTRY , 2. HOME CARE LAB, S. COOP.

INTRODUCTION: Although benefits of exercise on low back pain (LBP) have been demonstrated, most evidence is limited to short-term effects, and videoconference-supervised interventions are lacking. Therefore, our primary aim was to assess the effects of videoconference-supervised exercise on the LBP of eldercare workers, a population with high prevalence of this disorder. We also included additional pain sites, psycho-affective parameters, muscle performance and sick leave as secondary outcomes.

METHODS: 130 eldercare workers were randomised to a control (CG, n=65) or experimental (EG, n=65) group. Both groups participated in workplace prevention programs, and the EG received an additional 12-week exercise intervention, consisting of progressive moderate-intensity resistance exercises. The intervention was followed by advice to continue exercising until a 48-week follow-up. Assessments were done at baseline, 12 and 48 weeks. Primary outcome was LBP, measured by a 0-10 scale. Secondary outcomes included: neck, shoulder and hand/wrist pain (0-10 scale), pain medication (days), happiness (Lyubomirsky's scale), anxiety and depression (Goldberg's scale), quality of life (EuroQol-5D), sleep quality (single-item scale), hypnotic/anxiolytic medication (days), lower-limb (5-repetition sit-to-stand), upper-limb (kneeling push-up) and trunk (Shirado-Ito flexor) muscle performance, and sick leave (days). Group-by-time ANCOVA was used to assess intervention effects, and both intention-to-treat (ITT) and per-protocol (PP, adherence ≥50%) analyses were done. Significance was set at $p<0.05$.

RESULTS: At 12 weeks, ITT showed a beneficial effect on LBP ($p=0.034$), as well as on hand/wrist pain ($p=0.023$) and upper-limb muscle performance ($p=0.040$). PP demonstrated additional benefits in depression ($p=0.021$), quality of life ($p=0.002$), hypnotic/anxiolytic medication ($p=0.011$) and lower-limb ($p=0.026$) and trunk ($p=0.030$) muscle performance. At 48 weeks, ITT showed a loss of the beneficial effect on LBP, as well as on hand/wrist pain and upper-limb muscle performance. However, a reduction in hypnotic/anxiolytic medication was observed ($p=0.006$). Moreover, PP demonstrated additional benefits on depression ($p=0.033$), trunk muscle performance ($p=0.049$) and sick leave ($p=0.013$).

CONCLUSION: The intervention reduced the LBP of eldercare workers at short-term. However, despite the advice to continue exercising, this improvement was not maintained at long-term. Additional benefits were observed in hand/wrist pain and upper limb muscle performance at short-term, as well as in hypnotic/anxiolytic medication use at long-term. Moreover, workers with higher adherence to the intervention had additional benefits in psycho-affective parameters and sick leave. This study provides new evidence on an alternative, feasible and effective exercise modality to reduce LBP in eldercare workers. However, advice to continue exercising was not able to maintain most of the benefits obtained.

EFFECTS OF ACTIVE-MOTOR-CONTROL MYOFASCIAL RELEASE ON CHRONIC SHOULDER PAIN IN OVERHEAD ATHLETES

HUANG, T., ZOU, H.L., ZHANG, W., LIU, H.Y., YAN, B.
BEIJING SPORT UNIVERSITY

INTRODUCTION: Chronic shoulder pain (CSP) affects 50%–91% of overhead athletes, severely impacting their training and competition [1]. Although scapular stabilization exercise (SSE) is a first-line treatment, it has a limited and slow effect on pain relief [2]. This study introduces an integrated approach combining active motor control with myofascial release (AMC-MR), aiming to enhance pain relief and functional recovery in overhead athletes with CSP [3].

METHODS: Twenty-four overhead athletes with CSP were randomized into AMC-MR and SSE groups for a 6-week intervention. The AMC-MR group received treatment weekly, while the SSE group had sessions three times weekly. Primary outcomes were pain intensity assessed by the Numeric Rating Scale (NRS, 0-10 scale), including present, average, and most severe pain intensity. Secondary outcomes included Kerlan-Jobe Orthopaedic Clinic Shoulder and Elbow Score (KJOC) for patient-reported outcomes, active range of motion (AROM), and maximum isometric muscle strength (MIMS). Average and most severe pain intensity and KJOC were assessed at baseline and 6 weeks. Present pain intensity, AROM, and MIMS were assessed at baseline, after the first session, and at 6 weeks.

RESULTS: All participants completed the study without dropouts. For primary outcomes, present pain intensity was 4.00±1.21 in the AMC-MR group and 4.16±1.53 in the SSE group at baseline. The AMC-MR group showed a significant reduction in present pain intensity after the first session (1.08±1.38) and at 6 weeks (0.75±0.97), surpassing the SSE group significantly after the first session (P=0.02), with the SSE group also noting significant present pain relief at 6 weeks (1.83±1.89). Both groups showed considerable improvements in average and most severe pain intensity at 6 weeks. Secondary outcomes revealed significant improvements in both groups for KJOC, and shoulder abduction and flexion at 6 weeks, with the AMC-MR group showing superior improvement in KJOC (P=0.02). The AMC-MR group also notably enhanced AROM including external rotation, internal rotation, abduction, and flexion after the first session, with external rotation improvements outperforming the SSE group (P=0.01). No significant changes were observed in MIMS for the serratus anterior and trapezius in either group.

CONCLUSION: AMC-MR has shown clear advantages in both rapid pain relief and improved function, as well as duration of efficacy.

EVALUATING PHYSICAL THERAPIES FOR DELAYED ONSET MUSCLE SORENESS: AN EVIDENCE MAPPING

WIECHA, S., POSADZKI, P., ZAJAC, J., WISNIOWSKI, P., PAWLICZEK, P., CIESLINSKI, M., PRILL, R., CIESLINSKI, I., PLASZEWSKI, M.
JOZEF PILSUDSKI UNIVERSITY OF PHYSICAL EDUCATION, WARSAW, POLAND.

INTRODUCTION: Delayed onset muscle soreness (DOMS) commonly arises from intense and unfamiliar physical exertion, leading to diminished muscular strength, heightened soreness, and inflammation. Various systematic reviews (SRs) evaluate diverse physical therapy (PT) approaches aimed at reducing DOMS. Nevertheless, these SRs frequently yield conflicting findings, hindering the formulation of therapeutic strategies by clinicians.

METHODS: An umbrella review method with meta-meta-analysis has been utilized to evaluate the efficacy and safety of PTs in reducing DOMS. Medline, Embase, Cochrane Database of Systematic Reviews, PEDro, and Epistemonikos were searched from 1998 until May 2023. SRs of RCTs of any treatment used by physical therapists or physiotherapists to reduce DOMS in healthy adults have been eligible. AMSTAR-2 has been used to evaluate the risk of bias of the included SRs. An evidence map categorized interventions based on the effect size and strength of evidence (Class I-V based on the number of cases, p-value, heterogeneity, Egger's test, and excess of significance bias).

RESULTS: Twenty-nine SRs (24 with meta-analysis) meet inclusion criteria, including 863 unique RCTs. Interventions were diverse, including 24 different PTs. The quality of SRs was generally low, with only 7% rated as high quality.

With the highest strength of evidence, significant effects in pain reduction were observed immediately after post-exercise intervention in contrast therapy (Class II), massage therapy at 24 hours (Class II), compression, contrast therapy, Kinesio taping, and cryotherapy at 48 hours (Class III), Kinesio taping at 72 hours (Class III), while compression, phototherapy, and

contrast therapy showed effectiveness at 96 hours (Class IV). The effect size (Hedges' g) varied widely for individual therapies from 0.36 [95%CI 0.46, 3.18] for cold therapy to 1.82 [95%CI 0.46, 3.18] for heat therapy, with a prominent increase in the 95%CI as the effect size increased.

CONCLUSION: This is the first umbrella review to analyze the effects of different therapeutic interventions on pain reduction in DOMS. In the analyzed SRs, therapies were not directly compared with each other or ranked by the strength of scientific evidence. The overlap between SRs varied, indicating differences in search strategies. The analyses reveal a wide disparity in the effectiveness of PTs and an overall low strength of scientific evidence for most therapies. This may be attributed to the high methodological heterogeneity of first-line studies and the significant internal variation in the therapies applied.

EFFECTS OF MICROCURRENT THERAPY ADDED TO PHYSICAL EXERCISE ON BODY COMPOSITION, PERFORMANCE, AND MUSCLE SORENESS: A META-ANALYSIS OF RANDOMISED CONTROLLED TRIALS

KOLIMECHKOV, S., SEIJO, M., COLADO, J.C., NACLERIO, F.

UNIVERSITY OF GREENWICH

INTRODUCTION: Microcurrent therapy (MCT) uses sub-sensory electric current across the skin to enhance healing after injury, improve post-exercise recovery or optimise training outcomes in athletes. This meta-analysis aimed to assess the effectiveness MCT combined with physical exercise for attenuating symptoms of delayed onset muscle soreness and enhancing body composition, muscle strength, and endurance compared to exercise alone (sham MCT with exercise) in physically active individuals.

METHODS: A meta-analysis was performed according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). The search of the literature was conducted using Cochrane Library, EBSCOhost, Google Scholar, MEDLINE PubMed, and Web of Science, considering publications until the 1st of February 2024. The inclusion criteria were randomised controlled trials (RCTs), including adult participants (≥18 years old) undergoing any exercise intervention combined with MCT or a sham (control condition). Continuous data on fat mass percentage, maximum load moved in resistance exercises (1RM) as a marker of strength, VO2peak as a marker of endurance, and delayed onset muscle soreness (DOMS) were pooled using a random-effects model. The Comprehensive Meta-Analysis Software, v. 4.0.000 (Biostat Inc., Englewood, New York, USA) was used for the analysis.

RESULTS: Data from eleven RCTs were included in the qualitative summary and six in the quantitative analyses (n=364 participants). The overall quality of the included studies was high, demonstrating a low risk of bias. Compared to sham, MCT added to exercise significantly reduced the symptoms of DOMS (g = -0.487, 95 % CI -0.75 to -0.23). No further significant benefits of MCT were identified for fat mass percentage (g = -0.144, 95 % CI -0.48 to 0.19) or strength (g = 0.116, 95 % CI -0.45 to 0.69).

CONCLUSION: MCT added post-workout is an effective, safe modality for reducing the symptoms of delayed onset muscle soreness in healthy physically active humans.

EFFORT MANAGEMENT IN SHORT TRAIL RUNNING: QUALITATIVE ANALYSIS BY SELF-CONFRONTATION

DE COCK, F., FOSSION, G., ECCLI, C., PAQUOT, Q., JIDOVSTEFF, B.

UNIVERSITY OF LIÈGE

INTRODUCTION: According to Glazier's model (2017), self-organization plays a key role in short trail running performance. As a consequence, understanding how trail runners' particular possibilities for acting, feeling and thinking which are embedded in the race topography, environment and circumstances would be helpful to understand effort management and performance. A qualitative approach using the self-confrontation method would appear to be the most appropriate way to investigate the main effort management processes used by runners during a trail running.

METHODS: Subjects participating in a short trail race (10 to 30km) were equipped with a GoPro and a Garmin watch in order to record their activity throw GPS data and video recording. In the 5 days following the race, each subject participated in a self-confrontation interview following a thematic analysis. They were asked to describe for each relevant event what they feel, think and the decisions they make according to race chronology. Via a triangulation of researchers, the interviews were transcribed and coded to immerse main management processes.

RESULTS: The qualitative approach used in this study gave rise to a plurality of experiences and was successful to identify and characterize particular ways of acting in a running situation. Based on Glaziers model (2017), effort management and trail running performance depend on the task, the environment and the organism. We found that runners organize themselves according to the constraints that influence their perceptions, feelings, cognitive processing and decision-making which are particularly influenced by the chronology of the race. We identify strategies influencing the management of effort such as trail recognition, position on the start line, goal setting, management of vitality, nutrition and hydration, motivation and pleasure.

CONCLUSION: The results of this qualitative research was successful to identify main effort management strategies during short trail running. The data from this study provide a better understanding of how runners coordinate their control throughout the race, especially in delicate moments, and could be used to optimize performance.

COMPARATIVE ANALYSIS OF EVENT-RELATED POTENTIAL AND VISUAL WORKING MEMORY IN ELITE GYMNASTICS, FOOTBALL, AND ESPORTS ATHLETES

RAMYARANGSI, P., SIRIPORNPANICH, V.1, NANBANCHA, A.1, POKAISASAWAN, A.2, AJJIMAPORN, A.1
MAHIDOL UNIVERSITY NAKHON PATHOM, THAILAND; 2 RANGSIT UNIVERSITY, BANGKOK, THAILAND

Introduction

The significance of the visual system and the specific acquisition of visual skills for enhancing athletic performance is paramount in elite sport (Erickson, 2020). Sports, such as gymnastics, football, and eSports, may necessitate equally unique visual abilities. As such, research has placed an increasing emphasis on better understanding the nuances of visual cognition in athletes across different sports. The purpose of this investigation was to examine and contrast the characteristics of the P300 evoked potential elicited by a visual oddball paradigm (visual P300 ERP) and visual working memory among elite athletes from three distinct sports.

Methods

A total of 42 athletes across three sports participated in the study. Of these, fourteen were gymnasts (age: 20±1 yrs, BMI: 22.0±1.5 kg/m2), fourteen were footballers (age: 21±1 yrs, BMI: 20.8±2.5 kg/m2), and fourteen were eSports athletes (age: 21±2 yrs, BMI: 21.5±3.3 kg/m2). Participants had normal or corrected-to-normal vision and right-hand dominance and undertook the visual P300 ERP using electroencephalography and used the Gorilla.sc experiment builder program to evaluate visual working memory (n1-back and n2-back). Data analysis among the three athlete groups was performed using a one-way ANOVA. The Bonferroni post hoc test was used for pairwise comparisons.

Results

Results revealed notable differences among the athlete types in visual P300 ERP. The eSports group demonstrated a significantly longer P300 latency than the gymnastic group ($p=0.01$) at the midline Frontopolar site of electrodes, but there were no differences in amplitude. In addition, both the eSports ($p=0.03$) and gymnastic ($p=0.04$) groups exhibited a superior percentage of correct responses in visual ERP compared to the football group. Regarding mean visual ERP reaction time, the eSports group exhibited significantly longer durations than both the soccer ($p<0.01$) and gymnastic ($p<0.01$) groups. Moreover, the mean reaction time of the soccer group was significantly longer than the gymnastic group ($p<0.01$). There were no differences among the groups for the visual working memory task.

Discussion and Conclusion

These findings demonstrate that the visual P300 ERP observations in athletes are different contingent on the type of sport. In doing so, it adds further credence to the notion of sport-specific characteristics in visual attention. Future research that takes into consideration how the specific training regimens and cognitive demands of different sports influence visual processing might yield further valuable insights that would add to the knowledge base.

EXPERT PERFORMANCE IN ACTION ANTICIPATION: VISUAL SEARCH BEHAVIOR IN VOLLEYBALL SPIKING DEFENSE FROM DIFFERENT VIEWING PERSPECTIVES

ZHU, R., ZOU, D., WANG, K., CAO, C.
TSINGHUA UNIVERSITY

Introduction

Volleyball spiking requires defenders to possess exceptional anticipatory skills. Athletes' visual search skills, enable them to execute appropriate responses, thereby facilitating effective anticipation. Behavioral studies have consistently demonstrated that athletes tend to exhibit superior perceptual-cognitive abilities, particularly in sports-specific contexts. In addition to subjective methods such as verbal reports, eye-tracking devices can be used as scientifically objective instruments to measure expert athletes' visual search skills. However, Previous volleyball defense video eye-tracking studies used fixed or off-court perspectives, failing to replicate real-world environments. The present study investigated visual search behaviors in spike defense anticipation from different back-row viewing perspectives, including one baseline off-court perspective and three on-court perspectives.

Methods

We examined the spiking anticipation ability and visual search behavior of 14 competitive elite, 13 semi-elite, and 11 novice players using the Tobii Pro eye-tracking device. We let them see the spiking video and instructed them to press a key to anticipate the landing location of the ball. For video production, We captured spiking videos from three on-court perspectives using GoPro cameras mounted on the back-row defenders heads, closely replicating real game scenarios. For comparison, we recorded baseline videos using a fixed camera. For Areas of interest, we divided videos into 2 phases: pre-spike and spiking phase. We used repeated ANOVA and subsequent Bonferroni post hoc analyses in SPSS to explore the differential effects between groups and perspectives.

Results

The repeated measures ANOVA with factors 3 (group) × 4 (perspective) demonstrated a notable interaction effect on RA ($F(6,68) = 2.204$, $p = 0.050$, $\eta 2 = 0.163$). The CE (58.5% ± 3.3%) and SE (56.3% ± 5.0%) groups were significantly superior to the novice group (49.9% ± 4.8%). Competitive elite players used fewer fixations($t=6.241$, $p<0.001$). Regardless of skill level, all participant groups showed similar visual allocation among areas of interest. However, notable differences in visual search patterns and AOI allocation were observed between baseline and on-court perspective videos ($F(3, 35) = 123.108$, $p < 0.001$, $\eta 2 = 0.918$).

Discussion

Elites are more skilled than novices in utilizing early visual cues to anticipate opponents' actions. Elites superior performance was related to stable visual search patterns (fewer fixations and longer duration). CEs are likely more adept than SEs and novices at utilizing their peripheral vision for global perception. From the baseline perspective, the participants primarily utilized global perception and peripheral vision, focusing more on the setter zone or the spiker's trunk. Conversely, from the on-court perspective, they employed more fixations, focusing more intensely on the spiker's detailed movements.

THE COMPLEX RELATIONSHIPS BETWEEN VO2MAX METRICS, COGNITIVE AND BRAIN OUTCOMES IN OLDER ADULTS

BHERER, L., MAGNAN, P.O., VINCENT, T., BESNIER, B., DUPUY, E., GAGNON, G., MOHAMMADI, H., NIGAM, A., GAYDA, M.
UNIVERSITY OF MONTREAL

Background: Exercise-related physiological adaptations by which it improves brain function are still poorly known. Some studies, including ours, have shown that change in VO2max is a strong predictor of cognitive benefits, but the underpinning physiological mechanisms are not well documented. This study investigated which VO2max metrics better predict various cognitive functions and brain imaging structural markers known to be altered in aging.

Methods: Ninety adults aged 60 and older performed a maximal cardiopulmonary exercise Test (CPET) using an individualized incremental bike protocol according to the most recent recommendations. CPET key parameters were measured with gas exchange analyze (Quark, Cosmed, Italy) during exercise test. They also participated in an MRI session to acquire T1 brain images (1x1x1 mm, Siemens Skyra 3T). CPET key parameters were VO2max normalized with body mass, lean body mass and in % of predicted value (VO2max/kg, VO2max/LBM, VO2max % pred. Brain imaging involved hippocampal volume (average of left and right sides), total grey matter and T1 Hypointensities volumes normalized by intracranial volume as obtained by the Freesurfer segmentation pipeline (version 7.4).

Results: All VO2max metrics were associated to some extent with global cognition, executive function, verbal and working memory, and processing speed. However, when considering composite scores of cognitive performances, and after controlling for age, sex and education, VO2max/kg ($p.<.05$) and VO2max/LBM ($p.<.01$) predicted executive functions, while VO2max % pred was the only significant predictor of verbal memory ($p.<.001$), and none of the VO2max metrics predicted processing speed. All brain imaging measures predicted executive functions ($p.<.05$), while only total grey matter ($p.<.001$) and hippocampal volumes ($p.<.05$) predicted verbal memory. VO2max/LBM and VO2max % pred predicted all brain imaging measures ($p.<.05$), while VO2max/kg only predicted T1 Hypointensities ($p.<.001$). Significant partial mediation effects were independently found for total grey matter ($p.<.05$) and hippocampal volumes ($p.<.05$) explaining the association between VO2max/LBM and executive functions.

Conclusion: Results support the notion that VO2max metrics are not equivalent predictors of cognitive functions and brain imaging outcomes, highlighting the importance of consistency in reporting results on the relationship between cardiorespiratory fitness and cognition. These results could also inform on more targeted and personalized exercise intervention to maintain and improve cognition and brain health in seniors.

THE INTERUNIT RELIABILITY OF STATSPORTS APEX GLOBAL NAVIGATION SATELLITE SYSTEM (GNSS) AND ACCELEROMETER METRICS DURING REPEATED SPRINTS OF VARIED DISTANCES AND CHANGE OF DIRECTION FREQUENCY.

DAWSON, L., MCERLAIN-NAYLOR, S., DEVEREUX, G., BEATO, M.
ST MARYS UNIVERSITY TWICKENHAM

INTRODUCTION: The importance of athlete monitoring in team sports is now widely recognised and commonly achieved using GNSS trunk-mounted player tracking systems. Systems allow for the output and interpretation of multiple external load metrics which practitioners use to inform the prescription and adaptation of training load. However, interunit reliability is important to allow comparisons to be made within and between athletes and teams. The aim of this study was to assess the interunit reliability of STATSports Apex units during repeated sprints of varied distances and changes of direction, to assess how reliability and metrics may change with the demands of repeated sprints.

METHODS: Thirty-three female football players performed 5 sets of 2 x 20 m, 4 x 10m and 8 x 5 m repeated sprint protocols (200m total), while wearing two harnesses and STATSports Apex GNSS units, placed alongside each other, between the scapulae. The interunit reliability was assessed using intraclass correlation coefficient (ICC), for each protocol and all combined, for a selection of GNSS and accelerometer-based (ACC) metrics. One-way ANOVAs were used to compare the metrics reported for each sprint protocol.

RESULTS: Across all protocols GNSS metrics demonstrated good to excellent interunit reliability (ICC: 0.845 - 0.999), while ACC metrics fatigue index (ICC: 0.495) and dynamic stress load (ICC: 0.484) were poor. Variation in reliability across individual sprint protocols was found for accelerations (2 x 20m ICC: 0.692, moderate; 4 x 10m ICC: 0.865, good; 8 x 5m ICC: 0.789, good), metabolic distance (2 x 20m ICC: 0.871, good; 4 x 10m ICC: 0.928, excellent; 8 x 5m ICC: 0.974, excellent), fatigue index (2 x 20m ICC: 0.393, poor; 4 x 10m ICC: 0.438, poor; 8 x 5m ICC: 0.544, moderate), and dynamic stress load (2 x 20m ICC: 0.445, poor; 4 x 10m ICC: 0.455, poor; 8 x 5m ICC: 0.539, moderate). Notably, despite increased acceleration and deceleration demands with more changes of direction, ACC metrics were not significantly different between any sprint protocols ($p = 0.064 - 1.000$).

CONCLUSION: GNSS metrics show good to excellent interunit reliability, except for accelerations (moderate to good), therefore it is recommended that practitioners can confidently use APEX GNSS units for load monitoring of GNSS metrics. However, ACC metrics have demonstrated largely poor to moderate interunit reliability and highlighted difficulty distinguishing between the demands of varied sprint distances. It has been recognised that the ICC increases from 2 x 20m to 8 x 5m, suggesting that reliability may improve by increasing the amount of activity monitored. Therefore, short protocol duration may also explain the lack of significant differences identified between sprint protocols. It is recommended to avoid the interchanging of units between athletes and sessions, and interpret ACC metrics cautiously, with regard to the type and duration of activity being monitored.

IMPACT OF TENNIS SPECIFIC HITTING AND RUNNING LOADS ON RESPIRATORY PATTERNS COMPARED TO TREADMILL RUNNING WITH SIMILAR OXYGEN UPTAKE

RAASCH, K., EDEL, A., FERRAUTI, A.
FACULTY OF SPORTS SCIENCE, RUHR UNIVERSITY BOCHUM

INTRODUCTION: Studies on respiratory patterns in tennis are rare and there is no evidence regarding the relation between stroke production, breathing patterns and oxygen uptake. Therefore, the aim of this study was to compare respiratory patterns and gas exchange during a standardized tennis protocol with corresponding measures during continuous treadmill running at a similar oxygen uptake.

METHODS: 15 female and male competitive tennis players (women n= 7: age: 22.6 ± 2.4 years, weight: 69.7 ± 11.9 kg, height: 172.6 ± 8.0 cm; men n= 8: age: 25.5 ± 3.1 years, weight: 83.4 ± 8.2 kg, height: 187.4 ± 6.8 cm) completed three experimental parts on separate occasions. A standardized tennis protocol (TP, Day 1), a treadmill-based incremental running test (RT, Day 2) and a standardized running protocol metabolically matched to TP (RP, Day 3). TP (Day 1) included low or high running loads (RL, RH) and low or high stroke velocities (SL, SH) which were combined in four stages (TP1: RL+SL; TP2: RL+SH; TP3: RH+SL; TP4: RH+SH). RT (Day 2) was used to determine the running velocity matching the oxygen consumption during each stage of TP (TP1-TP4). RP (Day 3) included four stages with identical length and oxygen consumption as during TP. Oxygen uptake (VO2), energy expenditure (EE), tidal volume (VT), breathing frequency (bf), minute ventilation (V'E), inspiration (tI) and expiration time (tE) as well as stroke velocity (SV) were compared between TP and RP. Number (NP) and duration of breathing Plateaus (DP) were calculated from VT. A plateau was defined as a minimum of 0.2 s with no air exchange and constant VT. TP was recorded by video and synchronized to respiratory data. Repeated measures ANOVA was used to compare TP and RP on each stage.

RESULTS: Mean VO2 (p<.001), EE (p<.001), and RER (p<.001) increased significantly between stage 1 to 4 but did not differ between TP and RP. TP corresponded to mean running velocities of 3.2±0.2 m/s (RP1), 3.5±0.4 m/s (RP2), 3.8±0.5 m/s (RP3) and 4.2±0.5 m/s (RP4). Regarding respiration parameters, NP was significantly higher in TP compared to RP on stages TP2 (5.9±3.8vs.0.4±0.5,p<.001), TP3 (2.6±2.7vs.0.3±0.6,p=0.04) and TP4 (4.6±4.1vs.0.3±0.6,p<.001). No significant differences were observed for VT, bf, V'E, tI and tE between TP and RP. Specifically in tennis, VT (1.8±0.4 vs. 2.9±0.7 L/s,p<.001), bf (36.2±7.7vs.44.3±6.6 b.min-1,p<.001) and V'E (52.9±11.3vs.85.0±18.4L/min,p<.001) increased from TP1 to TP4, whereas tI (0.9±0.2vs.0.8±0.1s,p<.001) and tE (0.9±0.2vs.0.7±0.1s,p<.001) decreased. NP was higher in TP2 (p<.001) compared to TP1, whereas no differences were found between TP3 and TP4 and DP.

CONCLUSION: Respiration patterns differ significantly between tennis and running. Breathing plateaus occur exclusively in tennis during a time window around the hitting point and can be attributed to a higher hitting power. These specific demands might come along with challenges for coaches since powerful strokes can be accompanied with individual respiratory disturbances.

DIFFERENCES IN PRE- AND POSTSEASON PERFORMANCE INDICES OF SWEDISH ADOLESCENT FLOORBALL PLAYERS.

UHRAS, B., TERVO, T., THEOS, A.

SECTION OF SPORTS MEDICINE

INTRODUCTION: Previous research conducted in floorball has focused on sports related injuries and on its health benefits for older adults [1, 2]. Monitoring players' performance capabilities throughout the season has been previously examined in football players [3, 4], but no previous study has examined how competition season affects floorball players' physical performance.

The purpose of the present study was to examine differences in pre- and postseason performance indices of Swedish adolescent floorball players.

METHODS: A total of 420 adolescent floorball players, 232 boys (age:18.9 ± 0.8 years) and 188 girls (age:18.9 ± 0.8 years) participated in the study. Performance testing included pushups (upper body strength), one-leg sit to stand test (lower limb unilateral strength), broad jump (lower body power and explosiveness), 20m shuttle run test (aerobic endurance) and hexagonal obstacle (agility and coordination). The tests were conducted before (PRE) and directly after (POST) the 2022-23 floorball season. Differences in performance indices were analyzed with the use of paired t-test. The level of significance was set to α=0.05. Data are presented as mean ± standard deviation.

RESULTS: Performance in pushups (PRE: 20.0 ± 12.8 vs. POST: 20.9 ± 13.2 reps, p=0.03), one-leg sit to stand test left leg (PRE: 5.0 ± 1.4 sec vs. POST: 4.7 ± 1.1 sec, p<0.001) and right leg (PRE: 5.0 ± 1,3 sec vs. POST: 4.6 ± 1.1 sec, p<0.001) and hexagonal obstacle clockwise (PRE: 10.9 ± 1,6 sec vs. POST: 10.5 ± 1.3 sec, p<0.001) and anti-clockwise (PRE: 11.0 ± 1.5 sec vs. POST: 10.6 ± 1.4 sec, p<0.001) differed significantly between pre- and post-season. No statistically significant differences were observed in standing broad jump (PRE: 215 ± 27.3 cm vs. POST: 216 ± 30.2 cm, p=0.104) and 20m shuttle run test (PRE: 53.2 ± 7.13 ml/kg/min vs. POST: 52.8 ± 7.23 ml/kg/min, p=0.150).

CONCLUSION: The findings suggest that in-season floorball training has positive effects in strength and agility performance indices but no significant effects in explosive strength and aerobic fitness, despite floorball's high-intensity intermittent work character.

RELATIONSHIP BETWEEN CURVE SPRINT, LINEAR SPRINT, VERTICAL JUMP, AND CHANGE OF DIRECTION ACROSS DIFFERENT AGE CATEGORIES IN SOCCER PLAYERS.

BARROS, T., NAKAMURA, F.Y., FILHO, R.S.L., SILVA, N.M.G., LIMA, V.F., BIBROWICZ, B., HENRIQUE, R.S.

UNIVERSIDADE FEDERAL DE PERNAMBUCO

INTRODUCTION: Sprinting in soccer has received considerable attention due to its occurrence at decisive moments of the match (1). However, most sprint actions occur in a curvilinear trajectory (2). Few studies have investigated which field-based physical abilities correlate with curved sprinting (CS) performance, and how these relationships evolve across age categories. Thus, the the study aimed to investigate the differences of CS from the U-13 to Senior category and the relationship between CS and different physical abilities (linear sprint, change of direction, and vertical jump) in highly trained soccer players across different age categories.

METHODS: 121 male soccer players from the U13 (n=25; 11.0-12.9 years old), U15 (n=35; 13.0-14.9 years old), U17 (n=31; 15.0–16.9 years old) and Senior (n=30; aged 25.59 ± 3.83) categories of a Brazilian soccer club performed: (1) maximal 20-m linear sprint (LS) test (2) maximal 17-m CS test on arc of the area of an official soccer field with dominant and non-

dominant legs; (3) Zigzag 20 m change-of-direction (COD) test; and (4) a countermovement jump (CMJ) test on a contact platform. The CS test was then classified as a good side (fastest side) and a weak side (slowest side). Pearson's correlation test and One-way ANOVA were used to verify the relationship between physical tests and to compare performance tests according to the maturity groups, respectively. Cohen's d effect size was used to the magnitude of differences between groups in the CS performance.

RESULTS: CS performance for the good and weak sides increased as age categories increased, Differences between all pairs of age categories were moderate to very large, with Cohen's d varying from 0.90 to 5.72 for both legs. Correlations were found for CS good and weak side, and LS-20m in all groups, with r-values varying from 0.38 to 0.77. Only the U-15 and U-17 groups exhibited statistically significant correlations between CS and COD, for both age categories the r-values were lower in the CSGS (r = 0.46 and 0.48) than CSWS (r = 0.59 and 0.64). Excepting for the U-17 group, correlations between CS and CMJ were statistically significant in all age categories for both the good and weak sides (U-13: r = 0.61 and 0.67; U-15: r = 0.46 and r = 0.66; Senior: r = 0.57 and r = 0.58).

CONCLUSION: CS performance evolved across age categories. In addition, moderate to moderately high relationships were observed between CS, both on the good and weak sides, and LS, 20-m COD, and CMJ performance, although the pattern did not always increase or decrease as a function of advancing age. Given that the most strongly correlated tests only shared a maximum of 46% of the shared variance, it is plausible to assume that in soccer players under the age of 17, maximum sprint speed in curved and linear trajectories, COD, and CMJ are abilities that can be considered and trained independent of each other.

BOTH VERTICAL AND HORIZONTAL PLYOMETRIC TRAINING INFLUENCE SPRINT FORCE-VELOCITY PROFILE IN YOUNG ELITE SOCCER PLAYERS.

FOURÉ, A., NORGEOT, F.
UNIVERSITÉ CLAUDE BERNARD LYON 1

INTRODUCTION: During a soccer match, sprint horizontal acceleration ability is determinant for performance. Development of sprint force and velocity qualities has been reported after plyometric training (1). However, the orientation of plyometric training exercises can influence functional performance (2). The purpose of this study was to compare horizontal and vertical orientation plyometric training on explosiveness performance and sprint force-velocity profile in young soccer players.

METHODS: Twenty-eight soccer players were recruited and divided in two groups: vertical group (VG, n = 14) and horizontal group (HG, n = 14). Tests including vertical and horizontal jumps (i.e., squat jump [SJ], countermovement jump and 30-cm drop jump [DJ]) and a 30-m sprint were conducted before and after the 8-wk training period. Sprint force-velocity profile (FVP) was evaluated during a 30-m sprint test.

RESULTS: The results demonstrated significant improvements in both VG and HG for vertical jump performances (from +5.0% to +11.5%), horizontal jump performances (from +5.6% to +9.8%), sprint times (from -4.7% to -12.2%) and FVP parameters. Higher decrease in sprint performance for HG were found in 5-m (VG: -6.4% vs. HG: -12.2%) and 15-m (VG: -4.7% vs. HG: -8.6%) sprint times, horizontal DJ (VG: +5.8% vs. HG: +9.8%), but also in FVP parameters, especially the maximal power (VG: +16.4% vs. HG: +28.1%) and the horizontal orientation of force (VG: no significant difference vs. HG: +22.9%) during the 30-m sprint ($P < 0.05$).

CONCLUSION: Both horizontal and vertical plyometric training can be either used in young soccer players to improve vertical and horizontal performances in jump and sprint as previously reported (3). However, horizontal plyometric training may give a larger gain in horizontal ballistic actions while developing vertical jump qualities in young soccer players. Further studies are necessary to more deeply compare motor coordination and muscular synergies involved in vertical and horizontal actions and potential specific effects on musculoskeletal structural adaptations.

WELL-BEING AND EXERTION INDICATORS OF AN ELITE GERMAN FIELD HOCKEY TEAM: A COMPARISON OF A COVID IMPACTED SEASON AND REGULAR SEASON

RAHLF, L., KHER, S.1, MÖLLER, L.2, FÖRSTER, M.1, MASON, J.3, ZECH, A.3
1 EUROPA-UNIVERSITÄT FLENSBURG, 2 UNIVERSITÄT HAMBURG, 3 FRIEDRICH-SCHILLER UNIVERSITY JENA

INTRODUCTION: The German domestic hockey league was interrupted by the COVID pandemic just like all sports leagues around the world, which resulted in a higher density of match play upon return. Evidence indicates that a higher density of match play in hockey increases the risk of injury (Mason et al., 2021), but little is known about internal and external load (and their interactions) during the period of restricted public life compared to a regular season.

METHODS: During the second half of the outdoor seasons 2021 and 2022, 33 players of a national division one field hockey team were asked daily about their internal load via well-being surveys on sleep quality, fatigue, soreness, stress, mood, and post-session perceived exertion (RPE). The well-being items were summed to create an averaged readiness

score. Additionally, the training and match load (carried over exposure; CoE) were tracked to assess external load. The individual values of the players were aggregated for each day of the season. A linear regression analysis was performed and the variables of well-being and RPE were controlled for season, day of the season and exposure.

RESULTS: Overall, the analysed data included n= 66 seasonal days (32 and 34 days in season 2021 and 2022 respectively). None of the well-being indicators, including overall readiness score, differed significantly between seasons. However, all indicators of well-being showed lesser values on later days in both seasons as well as the greater the exposure the stronger the state of fatigue and soreness. Considering the power and the beta error, tendencies towards higher RPE values over the season were observed as well as tendencies towards lower sleep quality and stress with increasing exposure.

CONCLUSION: The results show that the season progress and exposure is affecting well-being and exertion. The athletes showed lesser well-being on later days in the season and higher tendencies of exertion. In terms of exposure, the athletes showed higher soreness, fatigue and a trend to reduced quality of sleep and stress levels. Although no specific seasonal effect was found, the results show that higher exposure leads to reduced well-being and greater exertion, which may indicate inadequate management of higher exposure and may lead to further consequences such as injury or symptoms of overtraining.

ANALYSIS OF EYE GAZE DURING OFFENSE SITUATION WITHOUT BALL HOLDING IN BASKETBALL : COMPARISON OF SKILLED AND UNSKILLED PLAYERS

SAITO, T., NAKAJIMA, T.

北海道教育大学大学院

INTRODUCTION: Vickers (1996) found that players with a free throw success rate of 75% or more are characterized by a long gaze on one point in the ring just before the start of the ball down, while players with a free throw success rate of 60% or less have an unstable gaze in the ring or backboard. Kato (2002) reported that skilled people are relatively looking at the center of the field of view, but unskilled people tend to vary greatly from enforcement to enforcement. In addition, the gaze behavior of skilled people when jump shot and rebounding is revealed. However, there are few previous studies focusing on the gaze behavior during ball non-possession.

The purpose of this study is to clarify the gaze behavior of skilled basketball players when they do not have a ball in offense comparing unskilled players.

METHODS: The subjects were six male students who belonged to the Hokkaido University mens basketball first division league as skilled players and six general male students who did not specialize in basketball as unskilled players. The subject players played half-court 3vs3 games wearing the eye tracker (Tobii Glasses 3). We analyzed the number of gazing targets, number of gazes, and gazing time regarding players gazing behavior when they were not in possession of the ball. Data were statistically compared between skilled and unskilled players.

Results and discussion:

Skilled players tend to look at the empty space, teammates, and defense more often than unskilled players. In addition, skilled players shifted their gaze fast, and obtained a lot of visual information by looking at more objects even in the same time. On the other hand, unskilled players tended to look at the ball holder. In a study by Ishibashi et al. (2010), it is reported that unskilled players tend to place their gaze on the ball, and the rate of skilled players placing their gaze on the ball is low. As a result, unskilled players received fewer passes and took fewer shots at the goal than skilled players. From this, it is consider that the ball holder does not contain important clues to run into the space and get a pass.

ACUTE EFFECT OF DYNAMIC BALANCE SHOOTING TRAINING ON DYNAMIC BALANCE IN MALE BASKETBALL PLAYERS

BOONSOM, N., BUNGMARK, W.

SILPAKORN UNIVERSITY

INTRODUCTION: In a dynamic game of basketball that changes by the instant, athletes need to be conditioned to sustain the highly stressful workloads experienced during practice or a game. Shooting goals is the most important skill to indicate the ability of the athletes and team. Because a team who can shooting more goals would be more likely to win. Especially jumping shot is the most common goal scored during a game of basketball. While the jumping shot athletes who can maintaining balance will lead to power and timing control in basketball shooting. From these reasons we are

interested to study acute effect of dynamic balance shooting training on dynamic balance in male basketball players. This study aims to study acute effect of dynamic balance shooting training on dynamic balance in male basketball players.

METHODS: Volunteers were 10 university students who learn basketball for general education at Silpakorn University (mean age 19±1.3 years). Training 8 exercises of dynamic balance, 5 repetitions per set, 3 sets. First set at an angle of 15 degree with the hoop, second set at an angle of 45 degree with the hoop and third set at an angle of 90 degree with the hoop. Before and after participating in the training program, the volunteers must evaluate the dynamic balance by Y-balance test.

RESULTS: Y-balance test before and after dynamic balance shooting training with 8 exercises (One foot touch (right), One foot touch (left), Front lunge, Jump front, Lunge lateral, Jump right, Jump left and 180 degree jump turn), 5 repetitions per set, 3 set. We found that after dynamic balance shooting training can increases anterior reach of right leg from 74.1±8.7 to 78.8±10.3 cm. and posterior reach of left leg from 87.6±17.1 to 97.8±12.66 cm. When analyzed statistically with pair t-test were significant at level .05.

CONCLUSION: Balance is important for basketball shooting skills. Dynamic balance shooting training can increased anterior reach and posterior reach in dynamic balance by a short time. Further study should study for long-term effect of dynamic balance shooting training on dynamic balance and jumping shot performance in basketball players.

CHANGES IN POST-SEASON BODY COMPOSITION AND ATHLETIC PERFORMANCE IN ELITE LEVEL MALE MOGULS ATHLETES FOLLOWING A CYCLE-INTEGRATED NEUROMUSCULAR TRAINING INTERVENTION

LIU, Y., YUAN, X.

BEIJING SPORT UNIVERSITY

INTRODUCTION: The aims of this study were to analyze overall and local body composition changes throughout the competition season using dual X-ray absorptiometry (DXA), to assess improvements in post-season athletic performance indices, and to examine the relationship between changes in body composition and changes in athletic performance, following the implementation of a cyclical integrated neuromuscular training programme for elite male moguls athletes of the Chinese national training team.

METHODS: Preseason and postseason DXA scans and performance data from the 2022–2023 season were retrospectively collected for 10 athletes.Body composition parameters included total and regional fat mass, lean mass, and body fat percentage, while athletic performance measures encompassed the standing triple jump on one leg, 30m dash, and 3000m run. The sport-specific test involved timing an athletes skate across 10 moguls, recorded in the field with a high-speed camera. All variables were quantitative and analyzed using paired t-tests or their nonparametric equivalents, with an alpha level of $p<0.05$ determining significance.

RESULTS: After a cycle of integrative neuromuscular training intervention, athletes exhibited significant decreases in fat mass($F=3.863$;$P=0.012$;effect size=0.584)and increases in lean mass in various body regions($P<0.05$), and total body measurements ($F=4.735$,$P<0.01$;effect size=0.784), While athletes demonstrated a significant decrease in the time required to skate across 10 moguls at the seasons end($F=6.757$, $P<0.01$;effect size=0.584), no significant differences were observed in other performance metrics($P>0.05$). Moderate correlations were noted between changes in body composition (total fat mass（$r=-0.684$, $P<0.01$）and total lean mass（$r=-0.574$, $P<0.01$）) and changes in athletic performance.

CONCLUSION: Cycle-integrated neuromuscular training can effectively shorten the skating time, increase lean body mass and reduce body fat content of moguls athletes, and there is a moderate correlation between body composition and athletic performance.This study offers a novel longitudinal assessment of body composition and athletic performance for elite male moguls athletes, aiding trainers and coaches in understanding seasonal variations in these variables and better preparing athletes for competitive success.

VALIDATION PROCESS OF GPS AND IMU TO DESCRIBE HIGH INTENSITY ACCELERATION AND DECELERATION IN FOOTBALL: A METHODOLOGICAL SYSTEMATIC REVIEW

DI CLAUDIO, C., CONTE, D., FANCHINI, M., SHARP, C., CAPRANICA, L.

UNIVERSITY FORO ITALICO OF ROME, AS ROMA FOOTBALL CLUB, UNIVERSITY OF VERONA, UNIVERSITY OF DENVER U.S.A.

INTRODUCTION: Football players are required to perform intermittent and multi-directional high-intensity accelerations and decelerations (HIAD), which impacts the players performance (1). Among various technologies to assess HIAD in football (2-3), Global Positioning System (GPS) devices and Inertial Measurements Units (IMU) embedded into GPS are often used to monitor the football players' activities. The present systematic literature review aims to investigate the validity, reliability and responsiveness of HIAD metrics commonly used in football.

METHODS: A systematic search of scientific articles published from January 1990 to March 2023 was conducted in three databases (PubMed, Web of Science and SPORTDiscus). Inclusion criteria were: full text in English; inclusion of information regarding the validity, reliability, and responsiveness of GPS and IMU of HIAD metrics. The study selection was performed by two independent authors assessing titles, abstracts and full text. The methodological quality of eligible studies was performed using the COSMIN checklist, therefore each study was rated on a 4-point scale: "very good", "adequate", "doubtful", "inadequate", and the lowest rating per measurement property was consider as quality outcome (4).

RESULTS: Out of a preliminary list of 152 studies, 15 papers met the inclusion criteria and an additional 7 studies were identified through a snowballing technique, resulting in a total of 22 studies. Findings revealed 8 studies examining validi-

ty (construct validity: n=2; criterion validity: n=6). The construct validity studies focused on IMU metrics (i.e. player load) and showed a lack of gold standards, despite their "very good" methodological quality. Radar guns, timing gates and portable gas analyzer were used to validate peak acceleration/deceleration and metabolic power metrics in the criterion validity studies, with five showing "very good" methodological quality and one "doubtful". Reliability was investigated in 17 studies with 2 rated as "adequate", 13 as "doubtful", and 2 as "inadequate" in methodological quality. The unclear stability of the participants, the time interval, and the conditions during the test and re-test procedures, negatively affected the methodological quality of the "inadequate" studies. Finally, no studies investigated the metrics' responsiveness.

CONCLUSION: The present systematic review generally highlights inconsistent methodological quality for both validity and reliability studies, which should caution sport scientists and football coaches in interpreting the collected HIAD metrics when monitoring daily practice. Therefore, further investigations are warranted to provide thorough validity, reliability and responsiveness of HIAD metrics in football.

CP-PN07 Thermoregulation and heat stress

THE EFFECTS OF REPEATED COLD- AND HOT WATER IMMERSION AFTER MUSCLE DAMAGE IN WOMEN: A RANDOMISED CONTROLLED TRIAL

WELLAUER, V., CLIJSEN, R., BIANCHI, G., HOHENAUER, E.

UNIVERSITY OF APPLIED SCIENCES AND ARTS OF SOUTHERN SWITZERLAND

INTRODUCTION: Exercise-induced muscle damage (EIMD) can result from unaccustomed or high-intensity eccentric exercise and is typically evaluated using objective and subjective markers of recovery. Cold- and hot water immersion (CWI and HWI, respectively) have emerged as potential post-exercise recovery interventions to accelerate recovery between training sessions or competitive events, but there is still a lack of evidence, especially in the female population. Therefore, this study aimed to evaluate the acute physiological changes and assess the effectiveness of repeated CWI and HWI in enhancing recovery in women compared to a passive control group (CON).

METHODS: 30 healthy women (23.4 ±2.9 years), randomly assigned to CWI, HWI or CON groups, completed a standardised EIMD protocol. Immediately and 120min after the EIMD, participants underwent a 10min recovery intervention (CWI, HWI, or CON). To assess acute physiological responses, muscle oxygen saturation (SmO2), core and skin temperature were recorded at baseline, after muscle damage, directly after the recovery intervention (postInt) and during a 30min follow-up period. Recovery was evaluated by assessing maximal voluntary isometric contraction of the knee extensors, muscle swelling, delayed onset of muscle soreness, and creatine kinase at baseline, 24, 48 and 72h following EIMD.

RESULTS: SmO2 was significantly lower in CWI than HWI (20min: 67.8 ± 2.7% vs. 74.7 ± 3.2%, $p = .006$; 30min: 64.4 ± 6.4% vs. 74.4 ± 3.9%, $p = .001$) and CWI compared to CON (20min: 73.5 ± 6.6%, $p = .026$; 30min: 73.0 ± 6.1%, $p = .006$). Core temperature was significantly higher in HWI compared to CWI at postInt and 30min (both $p < .01$) and compared to CON at postInt and throughout 30min follow-up (all $p < .05$), while there was no difference ($p > .05$) between CWI and CON. Skin temperature was significantly reduced in CWI compared to HWI (all $p < .001$) and compared to CON (all $p < .05$) between postInt and 30min follow-up. No significant differences were observed between CWI and HWI in objective and subjective markers of recovery throughout 72h follow-up.

CONCLUSION: Despite acute physiological changes, neither CWI nor HWI improved subjective and objective recovery characteristics during a 72h follow-up period compared to the CON group.

EFFECTS OF HIGH-CONCENTRATION CO2-WATER IMMERSION ON CORE BODY TEMPERATURE AND SLEEP CONDITION.

IWATA, R., NAKAMURA, M., TAKAHASHI, S., TAMAI, S., SASADAI, J., SHIMIZU, R., FUKAMI, K., SHOJI, R., NAKAJIMA, K.

JAPAN INSTITUTE OF SPORTS SCIENCES

INTRODUCTION: Compared to tap water immersion, CO2-water immersion is expected to increase oxygen supply through vasodilation, decrease pain, enhance immunity, and increase parasympathetic nerve activity (1,2). Therefore, CO2-water immersion has been used in our support centers to promote recovery in athletes. However, the effects of CO2-water immersion on recovery after training or consecutive games have not been reported. The purpose of the present study was to clarify the effects of CO2-water immersion on core body temperature, sleep condition, and fatigue in college athletes after training.

METHODS: In a crossover design, ten male college baseball players completed three trials: CO2-water immersion (CO2), tap water immersion at 40 °C (HOT), and seated at room temperature (25 °C) (CON) for 15 min after regular training. Partic-

ipants wore Actiwatch sleep monitors on their wrists on the night of the experiment to evaluate their sleep state. Core temperature (Tcore) was measured throughout the night until the morning of the next day.

RESULTS: The maximum Tcore showed moderately higher values (d = 0.534, p = 0.541) in the CO2 trail (38.12 ± 0.50 °C) than in the HOT trail (37.86 ± 0.48 °C). The CO2 and HOT trials exhibited mostly higher values (d = 1.852, p = 0.004 and 1.238, p = 0.032, respectively) than the CON trail (37.38 ± 0.27 °C). Minimal variations were observed in sleep duration (CO2, 5.76 ± 1.1 h; HOT, 5.42 ± 1.1 h; and CON, 5.93 ± 1.0 h), and the effect size was small (d < 0.5). Sleep efficiency and quality of sleep were moderately higher in the CO2 trail than in the HOT trail (d = 0.577, p = 0.574 and 0.512, p = 0.669, respectively). The difference between the Tcore at sleep onset and the maximal Tcore was slightly greater (d = 0.364, p = 0.497) in the CO2 trail (-0.94 ± 0.54 °C) than in the HOT trail (-0.78 ± 0.32 °C).

CONCLUSION: CO2-water immersion increased core body temperatures more significantly than hot tap water immersion at 40 °C. These increased temperatures resulted in positive effects on sleep efficiency and sleep quality, which may be due in part to the significant decrease in core body temperature at the time of sleep onset.

ECCENTRIC MUSCLE-DAMAGING EXERCISE IN THE HEAT LOWERS CELLULAR STRESS PRIOR TO AND IMMEDIATELY FOLLOWING FUTURE EXERTIONAL-HEAT EXPOSURE

DUNN, R., LUK, H., APPELL, C.R., JIWAN, N.C., KEEFE, M.S., SEKIGUCHI, Y.

TEXAS TECH UNIVERSITY

INTRODUCTION: Bouts of eccentric muscle-damaging exercise or heat exposure have the potential to reduce physiological and cellular stress during future exertional-heat exposure. Given potential cross adaptations, this study investigated the effect of muscle-damaging exercise in the heat on reducing physiological and cellular stress during future exertional-heat exposure.

METHODS: Ten healthy, physically active males (mean ± SD; age, 23 ± 3 years; body mass, 78.7 ± 11.5 kg; height, 176.9 ± 4.7 cm) completed this study. In a randomised, counterbalanced order, participants were assigned into two groups; a) downhill running (DHR) in the heat (ambient temperature [Tamb], 35°C; relative humidity [RH], 40%), and b) DHR in thermoneutral (Tamb, 20°C; RH, 20%) to evoke muscle damage. Seven days following DHR, participants performed a 45-minute flat run in the heat (FlatHEAT [Tamb, 35°C; RH, 40%]). During exercise trials, heart rate (HR) and rectal temperature (Trec) were recorded at baseline and every 5-minutes. Peripheral blood mononuclear cells were isolated and homogenised to assess heat shock protein 72 (Hsp72) concentration between conditions at baseline, immediately post-DHR, and immediately pre- and post-FlatHEAT.

RESULTS: Mean Trec during FlatHEAT between hot (38.23 ± 0.38 oC) and thermoneutral (38.26 ± 0.38 oC) were not significantly different (p = 0.68), with no mean HR differences during FlatHEAT between hot (172 ± 15 beats.min-1) and thermoneutral (174 ± 8 beats.min-1; p = 0.58). Hsp72 concentration change from baseline to immediately pre-FlatHEAT was significantly lower in hot (-51.4%) compared to thermoneutral (+24.2%; p = 0.025), with Hsp72 change from baseline to immediately post-FlatHEAT also lower in hot (-52.6%) compared to thermoneutral (+26.3%; p = 0.047).

CONCLUSION: A singular bout of muscle-damaging exercise in the heat reduces cellular stress levels prior to and immediately following future exertional-heat exposure. Individuals regularly exposed to exertional-heat stress (e.g., athletes, military personnel, and firefighters) would likely benefit from implementing this preconditioning modality during heat preparation, particularly when the window to perform more robust heat adaptation methods is insufficient (e.g., heat acclimation/acclimatisation).

EFFECT OF HEAT ACCLIMATION ON PERFORMANCE IMPROVEMENTS IN COOL TEMPERATURE CONDITIONS: A PILOT STUDY

KEEFE, M., DUNN, R., SEKIGUCHI, Y.

TEXAS TECH UNIVERSITY

INTRODUCTION: Training and competing in the heat negatively impact athlete performance and health. Heat acclimation (HA) involves repeated heat exposures that many endurance athletes use to optimize performance and safety when competing in the heat. Although HA has been shown to improve endurance performance in the heat, contention remains whether it may confer these adaptations to a cool environment. Thus, the purpose of this study was to investigate physiological and performance adaptations in a cool environment following HA in endurance athletes.

METHODS: Seven high-level endurance runners (6 females [age: 20±2 years; body mass: 62.05±5.81 kg; maximal oxygen uptake [VO2max], 61.52±7.21 mL·kg-1·min-1], 1 male [age, 19 years; body mass, 66.80 kg; VO2max, 79.60 mL·kg-1·min-1]) participated in this pilot study. As a baseline assessment, participants completed a VO2max test, followed by an 8-kilometer time-trial (TT) in cool conditions (ambient temperate [Tamb], 11°C; relative humidity [RH], 40%). Following this, participants completed a 7-day training protocol consisting of 60-minutes running at 50% velocity at VO2max in either a thermoneutral (n = 3; Tamb, 22°C; RH, 40%) or hot condition (n = 4; Tamb, 40°C; RH, 35%). Physiological variables (i.e.,

core temperature [Tc], sweat rate [SR], plasma volume [PV]) were assessed on days 1 and 7 to determine HA adaptations. A post-testing visit was conducted to determine performance (VO2max, lactate threshold [LT], TT) changes. A two-way repeated measures ANOVA was conducted to assess physiological and performance changes from pre- to post-testing for performance variables, and from days 1 to 7 for physiological variables, between conditions. Cohen's d classification of effect sizes was calculated to determine small (0.20-0.50), medium (0.50-0.80), and large (>0.80) effects.

RESULTS: No significant differences were identified for physiological variables (i.e., Tc, SR, and PV) between days 1 and 7 in both conditions (ps > 0.05), however, large effects for SR (d = 0.95), and small effect sizes for Tc (d = 0.20) and PV (d = 0.18) were observed in the heat condition. The thermoneutral condition experienced small effect sizes for Tc and SR (d = 0.06-0.37), and a medium effect size for PV (d = 0.51). Similarly, there were no significant improvements in performance metrics (i.e., VO2max, LT, and TT) from pre- to post-training between conditions (ps > 0.05). In the heat condition, LT and VO2max demonstrated medium effect sizes (d = 0.51-0.63), but TT (d = 0.08) resulted in a small effect size. For the thermoneutral condition, LT, VO2max, and TT demonstrated small effect sizes (d = 0.00-0.19).

CONCLUSION: The present findings indicate that heat acclimation may procure the necessary adaptations to improve endurance performance in cool temperatures. Caution should be taken when interpreting these findings due to the nature of pilot data analyzed. This research was supported by a World Athletics Research Grant from the American College of Sports Medicine.

INVESTIGATING THE MECHANISMS OF A NAP AND THE EFFECTS ON SUBMAXIMAL PERFORMANCE, FOLLOWING TWO NIGHTS OF PARTIAL SLEEP RESTRICTION

GALLAGHER, C., GAINTATZIS, A., LAMB, E., MCDONALD, M., PULLINGER, S.A., EDWARDS, B.J.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: We investigated the effects of partial sleep deprivation (3 h for two consecutive nights, retiring at 03:30 and waking at 06:30h) on the thermoregulatory responses during a nap at 13:00h and the effect on submaximal weight-lifting at 17:00.

METHODS: Eight resistance trained males (22.8±2.1 years; 177.8±5.9 cm; 82.8±12.2 kg) participated in this study. Prior to the experimental protocol, one repetition max (1RM) for bench press and back squat, normative habitual sleep and food intake were recorded. Three familiarisation sessions were completed by all participants prior to testing. All conditions were separated by 7 days with trial order counterbalanced. Participants completed three experimental conditions which all required the participant to follow two consecutive nights of partial sleep deprivation prior to the testing day. Actimetry was used to monitor sleep and protocol compliance over these two nights. On the third day at 13:00h participants either reclined: 1) at 45 degrees in a hospital bed for 60-min remaining awake and able to read in ambient lighting of 250 Lux (PSR0), 2) in a supine position for 30min in complete darkness and attempt to sleep (PSR30), 3) in a supine position for 60 min in complete darkness and attempt to sleep (PSR60). During the testing session at 13:00h, rectal and skin temperature variables (7-sites) were monitored. At 17:00h participants completed three repetitions of left-and right-hand grip strength, followed by an active warm up and dynamic stretching. Three repetitions at 40, 60 and 80% of the individuals 1RM value, for bench press and back squat were then undertaken. MuscleLab linear encoders were attached perpendicular to the Olympic bar to record performance variables (average power, average velocity, peak velocity, and displacement).

RESULTS: Data were analysed using a general linear model with repeated measures. No significant main effect was reported for conditions for all MuscleLab variables, for both bench press and back squat. There was a significant main effect for RPE breathing values for bench press (P=0.046), with greater mean values in the PSR0 condition compared to both PSR30 and PSR60. A significant main effect for load was identified across all Musclelab variables and RPE, whereby perceived exertion increased with greater load on the bar. We report a significant effect for retiring time (Fell asleep) for actimetry variables, with an earlier retiring time on the second night of partial sleep deprivation (P=0.041). No significant effect was reported for absolute and relative Trec, however there was a significant main effect of condition (P<0.001; ES=0.952; Power=1.00) for time point of temperature gradient (Trec–Tskin).

CONCLUSION: In summary, heat-loss mechanisms during a nap are greater at 30 than 60 min, although this did not translate to an improvement in submaximal performance.

GIG WORKERS' WORKLOAD AND PHYSIOLOGICAL STRAIN: A CASE OF THE PARCEL DELIVERY WORKERS IN SOUTH KOREA

LIM, G., TAN, P., KWEK, J.H., TRAN, T., LEOW, C.H.W., LEE, J.K.W., LEE, J.Y.

HEAT RESILIENCE AND PERFORMANCE CENTRE, NATIONAL UNIVERSITY OF SINGAPORE

INTRODUCTION: Despite the increasing number of parcel delivery workers' fatalities and injuries, there have been few comprehensive investigations into the workers' occupational health risks. This study aimed to quantify delivery workers' workload, assess their physiological strain, and investigate the impact of workload on their physiological strain.

METHODS: A total of forty male delivery workers from two logistics work sites in South Korea (site A and site B) participated in this study. Wet Bulb Globe Temperatures (WBGT) at each site were measured throughout the work shifts. Workload, work environment, and workers' dietary behaviors were investigated through in-depth interviews and wearable devices. Workload was quantified using working hours per day, workdays per week, the number of parcels, and total step count on the measurement day. Workers' body core temperature (Tc), heart rate (HR) and step count were continuously recorded throughout their shifts, while body mass was measured at four timepoints: pre-shift, mid-shift, post-shift, and the next morning. Urine specific gravity (USG) was measured pre-shift and the next morning.

RESULTS: Mean WBGT was below 20°C throughout the work shifts. The workers worked 11.7 hours per day on average and 5–7 days per week. The number of parcels they delivered on the measurement day ranged from 150 to 571 and step counts ranged from 14,400 to 38,068. Regarding nutrition, 45% of the workers skip both breakfast and lunch on busy days, with 25% skipping both meals every working day. 32.5% of the workers' maximum Tc exceeded 38°C, which is the upper limit of the Threshold Limit Values® for heat stress from the American Conference of Governmental Industrial Hygienists guidelines. 47.5% of the workers exceeded 80% of their age predicted maximum HR during their shift. 87.5% of the workers showed a decrease in their body mass after their shifts and 25% lost more than 2 kg. Categorizing dehydrated workers as those with 1.025 or greater values of USG, 15% and 17.5% were dehydrated in the pre-shift and next morning timepoints, respectively. The number of parcels delivered by the workers showed significant correlations with both peak HR (Pearson's R = 0.499, p = 0.035) and their body mass loss (Pearson's R = 0.665, p = 0.001) for site A. Total step count also displayed a significant correlation with the maximum value of workers' Tc for site A (Pearson's R = 0.484, p = 0.036). No significant correlation between workload and physiological responses was found for site B in this study.

CONCLUSION: The results of this study demonstrated that workers' workload may be related to their physiological strain. This study suggests that heat-preventive measures, such as appropriate work-rest cycles, may be beneficial to the physical health of parcel delivery workers. Future research might further investigate workers' nutrition and hydration, the effect of extreme temperature conditions on physiological strain, as well as the impact of workload on workers' performance.

EFFECTS OF PRE-COOLING ON PHYSICAL PERFORMANCE, VO2PEAK, %VO2PEAK UTILIZATION, AND THE VO2 KINETICS DURING CYCLING EXERCISE PERFORMED IN A HOT ENVIRONMENT

PRADO, L., MAIA-LIMA, A., GORDON, D., MERZBACH, V.
FEDERAL UNIVERSITY OF MINAS GERAIS

INTRODUCTION: Physical performance during prolonged exercise performed in hot environments tends to be reduced when compared to those carried out in temperate environments. Several strategies have been proposed in an attempt to mitigate the harmful effects of hot environmental conditions on physical performance, and one of the most popular among them is pre-exercise body cooling. However, there is no consensus on which are the main mechanisms involved in its already well-established ergogenic effect.

METHODS: This study examined the effects of pre-cooling on physical performance, VO2PEAK, %VO2PEAK utilization, and the VO2 kinetics during a cycling exercise performed in a hot environment. Four men and four women cycling athletes (age 39.75 ± 10.25 years, VO2MAX 52.39 ± 8.74 ml.km-1 .min-1, body mass 65.66 ± 6.37 kg, 16.77 ± 6.86% body fat) volunteered for this study. The participants performed 03 exercise trials – an exercise bout in a temperate environment (20° C, 41% RH; TEMP), an exercise bout in a hot environment (34° C, 60% RH; HOT), and an exercise bout in a hot environment preceded by a precooling intervention through full-body water immersion (PREC). Each exercise trial was composed of 04 sets of cycling separated by a 05-minute rest interval. Each set consisted of 06 minutes of fixed-intensity exercise in a moderate domain, 09 min of self-paced exercise, and 1.5 minutes of performing in the same peak power output that was recorded in the previous VO2max testing.

RESULTS: Precooling attenuated the decrease in distance covered observed in the HOT condition when compared to TEMP. This physical performance improvement in the PREC condition was associated with prevention in the VO2PEAK reduction seen in the HOT condition, the lower heart rate values observed during the moderate intensity phase, and lower core temperature when compared to the HOT condition. The %VO2PEAK utilized during the self-paced phase did not differ between HOT and PREC conditions but was lower in these situations when compared to TEMP. VO2 kinetics was enhanced during the first set in the hot environment, and precooling prevented this effect. Precooling did not affect skin temperature, thermal comfort, reported perceived exertion, water intake, or sweat rate during the exercise.

CONCLUSION: In conclusion, precooling attenuated the distance covered reduction observed in the hot environment when compared to the exercise performed in a temperate environment. Physical performance enhancement was associated with a reduction in cardiovascular strain but not with an alteration in %VO2PEAK utilized. Precooling prevented the VO2 kinetics acceleration seen at the first set in the hot environment.

CP-AP13 Statistics and Analyses

CRACKING THE CODE: PREDICTING PLAYER POSITIONS IN HANDBALL WITH MACHINE LEARNING

VENZKE, J., SCHÄFER, R., MANCHADO, C., PLATEN, P.
RUHR-UNIVERSITY BOCHUM

INTRODUCTION: In team sports, an increasing amount of data is being collected to assess tactical behavior and monitor physical performance. Strong physical performance is a cornerstone of success in professional team sports. An individual or position-specific performance profile is highly desired by coaches for player monitoring. However, many analyses focus on selected parameters to describe position specific exercise load. A comprehensive understanding of player performance requires the consideration of multiple parameters. However, coaches are faced with an overwhelming number of parameters and require a more detailed view of the most meaningful parameters.

Our aim is to identify the most influential predictor of locomotion data across different positions in handball.

METHODS: A supervised machine learning model was used to classify positions with 10-fold cross validation. Our analysis included several conventional parameters (distance, mean velocity, speed/acceleration zones) and parameters derived from the metabolic power approach (energy cost, metabolic power). Local positioning system data (Kinexon Precision Technologies) from all 65 EHF EURO 2020 matches were used. 414 elite male handball players were included, resulting in 1596 datasets. We analyzed net playing time with durations longer than 1 min. Goalkeepers were excluded.

RESULTS: 1437 datasets were used for training and validation and 159 for testing. The test accuracy of our model was determined to be 78.6%. Wings were the most accurate position to predict, with 80 out of 81 players correctly predicted. Center backs were often confused with outer backs. Pivots were also often predicted as outer backs. Average speed had the greatest relative influence on predicting position (47.4%) and weight the second greatest (31.2%), followed by average metabolic power (5.2%) and height (4.9%).

CONCLUSION: Our study highlights the importance of using multiple parameters to accurately classify player positions in elite handball. Our model demonstrated robust performance, as evidenced by high accuracy on the test dataset. Wings consistently stood out as the most accurately predicted positions, reflecting their typically lower body weight. Average speed being the best predictor is consistent with recent research showing positional differences in average speed (Manchado et al., 2022). For example, wing players cover the most distance and spend the most time in the high-speed categories. These findings highlight the potential of machine learning techniques to improve our understanding of player performance dynamics in team sports such as handball.

EMERGING TRENDS AND KNOWLEDGE STRUCTURES ON SOCCER RESEARCH: A SCIENTOMETRIC ANALYSIS

LUO, H., NASHARUDDIN, N.A., TENGKU KAMALDEN, T.F., ZHU, X.L., XIANG, C.Q.

UNIVERSITI PUTRA MALAYSIA, NATIONAL SPORTS INSTITUTE , SHENZHEN TECHNOLOGY UNIVERSITY

INTRODUCTION: The sport of soccer has received increasing attention and sparked multidisciplinary exploration. There is a lack of comprehensive scientometric analyses of this change over time. Our objective is to understand emerging trends and knowledge structures in the field of study through scientometric analyses.

METHODS: The scientometric scrutiny conducted in this investigation was underpinned by the Web of Science Core Collection as the designated database. The search strategy encompassed the employment of the following query: TS= ("football" OR "soccer"). The ambit of citation indexing was confined to SCI-E, SSCI, and A&HCI indices. Within the spectrum of document classifications, exclusivity was accorded to entries categorized as Article or Review Article. The temporal scope spanned from December 1, 2003, to December 1, 2023, with an absence of linguistic constraints. Redundancies were expunged utilizing the CiteSpace tool, culminating in a corpus of 9069 unique documents, subsequently imported into CiteSpace version 5.7.R5 for ensuing analysis.

RESULTS: The five most cited references within this dataset were as follows: Gabbett TJ, 2016, titled "The training—injury prevention paradox: should athletes be training smarter and harder?". Ekstrand J, et al., 2011, titled "Injury incidence and injury patterns in professional football: the UEFA injury study". Ekstrand J, et al., 2016, titled "Hamstring injuries have increased by 4% annually in mens professional football, since 2001: a 13-year longitudinal analysis of the UEFA Elite Club injury study". Rampinini E, et al., 2009, titled "Technical performance during soccer matches of the Italian Serie A league: Effect of fatigue and competitive level". Hopkins W, et al., 2009, titled "Progressive statistics for studies in sports medicine and exercise science". The five most cited journals were the Journal of Sports Sciences, Sports Medicine, Medicine & Science in Sports & Exercise, Journal of Strength and Conditioning Research, and British Journal of Sports Medicine. The United States was the country with the highest number of publications and citations, followed by the United Kingdom, Australia, Spain, and Brazil. The top five most cited institutions were Liverpool John Moores University, Victoria University, Australian Catholic University, Edith Cowan University, and University Technology Sydney. The top 5 authors with the highest number of total citations in our dataset were Hopkins WG, Bangsbo J, Reilly T, Rampinini E, and Gabbett TJ.

CONCLUSION: This study reveals three prominent and discrete general research trends that have occurred over the last five years. These trends were denoted as "training load and athlete monitoring," "sports injury risk and prevention," and "sports performance and analysis". This study identified emerging trends and knowledge structures in the field of soccer research. These findings can inform the future direction of funding agencies and research groups.

QUANTIFYING MATCH TIME REQUIRED FOR RELIABLE IN-SITU PROFILING IN RUGBY UNION PLAYERS.

MAVIEL, C., COUDERC, A., DUCHÉ, P., MORIN, J.B., VERCRUYSSEN, F.

UNIVERSITÉ DE TOULON

INTRODUCTION: The force-velocity profile (P-FV) is commonly used to assess sprint-related physical qualities in sports, to orient training based on athletes performance. However, this method has limitations, particularly the inability to gather physical engagement's information under actual match conditions in rugby. In this context, the use of Global Position System (GPS) technology has paved the way for collecting in-situ acceleration and speed data during rugby matches. Morin et al.[1] have introduced an in-situ method using GPS to generate an Acceleration-Speed (AS) profile conceptually close to the P-FV [2]. It is therefore crucial to understand players profiles in a match within a minimal time frame to avoid the confounding measures relative to the effects of training. This study aims to determine the saturation point of the AS profile in-match for rugby players, to provide a precise minimal time window for obtaining a meaningful AS profile in a match situation.

METHODS: The playing time of 25 professional rugby players was recorded using GPS technology and segmented into four groups from 40 to 160 minutes of play. The analysis was conducted over 8 official matches during a period of 49 days. This segmentation enabled the gradual incorporation of data into the AS profile analysis. For each interval, the impact of integrating new match data on the AS profile outputs was assessed, aiming to identify the saturation point where additional data did not induce significant changes and thus, altered the profile. A repeated measures ANOVA was applied, and the significant differences were then explored using Bonferroni post-hoc tests, allowing for detailed comparisons between time windows.

This methodology led to identifying the saturation point for theoretical maximum acceleration (A0) and maximum acceleration (S0), namely the threshold beyond which adding new gameplay data in the analysis does not result in statistically significant changes in these parameters.

RESULTS: The ANOVA revealed a significant effect under all tested conditions with a loss of statistical significance from 120 minutes of play for acceleration ($p = 0.12$) and speed ($p = 0.15$), with an intra-subject variability of 3.29% for A0 and 1.99% for S0. Beyond 160 minutes, a lack of significant effect was observed for A0 ($p = 1.00$) and S0 ($p = 0.99$), with an intra-subject variability of 1.51% for A0 and 1.20% for S0.

CONCLUSION: These findings indicate that the significant effect is not observed after 120 minutes of play, despite an important intra-subject variability. However, beyond 160 minutes, this variability is reduced, suggesting a clear saturation point. Therefore, it is recommended for practitioners to use 160 minutes of actual match play (equivalent to about 2 complete games), to derive a reliable AS profile.

EFFECT OF THE AWAY GOAL RULE ON THE TECHNICAL PERFORMANCE OF FOOTBALL TEAMS IN THE UEFA CHAMPIONS LEAGUE

KUBAYI, A., STONE, J.

TSHWANE UNIVERSITY OF TECHNOLOGY

INTRODUCTION: Despite significant debate surrounding UEFA's removal of the away goal rule in 2021, its impact on technical performance has not been studied. Therefore, this study aimed to investigate how selected technical performance indicators were impacted by the change in the away goal rule during the UEFA Champions League.

METHODS: Data were sourced via the Wyscout platform. The sample consisted of 112 UEFA Champions League games played during the knock-out stages of the competition, in which 56 games were played during seasons with an away goal rule (2017–2018 and 2018–2019) and 56 were played in seasons without an away goal rule (2021–2022 and 2022–2023).

RESULTS: The findings showed that the removal of the away goal rule was accompanied by significant ($p < 0.05$) decreases in average pass length, long passes, progressive passes, passes to the final third, offsides, duels, duels won, and counterattacks. Furthermore, a significant ($p < 0.05$) interaction was found between the away goal rule and the leg of competition, affecting the number of counterattacks with shots.

CONCLUSION: Therefore, UEFA should take cognisant of the present findings when considering the use of the away goal rule in future competitions.

EFFECTS OF CHANGES IN DEFENSE STRATEGY ON OPPONENTS OFFENSIVE PERFORMANCE IN BASKETBALL

OGISO, G., KITAMURA, M., KAMIBAYASHI, K.

DOSHISHA UNIVERSITY

INTRODUCTION: In basketball, there has been extensive discussion about the effectiveness of changing defense systems mid-game. Such "changing defense" employs various defensive tactics during a game, such as man-to-man defense and zone defense, with the aim of catching their attacking opponent by surprise.

In fact, this strategy is commonly utilized not only at world tournaments such as the Olympics and the World Cup but also at the university level in Japan. However, the decision to implement changes in defense during a game often relies on subjective judgments of coaches and managers. Although there are numerous references to the changing defense in instructional books, including Smiths book [1], its effectiveness remains unclear without rigorous game analytics.

Therefore, this study aimed to quantitatively evaluate the effectiveness of changing defense on the opponents offensive performance in university mens basketball games held within the Kansai region (south-central part) of Japan.

METHODS: The analysis focused on closely contested games (defined as games with difference up to 8 points at the end of the third quarter and 12 points at the end of the game) in the first division of the 2021/22 Kansai region (south-central part of Japan) Student Basketball League. A total of 35 games met the analysis criteria. From the game video, we identified which of the four main defensive systems was employed for each ball possession: man-to-man defense, zone defense, press defense, or mixed defense. In addition, the number of passes and elapsed time to a shot were examined for each possession. Turnover percentage, free throw rate, and points per possession extracted from the four factors [2], as well as shot clock duration (evaluated as time taken to shoot) and the number of passes were averaged for the opponents

offenses against man-to-man defense, the opponents first offense after a change from man-to-man defense to a different defensive system, and the opponents second and third offenses after changing the defense.

RESULTS: The results revealed a statistical advantage associated with the changing defense: immediately after the changing defense, the opponents offense had more time to shoot, and the free throw rate dropped. In addition, it was numerically evident to induce opponents turnovers and reduce the expectation of scoring immediately after the changing defense.

CONCLUSION: The findings of the present study indicated the effectiveness of changing defense in limiting the opponents offensive performance, especially immediately after the change.

DATA VARIABLES RELATED TO WINS AND LOSSES OF GAME IN DIFFERENT SCENARIOS IN THE WNBA 2023 SEASON

DENG, Y., XU, X., LUO, B., LIN, F.
BEIJING SPORT UNIVERSITY

INTRODUCTION: The research subarea of sports performance analysis is in constant evolution, with a growing emphasis on the game data analysis. However, available research on womens basketball games is relatively scarce. Therefore, in this paper the author aims to explore the key variables that influence the game outcomes in the Women's National Basketball Association (WNBA) during the 2023 season.

METHODS: Firstly, chi-square tests and k-means clustering to control variables was applied to categorize games into four groups (home balanced, home unbalanced, away balanced, and away unbalanced). Secondly, stepwise regression and logistic regression were employed to identify key variables influencing game outcomes in each group.

RESULTS: In the home balanced group 8 variables including field goals made (FG) (+), field goal attempts (FGA) (-), 3-Point field goals made (3P) (+), free throw shooting made (FT) (+), total rebounds (TRB) (+), steals (STL) (+), turnovers (TOV) (-), and personal foul (PF) (-) were identified as key variables. Meanwhile, in the home unbalanced group 6 variables including FG (+), FGA (-), offensive rebounds (ORB) (+), STL (+), blocks (BLK) (+), and TOV (-), similarly away balanced group 8 variables including FG (+), FGA (-), FT (+), TRB (+), assists (AST) (+), STL (+), TOV (-), and PF (-), and in the away unbalanced group 4 variables including 3P (+), offensive rebound percentage (+), defensive rebound percentage (+), and total rebound percentage (+) were identified as key variables.

CONCLUSION: The most significant divergence observed occur in the away unbalanced group, while similarities are prominent between home and away balanced groups. Furthermore, these variables encompass both offensive and defensive aspects, contributing to a relatively balanced situation. This research enriches the understanding of the characteristics of key game variables in high-level womens basketball games.

THE INFLUENCE OF SERVE SPEED ON ITS EFFICIENCY IN THE EXAMPLE OF THE ESTONIAN HIGHEST LEAGUE VOLLEYBALL TEAM.

STAMM, R., STAMM, M., ESNA, A.
SCHOOL OF NATURAL SCIENCES AND HEALTH

INTRODUCTION: This work aimed to find out which serve speeds have the greatest influence on ball reception. Do the balls hit the fastest are more difficult for the receivers of the ball to receive?

METHODS: The research was carried out with the Selver/TalTech men's volleyball team who is playing in the highest league in Estonia. There were 15 players (3 middle blockers, 6 outside hitters, 3 setters, 1 opposite hitter, 2 liberos) aged 17 to 30 years and their mean height was 191 cm and mean weight was 80,26 kg. Altogether 818 serve speeds were measured together with the reception quality of the opponents during 10 matches in the Baltic League in 2022. Serve speed was measured by Pocket Radar SD2000 and the reception efficiency using the 5 balls scale according to the Data Volley program.

RESULTS: From the 818 served serves 61 went to the direct points (aces) and with the mistake ended 109 serves. The maximum speed of the serves was 109 km/h and the minimum speed was 42 km/h. Maximum speed was reached twice-once by the middle blocker and once by an outside hitter. The best ball reception scores were achieved by receiving the slowest serves.

CONCLUSION: The following conclusions can be drawn from the analyzed RESULTS: The success rate of inaccurate reception of the ball is increasing compared to the increase in the speed of the serve. We divided the serve speeds by standard deviation into three different classes (fast serves, medium serves, and slow serves) and compared slow serve receptions with fast serve receptions efficiency by mean values. And can conclude after the students' t-test that the efficiency for the receptions that followed the fast serves was statistically significantly lower than the receptions efficiency that followed slow serves ($p<0,01$).

The highest number of direct serve errors were made at the fastest serve speed, so the faster the serve, the higher the probability of a direct serve error. This agrees with Mercelino's work (Mercelino et al., 2008) which concluded that better teams are gathering the mistakes during the serves more, but they succeeded in earning direct points also more often.

The authors think that we still must take risks with high-speed serving because as Paulo's research concluded the direct points earned by the serves are correlated with winning the matches. (Paulo et al., 2017)

ASSESSING WHEELCHAIR TABLE TENNIS CLASSIFICATIONS: PERFORMANCE ANALYSIS AND CLASS CONSOLIDATION PROPOSAL

WU, S.K., SHEU, Y.H.

NATIONAL TAIWAN UNIVERSITY OF SPORT

INTRODUCTION: In the Paralympic Games, classification plays an important role in ensuring the fairness and credibility of competition. To provide an evidence-based classification in wheelchair table tennis, the objective measurement of wheelchair players with physical impairments is essential. The purpose of this study was to evaluate the current issues related to the classification of wheelchair classes in para table tennis through performance analysis. In theory, higher wheelchair classes should correlate with superior abilities and performance.

METHODS: We conducted an analysis of the world rankings of the top 50 wheelchair players, comparing them with the total number of world rankings for male players (N=310) and female players (N=115). Additionally, we used an intelligent racket to measure swing speed and efficiency in the maximal forehand swing stroke of 10 male players in the top 20 rankings (5 players in class 4 and 5 players in class 5), following the testing method outlined in the study by Sheu and Wu (2023).

RESULTS: The world top 50 ranking in wheelchair male players from classes 1 to 5 was 0 (0%), 2 (4%), 13 (26%), 23 (46%), and 11 (22%), respectively. For wheelchair female players, the rankings were 1 (2%), 6 (12%), 17 (34%), 15 (30%), and 11 (22%). Notably, players in classes 1 to 3 performed much weaker than classes 4 and 5. Using the intelligent racket to conduct 27 maximal strokes and maximal topspin swings, no significant differences in swing speed and efficiency were found between classes 4 and 5.

CONCLUSION: Contrary to the anticipated advantage of better trunk functions in class 5 players, our analysis of performance rankings and intelligent racket tests in wheelchair classes 4 and 5 did not reveal a significant performance difference. We propose the consolidation of classes 4 and 5 into a new category, thereby reducing the current five classes in wheelchair table tennis to four. Ensuring fairness in competition for wheelchair table tennis players requires careful consideration of new minimal impairment criteria for this proposed combined class.

TACTICAL AND TECHNICAL ANALYSIS OF MEN'S 800M RACES IN WORLD ATHLETICS CHAMPIONSHIPS

KADONO, H.

SENDAI UNIVERSITY

INTRODUCTION: In 800m running event, it is reported that the pacing strategy of world record was positive pacing [1], on the other hand there were various pacing strategies in Olympic games [2] and World Championships [3]. Tactical preparations that improve ability to change running speed and respond dynamically changes in speed are required for runners and coaches when they prepare for championship races. In running biomechanics, running speed, step frequency and step length are basic parameters which represent running technique. Previous studies focused on only paces (time or speed), but in this study focused on not only speed but also step frequency and time and aimed to investigate technical characteristics during men's 800m races in World Athletics Championships.

METHODS: This study used a digital video camera (Panasonic, HC-VX992, 60Hz) to videotape all heats of men's 800m (6 heats for 1st round, 3 heats for semi-final and a final) in the World Athletics Championships, Oregon 2022 (WC22). This study used official race analysis on the WC22 web site to classify all heats into positive pacing races (POS) and negative pacing races (NEG). POS was the heat that faster 1st lap, NEG was the heat that faster 2nd lap. First 2 finishers of each heat were picked out and they were classified into POS and NEG. Every 100m split times on the WC22 website were used to calculate average running speed of each 100m for 8 all sections. The video camera movies were used to measure the time which runner took 10 steps with their natural running form in each 100m section, followed by calculating average time which runner take a step. Step frequency (SL) in each 100m section was calculated by inverse step time, and step length (SL) was calculated by running speed divided by SF.

RESULTS: 6 of 10 heats were POS (n=12) and 4 of 10 heats were NEG (n=8). There was no significant difference in goal time between POS (1:45.32±00.56) and NEG (1:46.25±02.05). POS was significantly faster in 1st lap time than NEG ($p<0.05$, $d=1.248$), especially running speed was significantly faster (200-300m: $p<0.001$, $d=0.214$; 300-400m: $p<0.01$, $d=0.286$) and SF was higher (n.s.) in 200-400m. And SL was larger in 100-400m (n.s.). On the other hand, NEG was significantly faster in 2nd lap time than POS ($p<0.001$, $d=0.433$), especially running speed was faster (500-600m: $p<0.01$, $d=0.171$; 600-700m: $p<0.01$, $d=0.137$) and SF was higher (n.s.) in 500-700m. And SL was almost the same as POS in 400-800m.

CONCLUSION: There were both POS and NEG in WC22, and running speed, SF and SL were different between 2 types of pacing. In POS, it was faster in 200-400m with high SF and large SL. In NEG, it was faster in 500-700m with not large SL but

high SF. This study suggests that when runners and coaches do tactical preparation for championship races, they should take into account not only pace or speed but also techniques (changing SF and SL).

CURRENT STATUS OF ENDURANCE DIAGNOSTICS IN GERMANY: A QUESTIONNAIRE SURVEY

BÜTHE, E., VENZKE, J., SCHÄFER, R., PLATEN, P.
RUHR-UNIVERSITÄT-BOCHUM

INTRODUCTION: Performance diagnostics in endurance sports are indispensable tools in sports and medical research, providing precise insights into the physical capabilities, strengths, and weaknesses of athletes. A wide variety of methods are used worldwide to assess performance, including diverse threshold concepts, protocols, and standardisations. In order to assess the current state of performance diagnostics and to identify significant similarities and differences in methods within Germany, an online questionnaire survey was designed and distributed to various performance diagnostics institutions.

METHODS: The online questionnaire included the following categories: test procedures, protocols and load schemes, threshold concepts, standardisation, individualisation and training planning. The survey was completed by 40 sports diagnostic facility managers over a two-week period. Estimates and confidence intervals were derived using binomial distribution and Clopper-Pearson adjustment.

RESULTS: Regarding threshold concepts, 45% CI95% [29.3; 61.5] (18/40) of the respondents chose the individual anaerobic threshold according to Stegmann & Kindermann et al. (1981) or the aerobic-anaerobic threshold according to Mader et al. (1976). In 82.5% CI95% [67.2; 92.7] (33/40) of the cases, training recommendations were based on heart rate, whereas in 80% CI95% [64.3; 90.9] (32/40) they were based on speed/power. Regarding standardisation, in 72.5% CI95% [56.1; 85.4] (29/40) of the centres, changes in test conditions were not documented, when testing the same person twice. In 77.5% CI95% [61.6; 89.2] (31/40), no medical history was taken before the start of the test. Dietary considerations before testing, such as drinking, carbohydrate intake, or caffeine, were also not specified in 35% CI95% [20.6; 51.7].

CONCLUSION: These results indicate considerable variation between institutions in the choice of threshold concepts and the regulation of intensity and speed. The lack of documentation of changes in test conditions and the absence of discussion about personal clarification raise questions about standardisation and quality assurance. It is clear that strict clear guidelines and protocols are needed to ensure the validity and reliability of performance testing across the country. Quality assurance has many advantages, including the exchange of data between different diagnostic centres. These findings provide suggestions for critical review and improvement of testing practices.

DISTINCT HYPERTROPHY OF THE ELBOW FLEXORS AFTER INCLINE VERSUS PREACHER DUMBBELL CURL TRAINING

KOBAYASHI, Y., MAEO, S.1, EIHARA, Y.1, ONO, M.1, SATO, M.1, SUGIYAMA, T.1, KANEHISA, H.2, ISAKA, T.1
1. RITSUMEIKAN UNIVERSITY 2. NATIONAL INSTITUTE OF FITNESS & SPORTS IN KANOYA, JAPAN

INTRODUCTION: The elbow flexors consist of the biceps brachii (BB), brachialis (BRC), and brachioradialis (BRR). Among them, BB is a biarticular muscle crossing not only the elbow but also the shoulder joint, and lengthened more in a shoulder-extended than shoulder-flexed position. Previous studies have found greater muscle hypertrophy after training at long than short muscle lengths (e.g. seated > prone leg curl for the hamstrings [Maeo et al., 2021] and standing > seated calf raise for the triceps surae [Kinoshita et al., 2023]). Based on these findings, this study examined the effects of incline (shoulder-extended, BB lengthened) versus preacher (shoulder-flexed, BB shortened) arm curl training on elbow flexor hypertrophy.

METHODS: Twenty-one untrained healthy young adults participated in this study. Using a dumbbell, they performed incline arm curls with one arm and preacher arm curls with the other arm (shoulder 50-deg extended and flexed, respectively) at 70% of one repetition maximum of the corresponding task. Each arm performed 5 sets of 10 repetitions per session (2 s for each of the concentric/eccentric phases), 2 sessions per week for 12 weeks. Before and after the intervention, T1-weighted axial 3-T MR images (field of view: 200 × 200 mm, slice thickness & gap: 2.5 mm) were obtained to assess muscle volume of BB, BRC, BRR, and the whole elbow flexors. In addition to muscle volume, anatomical cross-sectional area (ACSA) was calculated/interpolated at 10% intervals of muscle length (i.e. 10–90%, proximal–distal) for each muscle to examine whether regional hypertrophy occurred after each training.

RESULTS: Muscle volume significantly increased in all three muscles and the whole elbow flexors for both arms. The changes in whole elbow flexor volume did not significantly differ between the incline and preacher conditions (+16.5% vs +17.6%, P = 0.167, Cohen's d = 0.18). However, the changes in BB muscle volume were significantly greater for the incline than preacher condition (+18.0% vs +14.9%, P = 0.026, Cohen's d = 0.41), with significant between-condition differences in ACSA changes found in proximal muscle regions (at 20–40%, P = 0.015–0.045, d = 0.48–0.80). On the other hand, BRC

(+17.0% vs +21.0% P = 0.022, d = 0.52) and BRR (+10.0% vs +13.0%, P = 0.018, d = 0.49) had significantly greater muscle volume changes after the preacher condition. Significant between-condition differences in ACSA changes were found in distal muscle regions (at 70–80%, P = 0.005–0.014, d = 0.76–0.81) for BRC and in a middle muscle region (at 60% P = 0.001, d = 0.72) for BRR.

CONCLUSION: While incline and preacher arm curls resulted in similar whole elbow flexor hypertrophy, the former appears more effective for BB and the latter for BRC/BRR hypertrophy, especially their proximal and distal/middle regions, respectively.

THE ROLE OF INTRACORTICAL INHIBITION FOR MOTOR MEMORY CONSOLIDATION

EGGER, S., WÄLCHLI, M., MEYER, S., TAUBE, W.

UNIVERSITY OF FRIBOURG

INTRODUCTION: Recent findings have demonstrated that low-frequency repetitive magnetic stimulations (rTMS) over the primary motor cortex (M1) impaired short-term consolidation of a balance task, underscoring the causal connection between M1 and the consolidation of balancing skills (Egger et al., 2023). However, the underlying neural mechanisms induced by rTMS and whether these adaptations endure over an extended period, encompassing multiple acquisition sessions, remain insufficiently elucidated. So far, its is widely acknowledged that GABAergic processes play an important role for consolidation (Sanes & Donoghue, 2000), at the same time, balance learning can enhance GABA-mediated inhibition (Taube et al., 2020). Therefore, the present study aimed to investigate the impact of rTMS on GABA-mediated short-interval intracortical inhibition (SICI) and to explore the role of M1 in the long-term consolidation of a balance task (i.e., across multiple acquisition sessions).

METHODS: Thirty-one volunteers underwent six balance acquisition sessions on a rocker-board, each followed by either rTMS or sham rTMS based on group affiliation. During the first and last training session, SICI was measured twice; before the balance acquisition and after the application of rTMS or sham-rTMS to investigate potential short- and long-term adaptations in intracortical inhibition. Adaptations were assessed during the execution of the learned balance task and in a non-learning postural control task (i.e., stable upright stance).

RESULTS: Regardless of group affiliation, all participants achieved comparable improvements within the balance acquisition sessions. However, consolidation varied between groups. In particular, between the third and the fourth acquisition session, as Tukey corrected post-hoc tests showed a significant decline in performance for the rTMS group (p = 0.006). Both short- (p = 0.014) and long-term (p = 0.038) adaptations in SICI were affected by rTMS: while the sham rTMS group upregulated SICI, rTMS led to reduced levels of inhibition. No neurophysiological effects were observed in the non-learning control task (upright stance).

CONCLUSION: The task-specific interference effect of rTMS on balance consolidation and on upregulation of SICI indicates that increased intracortical inhibition is an important mechanism to protect and consolidate newly acquired motor memories.

THE NEUROPHYSIOLOGICAL MECHANISMS BEHIND THE RELATIONSHIP BETWEEN TORQUE COMPLEXITY AND CONTRACTION INTENSITY: THE ROLE OF MOTOR UNIT BEHAVIOUR

OLIVEIRA, J., GOMES, J.S., BAUER, P., PEZARAT-CORREIA, P., VAZ, J.R.

FACULLTY OF HUMAN KINETICS

INTRODUCTION: Torque complexity has been proposed as a key marker of the ability of the neuromuscular system to adapt to external changes and, therefore, is considered as an important measure of motor control. Interestingly, the literature demonstrates an inverted U-shape relationship between the torque complexity and contraction intensity, suggesting that motor control is influenced by the intensity of contraction. Furthermore, it has been suggested that changes in torque complexity are only observed above the critical torque (CT)/end-test torque (ETT) intensity. However, the physiological mechanisms behind this well documented relationship are yet to be determined. This study aimed to investigate whether changes in motor unit behaviour (motor unit recruitment and firing rate) with contraction intensity would accompany and potentially explain the inverted U-shape relationship between force complexity and contraction intensity.

METHODS: 25 participants were asked to perform a knee extensors' sustained submaximal hold isometric task at the intensities corresponding to their ETT, 50%ETT, 75%ETT, 150%ETT and 175%ETT. Measurements involved recordings of sub-

maximal isometric torque while recording high-density surface EMG signals from the vastus lateralis (VL) and vastus medialis (VM) muscles. Sample Entropy (SampEn) and Coefficient of Variation (CV) were extracted from torque signals as measures of temporal structure (i.e. complexity) and magnitude of torque variability. EMG signals were decomposed into individual Motor Unit Action Potentials (MUAP) and Firing Rate (FR). A one-way ANOVA for repeated measures was performed on SampEn, CV, MUAP and FR to test the effect of contraction intensity on the temporal structure and magnitude of torque variability as well as on motor unit related measures. In addition, a stepwise multiple linear regression analysis was conducted to predict changes in torque SampEn based on changes in motor unit related variables.

RESULTS: The results showed an effect of contraction intensity on SampEn ($p<0.001$), with ETT and 150%ETT presenting higher SampEn's values when compared with 50%ETT ($p<0.001$) and 75%ETT ($p<0.001$ and $p=0.019$, respectively). For motor unit behaviour, we observed a significant effect of contraction intensity in MUAP and FR for both VL and VM (all $p<0.001$). The results demonstrated that MUAP and FR increased with contraction intensity until 175%ETT. Additionally, the multiple linear regression was statistically significant ($R2=0.18$, $p<0.001$), indicating that SampEn is lower when MUAP and FR of VL present higher and lower values, respectively.

CONCLUSION: The study demonstrated that torque complexity is contraction intensity dependent in an inverted U-shape relationship that could be, potentially, explained by changes in motor unit behaviour with contraction intensity, particularly above the CT/ETT, which could influence the capacity of the neuromuscular system to be flexible and to adapt the motor output to the changes in task demands.

ACUTE EFFECTS OF TRANSCRANIAL DIRECT CURRENT STIMULATION ON MAXIMUM STRENGTH PERFORMANCE AND ENDURANCE STRENGTH TASK IN HEALTHY YOUNG INDIVIDUALS.

GONZÁLEZ, I.M., COLOMER-POVEDA, D., SÁNCHEZ-MOLINA, J.A., MARCOS-FRUTOS, D., BOTANA-LÓPEZ, L., MORENILLA-BURLÓ, L., BOUZA-MÉNDEZ, K., MÁRQUEZ, G., LÓPEZ-ALONSO, V.

UNIVERSITY OF A CORUÑA

INTRODUCTION: Transcranial direct current stimulation (tDCS) is a safe, non-invasive, pain-less type of stimulation that has been used with the aim to influence different aspects of gross motor performance. The main objective of this study was to verify the acute effect of a single session of tDCS applied to the primary motor cortex (M1) or the dorsolateral prefrontal cortex (DLPFC), on maximum strength, endurance, neurophysiological and perceptual parameters, in a manual hand-grip task in healthy young adults.

METHODS: The study follows a randomized, controlled, triple-blind, crossover design with a placebo condition. The sample comprised 42 healthy university students (21.52±1.40 years; 19 women). Maximal strength, corticospinal excitability and intracortical inhibition and facilitation were assessed before and after the application of 20 minutes of 2mA tDCS (M1, DLPFC or Sham). After tDCS, the number of maximum contractions performed until a 30% loss of hand-grip maximum strength was recorded.

RESULTS: No effect was detected on maximal strength, corticospinal excitability, intracortical inhibition and facilitation, the number of repetitions done until a 30% of maximum strength loss and perception of effort following the administration of tDCS over M1 and DLPFC.

CONCLUSION: The results of the present study suggest that tDCS over M1 or DLPFC does not influence corticospinal and intracortical structures and has no effect over maximum strength nor the ability to repeat maximum contractions. The absence of corticospinal and intracortical changes precludes to link the response pattern between functional and neurophysiological variables. Further research is needed to determine under what conditions or tasks tDCS could potentially benefit gross motor performance before its recommendation as a tool aimed at optimizing performance during motor tasks.

DOES THE INITIATION OF A COGNITIVE TASK CAUSE A TEMPORARY DOWNREGULATION OF VESTIBULAR CONTROL OF BALANCE?

MALONE, Q., TUTT, H., REEKIE, P.K., DAKIN, C.J., MCNEIL, C.J., DALTON, B.H.

UNIVERSITY OF BRITISH COLUMBIA: OKANAGAN

INTRODUCTION: Vestibular control of balance is temporarily downregulated upon initiation of a goal-directed movement (e.g., reaching, gait, and posture transition), which fits with the optimal feedback control theory. This theory states that a sensation that does not contribute to, or causes interference with, a planned movement is downregulated (i.e., not used to plan the movement). With the previously examined tasks, it was not possible to isolate the effects of cognitive planning and transitions from the motor response with the previously examined tasks. As such, this experiment was designed to determine if a predominantly cognitive task also causes this vestibular downregulation. We hypothesised that initiation of a cognitive task response would cause a downregulation of vestibular control of balance.

METHODS: While standing on a force plate measuring ground reaction forces (GRFs), participants (N=18) received binaural, bipolar stochastic (0-25Hz, root mean squared≈1mA) electrical vestibular stimulation (EVS). Meanwhile, participants performed two tasks: 1) a simple reaction time (SRT) task requiring a button-press in response to a visual cue, and 2) a Stroop task requiring a verbal response to the textual colour of a presented word. These tasks were chosen because both involve a minimal motor response, yet require varying levels of cognitive complexity; a factor which influences many motor outcomes. Mean coherence between the EVS signal and the mediolateral GRF signal from 0-10Hz was calculated in 5ms

steps over 5000ms centered around the time of movement onset. Two-tailed, paired-sample t-tests were used to compare mean coherence 1000-600ms before movement onset and from 200ms before to 200ms after movement onset.

RESULTS: Contrary to our hypothesis, there was a significant increase in coherence upon initiation of the SRT task response ($t17=2.95$, $p=0.01$) and no differences for the Stroop task ($t17 = 1.92$, $p=0.07$).

CONCLUSION: These results imply that previously reported drops in vestibular control of balance are likely due to the transition to a gross movement, rather than a result of cognitive processes occurring during a transition. Potential explanations for the vestibular downregulation during a transition to a gross movement include: 1) a technical artifact arising from the data analysis technique used, or 2) a result of changes in head movement variability (which is positively associated with EVS-GRF coherence). That is, initiation of a gross movement causes anticipatory postural adjustments that stabilize the body and reduce head movement variability, which could downregulate the vestibular control of balance (lower EVS-GRF coherence). In contrast, during the transition to fine movements, there is no voluntary command to drive the head in a particular direction, so the balance controller remains reliant on vestibular cues to maintain posture.

CORTICOSPINAL EXCITABILITY IS NOT FACILITATED BY OBSERVATION OF ASYMMETRIC WALKING ON A SPLIT-BELT TREADMILL IN HUMANS

KITAMURA, M., ISHIKURA, T., OGISO, G., KAMIBAYASHI, K.

DOSHISHA UNIVERSITY

INTRODUCTION: Observing others actions facilitates the corticospinal excitability (CSE) of the muscles associated with the observed actions [1]. A previous study [2] indicated that motor-related brain areas are strongly activated when observers observe movements that they have repeatedly practiced and are already skilled in, compared to when they observe movements they have not experienced. The previous study only investigated voluntary movements with complex actions (e.g., dancing) and did not analyze semi-automatic rhythmic movements (e.g., walking). Thus, it is unclear how the observers motor system is activated by observing unusual walking patterns that they have not experienced before. Therefore, we aimed to investigate changes in CSE by observing walking in a split-belt condition with different left and right treadmill belt speeds, which the observers had not experienced before. When humans are exposed to the split-belt condition, their gait becomes asymmetric at the initial period of the split-belt condition but approaches symmetry after several minutes [3]. Thus, we examined CSE during the observation of the asymmetric and symmetric walking at the initial and late periods of the split-belt condition, respectively.

METHODS: Fifteen healthy adults participated in the study. From the video of lower limb movements during walking captured from the actors left side, three different video clips were created: 10 seconds during walking in the tied condition (belt speeds: 1.25 m/s), as well as the initial 10 seconds (initial period) and last 10 seconds (late period) during a 10-minute walking in the split-belt condition (left and right belt speeds: 1.0 and 1.5 m/s, respectively). The video clips showed that the actors step lengths were almost symmetric in the tied condition and late period of the split-belt condition, but largely asymmetric in the initial period of the split-belt condition. The participants observed a fixation cross (control condition) and three different video clips that were presented randomly on a monitor. The motor-evoked potential (MEP) of the left tibialis anterior muscle was recorded by delivering transcranial magnetic stimulation to the right primary motor cortex during the observation.

RESULTS: The MEP amplitude during the observation of walking in the tied condition and the late period of the split-belt condition was significantly larger than that in the control condition. However, no significant difference in the MEP amplitude was observed between the control condition and the initial period of the split-belt condition.

CONCLUSION: These results suggest that when observing semi-automatic movements like walking, observation of symmetric walking, similar to observers walking, facilitates CSE. However, observation of asymmetric walking, which observers have not experienced, does not appear to facilitate CSE.

EXAMINING VISUOMOTOR INTEGRATION BEHAVIOURS USING A SPORT-SPECIFIC TASK: DOES MOVEMENT SPEED (WALKING VS. RUNNING) AFFECT HOW ATHLETES AVOID COLLISIONS?

WALTERS, M., CINELLI, M.

WILFRID LAURIER UNIVERSITY

INTRODUCTION: In dynamic sports environments, athletes navigate complex scenarios, requiring split attention toward demanding tasks and interactions with opponents. Sport-specific training can improve one's ability to integrate visual information, potentially improving collision avoidance behaviour (1). However, athletes collision avoidance behaviours are task-specific, emphasizing the importance of challenging athletes in sport-like environments to elicit visuomotor integration enhancements (2). While previous research found no difference in collision avoidance behaviours between athletes and a general population when walking (3), the current study introduces running to evoke a sport-specific context. The aim of the study is to identify differences in collision avoidance behaviours of athletes between walking and running scenarios, with the hypothesis that athletes will exhibit superior performance in a sport-specific setting (i.e., when running).

METHODS: Sixteen field-sport athletes were immersed in a virtual environment using a Vive Pro 2 head-mounted display (HMD), while performing a collision avoidance task in a virtual soccer stadium. Participants were required to approach a goal, while avoiding a collision with a virtual player (VP) approaching at three different speeds. Athletes performed two blocks of trials (walking and running) in a counterbalanced order. Within each block, a secondary attention task was included in half of the trials to ensure sport-specificity; athletes reported a changing shape while simultaneously attending to the collision course. The HMD was used to record positional data to calculate each athlete's minimum clearance distance (m).

RESULTS: Although there were no differences in secondary task performance during running and walking conditions, results indicate a significant effect of movement speed on minimum clearance distance, $F(1, 15) = 10.19$, $p < .05$. As such, athletes maintained a small and constant minimum clearance distance between themselves and the VP when running, regardless of the VP's approach speed. Alternatively, when walking, the minimum clearance distance matched the speed at which the VP approached (i.e., greater distance when VP moving slower).

CONCLUSION: A consistently smaller minimum clearance distance in a sport-specific context suggests athletes are attuned to the limits of their action capabilities when challenged in a sport-like environment. Similar to research findings with aperture crossing (2), athletes can efficiently regulate their minimum spatial requirement while running. These insights are crucial for sports training and injury prevention, offering valuable knowledge on how athletes adapt to dynamic scenarios. Understanding these behaviours can inform training interventions aimed at enhancing athletes collision avoidance skills, ultimately fostering safer and more effective athletic performance.

DO ATHLETES HAVE BETTER DECISION-MAKING CAPABILITIES IN SPORT-SPECIFIC SITUATIONS

MYSKO, P., CINELLI, M.

WILFRID LAURIER UNIVERSITY

INTRODUCTION: Assessing the passability of a closing gap requires correct perception of affordances and the utilization of tau-coupling. Affordances are influenced by embodiment, which suggests that through experiences in different situations, a person will have a sense of self and can make accurate decisions based on their perceived abilities. Athletes who are presented with a task that matches their sports requirements show an increase in the accuracy of their behaviours, suggesting embodiment can be influenced by specific situations [1]. However, does embodiment impact the decision-making capabilities of athletes? Therefore, the studys purpose was to determine if athletes have better decision-making capabilities in dynamic sport-specific situations. We expected that athletes' actions would be better tuned when performing a task at a faster rate (i.e., closer to training situations).

METHODS: 6 field varsity athletes (4 male; 20.8±1.2yrs) were immersed in a virtual environment using a VR head-mounted display (HTC Vive Pro2). Individuals walked towards sliding doors situated 6.5 meters from start, at 3 meters from the aperture the doors began to close at a rate of 0.6-1.2m/s* each participant's baseline walking or running (approach) speed. Participants completed a total of 42 trials (i.e., 3 trials x 7 closing speeds x 2 approach speeds). Participants were instructed to approach the doors at a consistent speed only passing through the closing gap if they could safely cross without manipulating their body. Data analysis included distance from the aperture in which each participant slowed down for each closing rate and approach speed.

RESULTS: A significant interaction was observed between door closing rate and approach speed concerning slow down distance ($p = .002$). Post-hoc pairwise t-test between the door closing rate and approach speed showed a significant difference between walking and running at a closing rate of 1.0 ($p= .011$, $g= 0.49$). The switch point in behaviours (i.e, crossing doors vs. stopping prior to the doors) occurred at similar relative door closing rates for both approach speeds.

CONCLUSION: Findings suggest that athletes' actions are equally tuned when approaching closing doors while walking or running. Athletes' decisions (slow down distance) was similar during both approach speeds for each door closing rate. However, when the door closing rate was the most difficult (i.e., 1.0x), slow down distance was closer to the doors when running than when walking. The most probable explanation is that when the closing rate matched the athletes' boundary of success, they take more time for successful visuomotor processing to occur, leading to athletes getting closer to the doors when running.

PREDICTIVE VISUAL STRATEGIES IN HIGH-SKILLED TABLE TENNIS PLAYERS DURING FOREHAND RALLIES

SHINKAI, R., ANDO, S., NONAKA, Y., KIZUKA, T., ONO, S.

UNIVERSITY OF TSUKUBA

INTRODUCTION: Eye movements are crucial for acquiring visual information during interceptive performances such as table tennis. Previous studies have indicated that table tennis players spend less time looking at the ball as it approaches

them (Ripoll and Flurence, 1988; Rodrigues et al., 2002; Shinkai et al., 2022). However, it is still uncertain where table tennis players direct their gaze after tracking the ball. We hypothesized high skill players in table tennis would direct their gaze toward opposite side of the court because aiming the landing position of the ball they hit back is important based on kinematic information of the opposite player. In addition to gaze direction, attentional direction could enhance our understandings about visual strategies during rallies. Saccade eye movements reflect our attentions relative to visual targets (Hoffman and 77 Subramaniam, 1995). Therefore, we raised an additional hypothesis that the directions of saccades are also the opposite side of the court. Thus, the purpose of this study was to clarify the predictive visual strategies in skilled table tennis players during forehand rallies.

METHODS: Collegiate male table tennis players (n = 7) wearing an eye-tracking device (Pupil Invisible glasses, Pupil Labs, Berlin) conducted forehand rallies at a constant tempo (100, 120 and 150 bpm) using a metronome. In each tempo condition, participants performed a total of 30 strokes (three conditions). Gaze fixation time, areas of interest where gaze could be directed (Gaze target) and saccade eye movements were detected by video footage of an eye tracking device.

RESULTS: The mean relative fixation time on the ball approaching participants in each tempo condition was 19.6 ± 2.4 % in the 100 bpm, 19.5 ± 1.5 % in the 120 bpm and 19.4 ± 1.1 % in the 150 bpm. These data indicate that participants gazed at the ball approaching them only 20 % of the time during the rallies. After fixation on the ball approaching participants, most of gaze targets stayed on the opposite court in each tempo condition (100 bpm; 99 % of the total trials, 120 bpm; 100 % of total trials, 150 bpm; 97.7 % of total trials). Furthermore, gaze targets immediately after saccade eye movements tended to be other areas of interest away from the ball location. Thus, not only gaze targets but also the attentional directions were opposite side of the court.

CONCLUSION: We found that participants gazed at a ball approaching them only 20 % of the time during the rally. Participants tended to gaze at the ball when the opponent hit the ball and move their gaze away from the ball after that. Furthermore, saccades were directed toward the opposite side of the court including the opponent after tracking the ball. These findings suggest that focusing on the opponent's motion is important for successful forehand table tennis rallies. Taken together, skilled table tennis players are likely to use unique visual strategies for interceptive sports players to estimate spatiotemporal information about the ball.

THE EFFECT OF A SHORT TERM DYNAVISION-D2 TRAINING PROGRAM ON IMPROVING THE ACCURACY OF THE DYNAMIC THREE-POINT SHOOT

ABU ALIM, M., HATAMLEH, M.

YARMOUK UNIVERSITY

INTRODUCTION: Modern training seeks quick, effective training strategies to improve players skills. Sports vision training proved to enhance the efficiency and reaction time of the players performance by mainly enhancing the eye-brain coordination, perception, and visual processing of an athletes vision. The current study investigated the impact of a suggested training program using the Dynavision-D2 in improving the three-point shooting accuracy of the Yarmouk University basketball team.

METHODS: Eight players the coach recommended were selected out of 15 team members, who took part in two weeks (3 sessions (30 minutes each)/week) Dynavision-D2 suggested a training program alongside their regular team practice schedule, but on different weekdays. The Dynavision-D2 suggested intervention took place during the general conditioning training session of the university basketball training and had no focus on game skills training. The Dynavision-D2 training program was developed using pre-programmed training and assessment of the Dynavision-D2 software and a specific developed by researchers tests that included the T-scope, reaction time, Endurance, Proactive mode A, and the Reactive mode B, with a total training time of 30 minutes for each session. The accuracy of the dynamic three-point shoot was assessed using the widely used "60s dynamic three-point shooting" assessment (test protocol (Pojskić et al.,2014)). Statistical analysis included comparing the average scored points, percentages, and a paired T-test evaluation.

RESULTS: However, the suggested training programs effect was relatively small and non-statistically significant ($p>0.05$). The trained participants showed an improvement in their total scored points of the "60s dynamic three-point shooting" test; the average scored points on the pre-training were (6 points) and on the post-training were (8.6 points) as the average percentage accuracies improved from (15%) to (21.56%).

CONCLUSION: In practice, the results of including short-term Dynavision-D2 intervention could be helpful in detecting talented basketball shooters in early team preparation. In addition, it can assess coaches advance their efficient training program focusing on overall development. Furthermore, it could help players handle fatigue and stay accurate during the games. Further research studies are advised for further evaluation of implementing Dynavision-D2 interventions in early sports training stages.

PROTECTIVE EFFECT OF PHYSICAL ACTIVITY ON MORTALITY WITH EMOTIONAL DISTRESS IN KOREAN ADULTS

KIM, S.Y., CHOI, Y., KIM, Y.
SEOUL NATIONAL UNIVERSITY

INTRODUCTION: Emotional distress (ED) is known as a critical risk factor for mortality. The suicide rate in South Korea has been the highest among OECD nations, emphasizing the need for effective interventions to mitigate this risk associated with ED. Current physical activity (PA) guidelines recommend adults to engage in at least 150 min/wk of moderate to vigorous PA (MVPA) to prevent and manage health problems. However, the protective effect of PA against mortality in individuals with ED remains unclear. This study aims to investigate the impact of PA on mortality in individuals with ED.

METHODS: This study included 35,059 Korean adults from the 2007-2013 Korea National Health and Nutrition Examination Survey, with their all-cause and cardiovascular disease (CVD) mortality data linked up to 2019. ED was assessed using a self-reported questionnaire that evaluated the presence of stress, depressive symptoms (DS), and suicidal thoughts (ST). MVPA levels were also determined by questionnaires and classified as inactive (0 min/week), insufficiently active (<150 min/wk), and active (>=150 min/wk). Cox proportional hazards model was applied to estimate the risks of mortality associated with ED and MVPA levels. The study also assessed the combined effect of emotional status and MVPA on the risk of mortality. In a combined analysis investigating the association between ED and mortality risk across different levels of MVPA, six groups were categorized based on the presence of ED and MVPA levels (inactive, insufficiently active, active).

RESULTS: Over a mean follow-up of 9.2 years, 2,033 deaths occurred, including 439 from CVD. The hazard ratios (HR) for all-cause mortality due to stress, DS, and ST were 1.13 (95% CI: 1.02-1.26), 1.13 (1.00-1.27), and 1.34 (1.21-1.49), when compared to non-affected individuals. For those with all three ED categories, the HRs for all-cause and CVD mortality were 1.31 (1.10-1.55), and 1.72 (1.24-2.39). Adhering to PA guidelines was significantly associated with lower risk of mortality: 0.76 (0.62-0.94) for stress, 0.71 (0.55-0.92) for DS, and 0.76 (0.62-0.95) for ST. Similarly, CVD mortality risks were reduced to 0.47 (0.29-0.77), 0.43 (0.23-0.79), and 0.65 (0.41-1.02) for stress, DS, and ST, respectively. In the combined analysis, individuals with ED who engage in PA (either insufficiently active (HR =0.75 (0.57-0.98) or active (HR=0.79 (0.67-0.93)) were associated with a lower risk of all-cause mortality compared to those without ED but who were inactive (HR=0.83 (0.74-0.93)). Similar patterns of associations were observed for CVD mortality.

CONCLUSION: ED and MVPA were both independent predictors for risk of mortality. The higher risk of mortality associated with ED was significantly reduced by adherence to PA guidelines. Combined analysis also indicated that PA is associated with a lower mortality risk in individuals with ED, emphasizing the importance of promoting PA as a key strategy for reducing mortality risk in public health.

LOAD-VELOCITY PROFILING TO ESTIMATE ONE-REPETITION MAXIMUM IN OLDER MEN

DEBOUTTE, J., ALCAZAR, J., WALKER, S., DELECLUSE, C., VAN ROIE, E.
KU LEUVEN

INTRODUCTION: Resistance exercise is the primary therapeutic strategy to counteract age-related declines in muscle function. To individualize exercise intensity, training loads are often prescribed based on an individual's one-repetition maximum (1-RM) [1]. Despite the excellent reliability of 1-RM measurements [2], the protocol is time-consuming and may enhance the risk of injuries, especially in older adults [3]. Consequently, various approaches for estimating 1-RM, and thus accurate training intensity, have been introduced. The load-velocity (L-v) profile has emerged as one potential method, considering that movement velocity can accurately predict relative load [4]. Therefore, the aim of this analysis was to determine how accurately the 1-RM of older men can be estimated from their individual L-v profile.

METHODS: Sixty-four men (66.9 ± 5.4 years old) completed the L-v profiling protocol on a pneumatic leg press device [5]. The protocol started with a maximal isometric test, followed by explosive concentric leg extensions at five pre-fixed increasing loads. Each load was a set percentage of the maximal isometric force, and participants performed 2 to 3 attempts per load. For each of the five loads, the attempt with the highest mean velocity was selected, and the load and velocity values of that attempt were used to create each participant's individualized linear regression equation. Following the five sub-maximal contractions, all participants performed additional single repetitions until reaching 1-RM. Each individual's velocity at 1-RM was recorded and used to calculate the group's mean velocity at 1-RM. This value (0.10 ± 0.07 m/s) was used as an input in the individualized L-v equations to finally obtain each individual's estimated 1-RM.

RESULTS: Estimated 1-RM was slightly higher than measured 1-RM, but the difference was not significant (-0.5 ± 6.4 kg, p=0.525). In addition, the methods showed excellent absolute agreement (ICC=0.92, p<0.001). Despite the strong relationship at a group level, there was substantial inter-individual variability in the agreement between the two methods. The large difference between the estimated and measured 1-RM in some individuals was reflected in the Bland-Altman plot, as well as in the linear regression analysis that yielded a standard error of estimate of 6.3 kg.

CONCLUSION: Estimating 1-RM from L-v profiling provides a low risk, time-efficient alternative for prescribing resistance training load. The results are promising at a group level but may not be generalizable to all individuals and should therefore be interpreted with caution.

A DELPHI SURVEY OF THE KNOWLEDGE AND SKILLS OF A CLINICAL EXERCISE PHYSIOLOGIST IN THE UNITED KINGDOM.

OSIN, C., SADLER, I., CROZIER, C., GRAVES, L., DAWSON, E., MILLER, G., NAYLOR, L., GREEN, D., ASKEW, C., JONES, H.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Registered Clinical Exercise Physiologists (CEPs) are recognised healthcare professionals in the United Kingdom (UK) and are registered through the Academy of Healthcare Science (AHCS). Their practice is guided by the Clinical Exercise Physiology UK (CEP-UK) standards outlined in the scope of practice [1] and the accompanying curriculum framework [2]. This study aimed to identify and reach consensus on the key knowledge and skills of a UK CEP.

METHODS: Two phases, (i) a scoping review, (ii) a modified, 1-round Delphi survey were utilised. Key requirements were identified from analysis of 24 studies in the scoping review, and the current UK CEP standards and training documents. The survey contained CEP knowledge and skills (n=58), health conditions that a CEP should be able to work with (n=15), and healthcare professions that a CEP should understand the roles and expertise of (n=9). Academics (n=26), healthcare professionals (n=25), CEPs (n=10), service managers (n=6), and researchers (n=4) were identified through purposive sampling (university websites, and databases of exercise rehabilitation services), public advertisement through social media, and snowball sampling. A 1-to-5 rating Likert scale was completed by participants based on the importance of each component for a CEP to practice effectively in the UK.

RESULTS: n=58 of the 71 participants identified (82%) completed the survey. All knowledge and skills identified from the scoping review and the CEP-UK and AHCS standards and training documents (n=58) were accepted, with those in clinical practice (99.7%) deemed the most important and those in behaviour change and communication (82.7%) the least important. n=12 of the 15 health conditions identified (80%) were accepted, with cardiovascular and respiratory diseases (100%) being the most important and eating disorders (54%) the least important. All healthcare professions (n=9) were accepted, with specialist exercise instructors (100%) being the most important and podiatrists (73%) the least important.

CONCLUSION: The final consensus list contains 58 key knowledge and skills, 12 health conditions and 9 healthcare professions that are important for CEPs to work effectively in UK healthcare. This list shows that the current CEP-UK curriculum framework is fit for purpose. Further, this could contribute to future iterations of the framework, and form the bedrock of a growing workforce in the UK.

JOINT ASSOCIATIONS OF HYPERTENSION AND MEETING BOTH AEROBIC AND MUSCLE STRENGTHENING RECOMMENDATIONS WITH MORTALITY

HWAN, C.Y., YUNMIN, H., HOYONG, S., JIYEON, Y., DUCK-CHUL, L., YEON SOO, K.

SEOUL NATIONAL UNIVERSITY

INTRODUCTION: Hypertension is a well-known risk factor for various cardiovascular diseases (CVD), leading to premature deaths globally. Lifestyle interventions, such as physical activity (PA), can effectively mitigate the risk. While current PA guidelines recommend both aerobic PA and muscle-strengthening activities (MSA), most studies have focused mainly on aerobic PA, leading to uncertainty about the additional health benefits of MSA recommendations for individuals with hypertension. Therefore, this study aims to investigate the mortality risk associated with hypertension and adherence to both PA guidelines.

METHODS: This study included 34,990 participants from the 2007-2013 Korea National Health and Nutrition Examination Surveys (KNHANES), linked to Cause of Death Statistics through 2019. Participants were categorized into four groups based on current PA guidelines: Neither (aerobic PA < 500 METs-min/wk and MSA < 2 days/wk), Only MSA (aerobic PA < 500 METs-min/wk and MSA >= 2 days/wk), Only aerobic PA (aerobic PA >= 500 METs-min/wk and MSA < 2 days/wk), and Both (aerobic PA >= 500 METs-min/wk and MSA >= 2 days/wk). Cox regression, adjusting for potential confounders, estimated hazard ratios (HR) and 95% confidence intervals (CI) for associations of hypertension and meeting PA guidelines

with all-cause and CVD mortality. Stratified analyses assessed whether the relationship between meeting PA guidelines and mortality varied based on hypertension status. Additionally, participants were cross-classified into eight groups to assess the joint association of hypertension status and meeting PA guidelines with mortality, with the reference group being hypertensive participants meeting neither of PA guidelines.

RESULTS: During 9.2 years of the mean follow-up period, 1,948 participants died from any cause, and 419 from CVD. Hypertension was associated with a higher risk of mortality (HR 1.11, 95% CI, 1.01-1.22 for all-cause; HR 1.40, 95% CI, 1.14-1.73 for CVD) compared to normotensive participants. However, adherence to both aerobic PA and MSA guidelines was associated with a lower risk of mortality (HR 0.72, 95% CI, 0.61-0.85 for all-cause; HR 0.54, 95% CI, 0.36-0.80 for CVD). This association was more pronounced in hypertensive participants, but not apparent in normotensive participants. Joint analysis showed that hypertensive participants meeting both aerobic PA and MSA guidelines consistently had lower mortality risk compared to normotensive participants meeting neither of guidelines. Overall, adherence to both PA guidelines was associated with lower risks of all-cause and CVD mortality, regardless of hypertension status.

CONCLUSION: The findings of this study indicate that meeting both aerobic PA and MSA guidelines, as recommended by current guidelines, is associated with a significant reduction in the risk of all-cause and CVD mortality, even among hypertensive individuals. These results underscore the importance of not only aerobic PA, but also MSA as public health strategies.

ASSOCIATIONS OF SEDENTARY TIME AND PHYSICAL ACTIVITY WITH MORTALITY A REPROSPECTIVE FROM THE KOREA NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY (KNHANES)

YUN, S., YOUNGHWAN, C., YEON SOO, K.
SEOUNL NATIONAL UNIVERSITY

INTRODUCTION: Sedentary time (ST) has been recognized as an independent health risk factor, regardless of moderate-to-vigorous physical activity (MVPA). Although the relationship between sedentary time and a higher risk of mortality has been found in earlier research, only a few studies have examined the combined effects of ST and MVPA on mortality risk. Thus, the purpose of this study was to investigate the association of ST and MVPA with all-cause mortality.

METHODS: We analyzed data from 8,568 Korean adults who participated in the 2014-2015 Korea National Health and Nutrition Examination Survey (KNHANES). During follow-up through 2019, a total of 172 deaths were documented. Cox proportional hazard model was used to examine the associations of ST and MVPA on mortality. To determine the risk of mortality associated with ST and MVPA, ST was categorized into 6 groups (<4, 4-6, 6-8, 8-10, 10-12, >=12 hr/day) and MVPA was categorized into 3 groups (0, 1-149, >=150 min/wk of MVPA). In combined analysis, participants were categorized into 6 groups based on their level of SB (<8, 8-12, >=12 hr/day) and MVPA (<150, >=150min/wk). Reference group was defined as SB <8 hr/day and MVPA >=150min/ wk.

RESULTS: The longest ST (>=12 hr/day) was associated with a significantly increased risk of mortality (HR = 2.10, 95% CI 1.20-3.67). Conversely, increasing levels of physical activity were associated with a decreased risk of mortality (HR = 0.64, 95% CI 0.43-0.94 for insufficient activity; HR = 0.58, 95% CI 0.40-0.82 for active group). When examining the combined effects of ST and MVPA on mortality , we observed a progressive increase in mortality risk with higher sedentary group, particularly among those with insufficient activity (HR = 1.90 95% CI 1.18-3.05 for 8-12 hr/day; HR = 2.63, 95% CI 1.61-4.27 for >=12 hr/day). However, individuals who were sufficiently active (>=150 min/wk of MVPA) were not associated with a higher risk of mortality, regardless of their ST.

CONCLUSION: Our findings suggest that adhering to current physical activity guidelines (>=150min/wk of MVPA) may attenuate the higher risk of mortality associated with high sedentary time. These results highlight the importance of incorporating sufficient MVPA to counteract the detrimental effects of prolonged ST.

This study was funded by the Shenzhen Research Fund [JCYJ-20230807-14041-4029].

THE EFFECT OF EIGHT WEEKS OF VIGOROUS EXERCISE TRAINING ON IRON STATUS IN YOUNG MEN AND ITS ASSOCIATION TO PHYSICAL PERFORMANCE

ALTMAN, A., MARKUS, I., GEPNER, Y.
TEL AVIV UNIVERSITY

INTRODUCTION: Iron deficiency (ID) is prevalent among extensively trained recreational and professional athletes. Unaddressed, ID may accelerate degradation in both physical and cognitive performance. This study aimed to determine the effect of eight weeks of high-volume exercise training on hepcidin and ferritin concentration, and its association to physical performance, cognitive functions, and agility.

METHODS: Thirty healthy males (18-30y, 75.5±5.9kg) were recruited from a base training combat unit to participate in eight weeks of high-volume (30 h/week) exercise training with a monitored diet. Iron status, inflammation, and endocrine markers were measured pre- and post-intervention. In addition, anaerobic capacity (peak and mean power), muscle strength [isometric mid-thigh pull (IMTP), hand grip (HG), and vertical jump (VJ)], and reaction agility were measured. Changes between baseline and post-eight weeks were assessed by paired sample t test.

RESULTS: Significant (p<0.001) increases were found in hepcidin (51.2 ± 41.7%) and ferritin (50.8 ± 60.6%) following eight weeks of training compared to baseline. In addition, significant (P<0.001) elevation was found in cognitive function [agility tests (-14.2 ± 9%), cognitive stressor tests (-3.7 ± 5.7%)] and muscle strength [IMTP (12.1 ± 9.1%), HG (8.8±12%), and VJ

(5.6±11%)]. IL-6 increased (31±1.9%, p = 0.059) following the training and was strongly associated with hepcidin change (r=0.448, P<0.01), but not with ferritin (p=0.34). Changes in iron status were not associated with changes in exercise performance. Although no associations were found between total calories or macronutrient intake and iron status, total protein intake during the training correlated with ferritin change (r=0.376, P<0.05).

CONCLUSION: Eight weeks of high-volume exercise training among young active male increase hepcidin and ferritin. Those changes were not associated with exercise performance, but with chronic inflammation.

BELT ELECTRODE ELECTRICAL STIMULATION PREVENTS DENERVATION-INDUCED MUSCLE ATROPHY IN MULTIPLE SKELETAL MUSCLE GROUPS IN RATS.

UNO, H., KAMIYA, S., AKIMOTO, R., HOSOKI, K., TADANO, S., ISEMURA, M., KOUZAKI, K., TAMURA, Y., KOTANI, T., NAKAZATO, K.

NIPPON SPORT SCIENCE UNIVERSITY, HOMER ION LABORATORY CO., LTD.

INTRODUCTION: Electrical muscle stimulation (EMS) induces muscle hypertrophy and inhibits atrophy. EMS is thought that pad electrodes are most often used in clinical practice. However, it is difficult to activate multiple muscle groups simultaneously and efficiently as in voluntary exercise, because the electrodes are usually placed on the target muscle and current can only be applied to a single muscle, making it difficult to exercise multiple muscle groups simultaneously and obtain the effect of suppressing muscle atrophy. Recently, a method called Belt Electrode Skeletal Muscle Electrical Stimulation (B-SES) has been considered to be effective in addressing the problems of pad electrodes. This is an electrical stimulation method that can stimulate multiple muscle groups simultaneously. In addition to being able to stimulate multiple muscle groups simultaneously, the electrode area is larger than that of a pad electrode, resulting in a smaller amount of current per unit area (current density) and an increase in the maximum threshold value that can be tolerated when energized, thus enabling more intense stimulation. Although the clinical usefulness of B-SES has been demonstrated, its molecular mechanism remains unclear. In this study, we developed a novel rodent B-SES ankle stimulation system to test whether tetanus stimulation prevents muscle atrophy caused by denervation and examined the effect of B-SES on preventing muscle atrophy.

METHODS: Ten-week-old male SD rats were divided into an untreated control group (CONT), denervation group (DEN), and denervation and electrical stimulation group (DEN+ES). DEN+ES rats wore belt electrodes on both ankles and were energized between the two electrodes. Electrical stimulation was applied once two days for 7 days under isoflurane inhalation anesthesia, beginning immediately after denervation, at a frequency (60 Hz) that induces tetanus in rats for 5 minutes (5s on 2s off cycle). Twenty-four hours after the last electrical stimulation, the rats were bled to death under anesthesia, and the tibialis anterior and gastrocnemius muscles were removed bilaterally.

RESULTS: After 7 days of denervation, muscle wet weight (n=8~11) and muscle fiber cross-sectional area (CSA, n=6) of tibialis anterior and gastrocnemius muscles were lower in DEN and DEN+ES than CONT showed atrophy but were significantly higher in DEN+ES than DEN, showing atrophy prevent. In 18s and 28S ribosomal RNA, DEN+ES was significantly higher than CONT and DEN in the tibialis anterior and gastrocnemius muscles.

In addition, mRNA levels of muscle proteolytic signals, Atrogin-1 and Murf1, were greatly increased by denervation compared to CONT, while B-SES suppressed their expression (p<0.05).

CONCLUSION: Tetanus stimulation of both rat ankles with belt electrodes may effectively prevent denervation-induced atrophy in multiple muscle groups by sciatic nerve transection via enhancement of muscle protein synthesis and prevention of muscle proteolysis.

A CROSS-SECTIONAL STUDY OF SEASONAL HIKING FREQUENCY, INJURIES AND FOOTWEAR CHOICES OF HIKERS.

JOCHER, K., JACOB, I., BREEN, S., SQUIBB, M., BLACKBURN, H., ODDY, C., FRANCIS, P.

SOUTH EAST TECHNOLOGICAL UNIVERSITY

INTRODUCTION: Hiking is a form of physical activity (PA) (Caspersen et al., 1985) that typically takes place in natural environments e.g. mountains/countryside/forests. The habitual performance of this type of PA is reported to have many health benefits (Manferdelli et al., 2019). Other than this, little is known of what defines a hiker, their injuries and behaviours. The aim of this study was to determine seasonal hiking participation, injuries sustained and footwear choices among hikers.

METHODS: A cross-sectional questionnaire design was used to determine seasonal hiking participation, injuries sustained and footwear choices among hikers. Participants were recruited from Ireland (n = 62), United Kingdom (n = 37), United States of America (n = 18) and New Zealand (n = 6) through hiking/hillwalking organisations/groups on social media, emails and word of mouth. Two-hundred-and-eight individuals responded, of which eighty-five individuals were excluded (78x drop-out/incomplete, 7x Chronic Illness/Advised not to participate in PA by medical professional), One hundred and twenty-three were included in the analysis (Biological Sex: n= 58 male, n = 63 female, n= 2 prefer not say, age = 45 ±14.6). The survey was designed using Qualtrics TM software (version 2023) and statistical analysis was conducted using IBM SPSS statistical software package version 28.1.0.

RESULTS: 69% (95% CI: 0.59, 0.79) of hikers participated in hiking during all 4 seasons. Spring, Summer and Autumn demonstrated the highest participation rates (93 – 98% of participants) and winter had the lowest participation rates (72%, 95% CI: 0.65, 0.79).

Injury incidence among hikers is 37% (95% CI: 0.28, 0.46) in the previous 12-months. The foot (30%, 95% CI: 0.16, 0.44), knee (26%, 95% CI: 0.13, 0.39) and ankle (23%, 95% CI: 0.10, 0.36) were the most injured anatomical sites in injured hikers. Traditional style shoes were most prevalent among hikers (81%, 95% CI: 0.74, 0.88), followed by minimalist shoes (11%, 95% CI: 0.05 – 0.17) and barefoot hikers (2%, 95% CI: 0.0, 0.06), 3% (95% CI: 0.0, 0.05) of hikers used a combination of traditional and minimalist shoes.

CONCLUSION: This study is the first to report data on seasonal hiking participations, injuries sustained and footwear choices from a sample of hikers located in Ireland, the United Kingdom, United States of America and New Zealand. This data may act as a positive first step in profiling hikers for future research in the areas of injury prevention and footwear choices.

HELICOPTER LOADMASTERS´ OCCUPATIONAL LOADING

OJANEN, T., KOIVURANTA, J., KYRÖLÄINEN, H., HONKANEN, T.

FINNISH DEFENCE RESEARCH AGENCY

INTRODUCTION: The workload of helicopter loadmasters can be physically and mentally demanding. The workload has been studied mostly with questionnaires instead of objective measures. The purpose of this study was to find out the amount of physical and mental load on the loadmasters before the flight (PRE), during the immediate flight activities (WALK), during the actual flight (FLIGHT), and after (POST/POST2) the flight.

METHODS: A total of 16 (age 34±6 yrs., height 180±5 cm, and body mass 82±5 kg) male loadmasters voluntarily participated in the study. Data on the occupational load of loadmasters was collected through objective and subjective measurements. As objective measurements, heart rate and heart rate variability, saliva biomarkers, and isometric and dynamic force production tests were used. The aim of the objective measurements was to obtain information on the functioning of the cardiovascular, autonomic nervous, and excretory systems at PRE, WALK, FLIGHT, and POST/POST2 time points. A diary was used as a subjective method, with which the loadmasters evaluated the load caused by the flight and the other activities on the day of the flight.

RESULTS: The maximum heart rate of the loadmasters during the flight was significantly higher compared to other measurement periods (FLIGHT = 173±14 bpm vs. PRE = 133±21 bpm, $p<0.01$, WALK = 153±16 bpm, $p<0.05$ & POST = 145±20 bpm, $p<0.05$), but heart rate variability was significantly lower during WALK than during POST (SDNN = 47±14 ms vs. 58±15 ms, $p<0.01$; RMSSD = 39±17 ms vs. 51±17 ms, $p<0.05$). Based on the cortisol levels, the load of the loadmasters was significantly higher PRE than POST or POST2 (PRE = 8.35±3.79 nmol/l vs. POST = 5.57±3 .79 nmol/l, $p<0.05$ & POST2 = 5.12±3.03 nmol/l, $p<0.05$). The saliva alpha-amylase concentration was significantly higher after POST compared to POST2 (150.23±99.94 U/ml vs. 87.62±69.18 U/ml, $p<0.01$). No statistically significant differences were observed in the results of the physical tests. Based on the subjective assessment collected from the subjects, the load caused by helicopter flights on a scale of 1–10 was a 6.

CONCLUSION: According to the present study, the physical load on loadmasters during the flight is momentarily intense but not long-lasting. In addition, standing still during the flight seems to enable the activation and recovery of the parasympathetic nervous system of loadmasters, further reducing the overall physical load caused by the flight. In addition, good muscle endurance and maximal strength may have a more significant effect than aerobic endurance in reducing the load of the flight tasks. In the future, it will be important to study more in detail the load exerted by different load-bearing components during a flight.

FROM COURT TO WELLNESS: A SYSTEMIC REVIEW OF THE BENEFITS OF HEALTH AND WELL-BEING OF BADMINTON FOR CHILDREN AND YOUNG PEOPLE

YIN, C., XIAOJIA, C., SHUJIE, L.

UNIVERSITY OF EDINBURGH

INTRODUCTION: Acknowledging the limited appeal of the current health system for adolescents, this study advocates for badminton, a globally embraced sport with over 220 million participants (Phomsoupha & Guillaume Laffaye, 2014), to promote health and well-being in individuals under 25.

METHODS: Following PRISMA 2020 guidelines, the study meticulously searched key databases from October to November 2023, identifying 29 studies exploring badmintons impact on health and well-being in young people. Screening, using WHO age range criteria, resulted in a robust selection, and ATLAS.ti software facilitated systematic categorization and analysis.

RESULTS: Conducting a comprehensive review of 937 papers, the study included 29 studies examining the relationship between badminton engagement and health and well-being in young people. The most productive year was 2022, with China as the predominant research location. The diverse focus of studies encompassed recreational, academic, and

professional badminton types, with a collective sample of 3746 participants. Interventions targeted physiological parameters, fitness levels, mental health, and cognitive function, yielding significant positive improvements.

CONCLUSION: Badminton emerges as a multifaceted catalyst for fostering the overall well-being of young individuals. Significant contributions to physical health include impacts on bone mass, muscular strength, flexibility, and cardiovascular fitness (Gustavsson et al., 2003; Tervo et al., 2010; Naughton and Carlson, 1991; Stovba et al., 2019; Mohammed, 2020; Lee et al., 2021). The sport also showcases substantial cognitive benefits, enhancing eye–hand coordination, cognitive functions, and neural efficiency (Dube et al., 2015; Jawoeski et al., 2017; Hung et al., 2018; HÜLSDÜNKER et al., 2017; Liao et al., 2017; Dai et al., 2016; Santos et al., 2022; Chen et al., 2019; Akin et al., 2017).

Badminton positively influences mental health, promoting emotional stability and reducing psychological stress, particularly crucial during the transitional phase of youth (Li, 2004; Li et al., 2010; Yue & Xiao, 2022; Zhang et al., 2016; Wu & Li, 2022; Pan & Song, 2022; Chen et al., 2021; Cabello-Manrique et al., 2022). The discussion highlights the sports potential as a lifelong engagement tool, promoting intrinsic motivation, sports commitment, and excellence desires (Gomis-Gomis et al., 2023; Chen et al., 2021). Inclusive interventions, like "Shuttle Time Badminton Lessons," emphasize adaptability and motivational impact, making it a promising avenue for fostering sustained physical activity and sports participation among diverse young populations. In essence, badminton emerges as a holistic tool positively impacting the physical, cognitive, and mental well-being of young individuals, contributing to lifelong engagement in sports and physical activity.

ASSOCIATION BETWEEN PHYSICAL FITNESS AND TRAINING COMPETENCE AMONG ADOLESCENTS

GROßE SIEMER, J., THIENES, G.

UNIVERSITY OF VECHTA

INTRODUCTION: Supporting people to adopt and maintain an active lifestyle is a worthwhile goal. Across Europe, around 27% of over 15-year-olds participate in self-organized sport without supervision. In addition to promoting motor fitness, this emphasizes the need to develop a training competence, that enables people to plan, carry out and evaluate their training activities independently according to their individual requirements and without the need for supervision. Training competence encompasses knowledge on effects, exercises and methods of training and the application of that knowledge as well as perceiving exertion and pacing training accordingly. Here we investigate the relationship between physical fitness (PF) and training competence (TC). This is based on the assumption that training competence is acquired during the training process.

METHODS: A cross-sectional study was conducted with adolescents in German schools from grades 5-12 (138m / 77f; M 16.05 SD 2.56 years) and bivariate Pearson correlation and (multiple) linear regression analysis were performed to analyze the relationship between PF (independent variable) and TC (dependent variable). PF was determined with different tests for strength, coordination, flexibility and aerobic endurance and values were standardized to ensure comparability. TC (five facets with three items each) was collected using a standardized questionnaire with five-point Likert scales [1].

RESULTS: The standardized total score for PF showed a moderate positive correlation with total TC ($n = 215$; $r = .318$; $p = <.001$). Significant correlations were found for all five facets ($r = .16$ - $.35$). Differences in the correlations between girls and boys are not significant; only slight differences were found between some classes for three facets. The regression, controlled for sex and age, explained 18% of the variance in total TC ($r2 = .18$, $f (3, 209) = 15.29$, $p <.001$) and showed a significant association with total TC for PF (beta = .28, $p <.001$). Significant associations were found for four of the five facets (beta = .11 - .30). Age was negatively associated with total TC (beta = -.26, $p <.001$).

CONCLUSION: As expected, higher PF in adolescents correlates positively with TC overall and PF is a predictor of TC. Future research should include the assessment of training experience as a suspected moderator between PF and TC [2] and beyond that help clarify the unexpected negative correlation between age and TC.

INVESTIGATION OF METHODS FOR IDENTIFYING THE OCCURRENCE OF ADOLESCENT AWKWARDNESS DURING THE GROWTH SPURT AND THE TIMING OF SUBSEQUENT RAPID DEVELOPMENT: A CASE STUDY

KOKUDO, S.

CHUKYO UNIVERSITY

INTRODUCTION: Beunen and Malina (1986) reported that 25% of boys exhibit a temporary decrease in running speed during the growth spurt period. Furthermore, Philippaerts et al. (2006) found that 30m dash speed decreased by -0.6 seconds/year 12 months before the age of peak height velocity (APHV) in junior soccer players. Kokudo (2019) indicated

that there may be a temporary stagnation in running speed development and a deterioration of running movement due to adolescent awkwardness (AK) just before or after the APHV. He also highlighted the difficulty in treating the occurrence of AK as a group phenomenon due to significant individual differences in the timing of rapid developmental stages and motor skills, underscoring the necessity of meticulously tracking individual changes.

The purpose of this study was to investigate methods for clarifying the appearance of AK and the characteristics of its subsequent development. Additionally, it aimed to elucidate the process of onset and offset of AK through a case study targeting individuals who have undergone continuous training and have long-term records of height and athletic performance.

METHODS: We hypothesized that the emergence of AK would be more likely in exercises that involve moving ones body weight, and that this feature would be more pronounced with ongoing training. The subject was a Japanese male who continuously performed the high jump from primary school until adulthood, with a final height of 180.5 cm and a best high jump record of 2.15m. Growth data were collected from school health checkup records. Due to the rarity of individuals recording all their performances, records equaling or surpassing previous personal bests and the ages at which these records were achieved were used as data. A modified BTT model, including two logistic functions with the infant growth period defined as constant, was used for growth data. For the high jump record, the BTT model, characterized by three logistic functions, was employed to analyze performance development (Bock et al., 1990).

RESULTS: The goodness of curve fitting was R^2 = 0.999 for growth and R^2 = 0.994 for high jump performance development, indicating excellent fits. The peak height velocity (PHV) was 10.66 cm/year at age 12.25 years. Performance development speed was less than 5.0 cm/year from ages 10.9 to 12.7 years. A rapid development speed was observed shortly thereafter, from 13.0 to 13.8 years of age, reaching 126.8 cm/year at 13.4 years of age, 1.15 years after APHV. At this time, the height velocity was 6.74 cm/year, which was 63.2% of the PHV. The growth rate remained above 7 cm/year until around 17 years of age.

CONCLUSION: The BTT model, with three combined logistic functions, adequately explained the growth in height and development of performance. In this sample, performance stagnation was observed during the period corresponding to the adolescent surge phase, but the end of the growth surge phase represented an explosive period of rapid developmental progression.

ADOLESCENTS WITH TYPE 1 DIABETES PERCEPTIONS OF 24-HOUR MOVEMENT BEHAVIOURS: A MIXED METHODS STUDY

PATIENCE, M., KIRK, A., JANSSEN, X., SANDERS, J., CRAWFORD, M.

UNIVERSITY OF STRATHCLYDE

INTRODUCTION: Adolescents with type 1 diabetes (T1D) are required to manage their condition throughout the entire 24-hour day. Physical activity, sedentary behaviour and sleep (24-hour movement behaviours) all play a crucial role in the management of T1D [1], yet no research has explored adolescents with T1Ds perceptions towards all three behaviours collectively. The aims of this study are to conduct a mixed method study to explore adolescents with T1D perceptions of 24-hour movement behaviours (24-h MBs) and assess the amount of time they engage in each behaviour.

METHODS: Qualitative data was gathered using semi-structured interviews. These were recorded, transcribed using intelligent verbatim and analysed using thematic analysis. Quantitative data was gathered using a wrist-worn accelerometery (GT3X-BT). The Hildebrand cut-points were used to categorise sedentary behaviour (SB), <35.6 mg/1s, light physical activity (LPA), ≥35.6 mg/1s and moderate-vigorous physical activity (MVPA), ≥201.5-706.9 mg/1s, while the Van Heest heuristic algorithm was used to estimate sleep.

RESULTS: In total 15 adolescents (6M, 9F) participated with mean age 14.6±2.0yrs, HbA1c 7.4±1.0%, diabetes duration 3.7±3.1yrs. Most used a continuous glucose monitor (80%) and delivered insulin by pump (67%). The main themes arising from the data were: 1) adolescents understanding of 24-h MBs (indicating awareness of how one behaviour impacts the other); 2) adolescents perception of 24-h MBs on mood (indicating better sleep and increased physical activity had a positive impact on mood, whereas sedentary behaviour had a negative impact) and 3) adolescents perceptions of 24-h MBs impact on blood glucose (mixed perceptions on their relation to blood glucose levels). Average sedentary time was 9.8±1.7h/d, LPA time was 5.6±1.4h/d, MVPA time was 28.5±27min/d and sleep time was 8.1± 0.7h/night. Most of the sample did not meet the MVPA recommendations (91.1%) while 58.3% met the sleep duration recommendations.

CONCLUSION: This study highlights adolescents with T1Ds understanding of the interconnectedness of each behaviour within a 24-hour day and the positive impact the correct balance of each behaviour can have on mood/emotions. Despite this, a large proportion of adolescents with T1D in this study are not meeting the 24-hour movement behaviour recommendations. The results from this study promote the use of a holistic 24-hour movement behaviour approach in the management of T1D and can inform future interventions aiming to support healthy 24-hour movement behaviours in this population.

EFFECTS OF STRENGTH TRAINING IN UPPER SECONDARY SCHOOL PHYSICAL EDUCATION CLASSES DEPENDING ON THE ENJOYMENT OF TRAINING

THIENES, G., GROßE SIEMER, J.
UNIVERSITY OF VECHTA

INTRODUCTION: The effectiveness of strength training has been proven for physical education (PE) classes. Few findings include the conditions of German schools or higher adolescence [1]. Pupils who actively participate in strength training can link it to the self-efficacy experience of being able to influence their own motor performance and change their fitness in a self-directed manner through their own effort and commitment to training. The assumption to be tested is then that the students expressed enjoyment of training opens up these positive experiences, which then indirectly contribute to the greater effects of the training. This study examines enjoyment of strength training as a possible relevant (indirect) influencing factor on the effectiveness of training.

METHODS: Of 88 adolescents (68m/20f; M 17.5 SD 1.30 years), 54 participated in the 7-week resistance training programme. Strength training took place once a week during physical education classes, and the average training compliance was 4-5 training sessions (training group). A whole-body strength circuit of 12 exercises was implemented in the 90 minute lessons in conjunction with conversations and reflective discussions in class. Lessons in the parallel classes were not related to strength training (control group). Curl-up, back test, pull-up hang and push-up [3] and sport enjoyment scales [2] were collected.

RESULTS: Mixed ANOVA shows a significant interaction effect in favour of the TG for the push-up ($F(1.0, 85.0) = 12.79$, $p < .001$, eta-sq = .13), the pull-up hang ($F(1.0, 86.0) = 8.18$, $p = .004$, eta-sq = .09), and the back test ($F(1.0, 86.0) = 13.93$, $p < .001$, eta-sq = .13). In addition, a significant interaction was found in favour of the group that enjoyed the training more for the push-up ($F(2.0, 50.0) = 4.65$, $p = .014$, eta-sq = .15) and the curl-up ($F(2.0, 51.0) = 3.67$, $p = .032$, eta-sq = .12).

CONCLUSION: Evidence is supported by three out of four tests, that under conditions of PE classes in Germany training once a week has low but relevant effectiveness [4]. The study also suggests that enjoyment of strength training leads to significantly greater training effects for two of the four test procedures, with medium to large effects. It is recommended to investigate potential age-related and methodological causes, such as the time of survey.

EFFECT OF A NATIONWIDE INITIATIVE (HEALTHY ACTIVE LEARNING) ON PHYSICAL ACTIVITY OF CHILDREN AGED 5-13 YEARS

ALI, A., MUGRIDGE, O., OBRIEN, W., BASU, A., MUMME, K., ADAMS, J., SNOWLING, N.
MASSEY UNIVERSITY

INTRODUCTION: The Healthy Active Learning (HAL) initiative aims to increase physical activity (PA) of students in school and community settings. This study examined the effect of HAL on PA metrics using accelerometry.

METHODS: Students (5-13 y) wore an accelerometer on the non-dominant wrist for 5-7 days. Data (hourly steps; sedentary, light, moderate and vigorous minutes/hour) were recorded at two timepoints (T1=2020/21, T2=2022/23) at 46 New Zealand schools. Schools were classified by the level of intervention at each timepoint. Phase 1 schools (P1) were baseline at T1, Phase 2 schools (P2) were baseline at T2. Logistic regression explored the effect of HAL over time for overall movement; in-school (9am-3pm); out-of-school (7-9am/3-9pm, weekdays); weekdays; and weekend movement.

RESULTS: Overall, 1972 students (~53% female, mean age 9.5y) participated from 17 Phase 1 schools (n=756 [T1], n 457 [T2]) and 19 Phase 2 schools (n=489 [T1], n=272 [T2]). Some students (n=134) took part at both timepoints. In-school steps increased over time for Phase 2 schools and decreased for Phase 1 schools (1213 [T1, P1] to 1178 [T2, P1] steps/hour, 1177 [T1, P2] to 1215 [T2, P2] steps/hour, p=0.001). Overall, in-school, and weekday light minutes/hour increased for Phase 1 and Phase 2 schools (20 [T1, P1] to 33 [T2, P1] minutes/hour, 20 [T1, P2] to 33 [T2, P2] minutes/hour, p=0.02; p<0.001, p=0.03 respectively). In-school and weekday moderate/vigorous minutes/hour decreased for Phase 1 and Phase 2 school (21 [T1, P1] to 14 [T2, P1] minutes/hour, 22 [T1, P2] to 15 [T2, P2] minutes/hour, p<0.001; p=0.02 respectively).

No effect of HAL over time was observed for overall, out-of-school, weekdays and weekend steps; any time measure of sedentary minutes/hour; out-of-school and weekend light minutes/hour; overall, out-of-school and weekend moderate/vigorous minutes/hour; nor longitudinal student data.

CONCLUSION: The increase in light intensity activity over sedentary behaviour is a positive outcome. Nevertheless, there was a significant reduction in MVPA in both Phase 1 and Phase 2 over time. This may be due to low-intensity PA during the so-called 'brain breaks' that was becoming more commonplace in schools. In-school activity was higher than out-of-school activity, and weekend hours. However, the changes to sedentary, light and MVPA were similar to overall activity.

CONTRIBUTION OF WALKING TO AND FROM SCHOOL ON OVERALL PHYSICAL ACTIVITY: A ONE-YEAR FOLLOW UP STUDY

SASAYAMA, K.

MIE UNIVERSITY

INTRODUCTION: Walking to and from school rates are low in many countries (Aubert et al., 2022). Therefore, the contribution of active transport to the overall population's MVPA is relatively low (Martin et al., 2016). In addition, Larouche's review (Larouche et al., 2014) on the relationship between active transport and physical activity highlighted a limited number of longitudinal studies. This study examines the prospectively relationship between walking to and from school and physical activity in a sample with a high rate of Japanese children who walked to and from school.

METHODS: A total of 76 participants (57.9 % girls) completed baseline and follow-up assessments. Their mean age was 9.6 ± 1.0 years at baseline and 10.6 ± 1.0 years at follow-up. The participants' mode of school commute was measured by a questionnaire. Step counts, sedentary time, light physical activity (LPA) and moderate-to-vigorous physical activity (MVPA) were assessed using an accelerometer (ActiGraph, LLC, Pensacola, FL, USA). Comparisons of physical activity variables at baseline and follow-up were analyzed using the Wilcoxon signed-rank test. The contribution of walking to and from school to the entire day was calculated. The tracking of physical activity was analyzed using Spearman's correlation coefficient.

RESULTS: Overall physical activity levels decreased at follow-up compared to baseline. However, the contribution of walking to and from school to overall physical activity significantly increased at follow-up compared to baseline, especially in step counts and MVPA. Walking to and from school contributed to the participants' overall physical activity in MVPA were 39.6 ± 15.3% and 49.1 ± 13.8% for all participants at baseline and follow-up, respectively. The tracking correlation coefficients were high for the steps counts ($r = 0.799–0.889$, $p < 0.05$) and MVPA ($r = 0.713–0.745$, $p < 0.05$) in before school and after school.

CONCLUSION: Walking to and from school significantly contributed to overall daily physical activity in primary school students. Physical activity during the school commute in short-term exhibited a low-to-strong association. In conclusions, these findings emphasize the importance of promoting physical activity interventions and implementing school policies that encourage walking to and from school.

CHILDREN'S PHYSICAL ACTIVITY BASED ON NUTRITIONAL STATUS

UVACSEK, M., WÁGNER, B.

HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

INTRODUCTION: Inactivity is the fourth most important risk factor for early death (WHO 2010). WHO's aim for 2030 is to decrease inactivity by 15% (WHO 2018). Monitoring the different types of activities in children is the first essential step in order to achieve the global goal. The aim of the study was to collect data about primary school children's physical activity. The questionnaire was compiled using the Global Matrix 4.0 indicators. We asked parents about the children's overall physical activity, organized sport and physical activity, active transport and activity doing together, and their parental support.

METHODS: In the online data collection, 677 parents (42.85±6.49 years old) provided information about 677 children (10.98±2.53 years old). Data were collected in spring 2023 using social media platforms and internet correspondence. The nutritional status categories were determined by WHO reference. Our questionnaire was edited with the Qualtrics program, and the data were analyzed using TIBCO 14.0 Statistics.

RESULTS: Altogether, 77% of children achieved the 60-minute MVPA/day on average; the highest rate was 81% in the underweight children group, and the lowest (63%) was found in overweight children. 63% of children participated in organized sport or activity; the highest rate (67%) was found in the normal weight group and the lowest (51%) in obese children. Active transport was present at the same level in every group. Interestingly, the overweight and obese children's rates (81%) were a bit higher than the others. Doing physical activity with parents was most characteristic in normal-weight children (73%) and the least in obese children (63%). The parental support for physical activity was also high, 83% in general, with the highest rate (88% in underweight children) and the lowest in the overweight group.

CONCLUSION: The physical activity of children changed in a positive direction compared to previously published data. Active transport was chosen at a higher rate than before, and the data for family support also increased. Based on nutritional status, the data was not significantly different, which means that overweight and obese children had almost the same participation rate in sports activities as others.

SCHOOL NEIGHBORHOOD PHYSICAL ENVIRONMENT, SOCIOECONOMIC STATUS, AND PHYSICAL ACTIVITY OF ADOLESCENTS IN JAPAN

OISHI, K., AOKI, T., MORI, T., IKEUE, K., YAMAGUCHI, H., HANANO, H., YAMAMOTO, Y., HIROE, Y., ISHII, K.
DOSHISHA UNIVERSITY

INTRODUCTION: Abundant physical activity in adolescents is not only consistently and favorably associated with various health indicators, but also transitions to an active lifestyle in adulthood. In recent years, an increasing number of studies have focused on the neighborhood physical environment as a potential factor related to physical activity. However, previous studies have been biased in favor of a few countries. Thus, this study aimed to clarify the association of school neighborhood physical environments and socioeconomic status (SES) with adolescents' physical activity.

METHODS: A total of 21491 fifth- through twelfth-grade students from 76 schools covering all regions of Japan were included in the study. The International Physical Activity Questionnaire for Japanese Early Adolescents was used to investigate daily time of vigorous physical activity (VPA) and moderate-to-vigorous physical activity (MVPA). Using the geographic information system, three natural environment elements, seven built environment elements, and areal deprivation index (ADI) as SES variables were examined in each school neighborhood.

RESULTS: For elementary school students, the amount of green cover was significantly positively associated with VPA for the low ADI group. For junior high school students, average temperature was significantly positively associated with VPA for the overall group, average temperature and the amount of green cover for the low ADI group, and the number of parks for the high ADI group. For high school students, average temperature and the number of sports facilities were significantly positively associated with VPA for the overall and low ADI groups. For elementary school students, average temperature was significantly positively associated with MVPA for the overall and high ADI groups. For junior high school students, average temperature was significantly positively associated with MVPA for the overall group, average temperature and the number of intersections for the low ADI group, and average temperature, the number of parks, and the number of destination types for the high ADI group. For high school students, ADI and the number of public transportations were significantly negatively associated with MVPA, while average temperature was significantly positively associated with MVPA. When dichotomized by ADI, average temperature and the number of sports facilities were significantly positively associated with MVPA for the low ADI group, and the number of intersections for the high ADI group.

CONCLUSION: A number of physical environmental factors were significantly associated with physical activity among adolescents, suggesting the presence of contextual effects. In particular, higher temperatures may promote physical activity among adolescents. The built environment factors associated with physical activity in adolescents differed by school type and socioeconomic status, suggesting the need for flexible built environment development based on developmental stage and local SES.

LONGITUDINAL STUDY OF THE DEVELOPMENT OF MOTOR IMAGERY IN PRIMARY SCHOOL CHILDREN: PRELIMINARY FINDINGS FROM A ONE-YEAR FOLLOW-UP STUDY

MALI, A., ŠLOSAR, L., PUŠ, K., MARUSIC, U.
SCIENCE AND RESEARCH CENTRE KOPER

INTRODUCTION: Motor imagery (MI) involves mentally stimulating actions without physical movement and can be kinaesthetic (KI) or visual, where one can either imagine the sensation of the movement in the body or imagine the image of movement from internal (IVI) or external (EVI) perspective. Throughout various development phases, children acquire and refine a multitude of skills. However, the process by which MI develops with age and the factors that play the most significant role in its progression remain unclear. Research on the combination of MI and motor skills has predominantly targeted the adult population, and more studies need to explore the impact of regular physical activity on MI and its developmental trajectory during childhood. This study aims to compare the results of MI after one year and recognise any changes in the development of MI in primary school children.

METHODS: The Movement Imagery Questionnaire for children (MIQ-C) was used to measure the MI ability of forty-four children (twenty-one boys and twenty-three girls) between the ages of 7 and 13 years. The MIQ-C was performed twice, with assessments conducted a year apart. The results were compared between the two assessment days, and gender and athletic status differences (athletes N = 24; non-athletes N = 19) were evaluated. Correlations between MI ability and age were also determined.

RESULTS: Correlation testing between age and MI perspectives revealed significant associations with IVI and EVI at both Day 1 (IVI rs = 0.476, P = 0.001; EVI rs = 0.600, P = 0.000) and Day 365 (IVI rs = 0.453, P = 0.002; EVI rs = 0.479, P = 0.002). Notably, KI showed no correlation with age across both assessment periods (Day 1: rs = 0.271, P = 0.075; Day 365: rs = 0.253, P = 0.102). Mann – Whitney U test showed there were differences in KI between athletes and non-athletes on both Day 1 (KI p = 0.023) and Day 365 (KI p = 0.012), and no difference in IVI and EVI (p > 0.05).

CONCLUSION: The preliminary results of this longitudinal study show no difference in MI between the two assessments. It highlights that on both assessment days, there was a significant association between age and IVI and EVI, suggesting that the development of MI is related to age-related changes in internal and external perspectives. The KI is better developed in children involved in sports, indicating the potential impact of physical activity on MI development. This study provides valuable insights that influence the development of MI in primary school children and highlights the need for further research in this area.

THE FOOTWEAR HABITS AND PREFERENCES OF AUTISTIC CHILDREN AND ADOLESCENTS

KUCZYNSKA, A., JONES, A., FRANCIS, P., KINSELLA, S.
SOUTH EAST TECHNOLOGICAL UNIVERSITY

INTRODUCTION: Autistic children often receive a Sensory Processing Disorder (SPD) diagnosis, marked by atypical sensory responsiveness (Brout & Miller, 2015). This can present in clothing intolerance, yet little research explores the impact of footwear on sensory-related issues in this population (Daly et al., 2022; Kyriacou et al., 2023). This study aimed to examine the relationship between sex, autism support levels, SPD diagnosis, and footwear choices. A secondary aim of this study was to explore parental perception of changes in a childs motor skills and behaviour when wearing shoes.

METHODS: Data obtained for this study came from a more extensive mixed-methods questionnaire on the experiences of autistic children and their parents in relation to footwear. The questionnaire was administered to autism families with a version for parents of autistic children (4-18 years) and a modified version for autistic adolescents aged 13-18. Only one questionnaire could be answered within the household. Both questionnaires were created using the Qualtrics platform. Participants were sampled from the UK and Ireland between October 2022 and April 2023 and recruited through autism charities, organisations, schools, support groups, and social media. Analysis used descriptive statistics, chi-square tests, Mann-Whitney U, Kruskal-Wallis tests, and thematic analysis. Statistical Package for Social Sciences (SPSS), version 28, and Excel software were used to analyse the results.

RESULTS: A total of 314 responses were received, with 82% completed by parents and 18% by adolescents. Most children (77%) were 4-12 years old, with 69.1% males and 28.9% females. Support levels were: 52.5% Level 1, 26.4% Level 2, and 21.1% Level 3. Additionally, 50% of children received a formal SPD diagnosis. Footwear choices included lace-less trainers (31%), Velcro shoes (20%), and laced trainers (20%). No significant associations were found between footwear choices, support levels, sex, or SPD categories ($p>0.05$). However, 90.5% of children could not/would not tie shoelaces, with females displaying higher lacing proficiency ($\chi2(2, n=300) =7.95$, $p<0.05$, Cramers V = 0.16). Preferences favoured light, loose-fitting, soft, and smooth shoes for sensory comfort. Forty per cent of respondents noted changes in a childs motor skills, behaviour, and emotional status when wearing shoes, with the majority describing negative changes.

CONCLUSION: This study found no significant differences in footwear choices based on sex, support levels, or SPD diagnosis, but preferences for specific shoe types were evident. Differences in motor skills, behaviour, and emotional status, when children wore shoes, were noted, emphasising the potential shoe intolerance in autistic children. This study further highlights the importance of ongoing research into footwear for this population to optimise motor skills, behaviour, and emotional health.

SPRINT RUNNING DEVELOPMENT: EXAMINING 100 METERS PERFORMANCE BETWEEN SPANISH AND FRENCH ATHLETES FROM JUNIOR TO SENIOR CATEGORIES.

AGUDO-ORTEGA, A., SALINERO, J.J., RODRIGUEZ-BARBERO, S., VALERO, F., GONZALEZ-RAVE, J.M.
CASTILLA-LA MANCHA UNIVERSITY

INTRODUCTION: Human development is a messy, complex, and difficult road to predict. At an early age, growth, maturation, and development occur simultaneously and influence physical activity, fitness, and performance (1), however, in the sports domain, the development of athletes will be strongly determined by favourable environments (2). To date, no study has analysed the differences in terms of sprint performance across categories between countries. The objective of our study is to compare the progression of marks from junior (U16 and U20) to senior categories between two different European countries.

METHODS: An observational and longitudinal analysis was carried out using the Spanish Athletics and French Athletics Federations database rankings. We analysed the top 25 marks from 100 meters sprint running athletes (1523 recorded marks; 757 females and 766 males) from U16, U20 and senior categories who have been recorded between 2015 and 2019. A two-way ANOVA (country x category) was used to analyse the differences between Spanish and French sprint athletes' marks. Effect sizes (ES) were calculated by using the Cohen's d (<0.20 trivial, ≥0.20-0.59 small, ≥0.60-1.19 moderate, ≥1.20-1.99 large, and ≥2.00 very large) (8).

RESULTS: The two-way ANOVA illustrated significant interaction ($p < 0.01$) between countries and categories. There were significant differences between countries both in males and females in U16 ($p = 0.017$ in females and $p < 0.01$ in males), in U20 ($p < 0.01$ in females and males) and the senior category ($p < 0.01$ in females and males). However, this difference increased from a small effect size at U16 (0.30 females; 0.58 for males) to moderate at U18 (0.82 for females and 1.08 males), and large at the senior stage (1.55 females, 1.49 males).

CONCLUSION: Data between Spanish and French sprint running athletes show significant differences between all categories from U16 onwards. Although the results showed significant differences in all categories, the effect size increases as athletes progress through the categories widening the gap between countries. These results reinforce the idea that national sports systems might play an important role in long-term athletes' development.

AWARENESS SURVEY ON VIDEO ANALYSIS IN JAPANESE MENS WRESTLING

TAKATANI, S.

UNIVERSITY OF TSUKUBA

INTRODUCTION: In recent years, the filming of practices and competitions in many Olympic sports has become commonplace, being utilized for the analysis of athletes techniques and characteristics. It has also become an indispensable tool for athletes and coaches in analyzing rival players techniques, match dynamics, and constructing tactics.

While video analysis is considered a valuable factor in enhancing athletes performance, there have been no initiatives in Japanese wrestling to capitalize on these benefits, and prior research on the utilization of video analysis in competitions or related areas is not evident. The purpose of this study is to gather input from active athletes, coaches, and the wrestling association in Japan to elucidate their impressions, perceived necessity, expectations, and barriers preventing the implementation of video analysis in wrestling.

METHODS: This study conducted a single 70-minute group focus interview with a total of eight participants, including three athletes with experience in international competitions, three coaches with experience in coaching international development athletes, and two members of the associations strengthening committee. Participants were selected using the purposive sampling method, and prior to the survey, the researchs purpose, objectives, and details regarding recording were explained. Informed consent was obtained before proceeding.

The semi-structured interview consisted of three main questions:

Impression of video analysis

Barriers to video analysis

Expectations for video analysis

Analysis Method: The recorded interview data were transcribed verbatim, and qualitative analysis was conducted using the KJ method to identify and categorize key themes and insights.

RESULTS: In a survey on video analysis, various opinions were gathered from athletes, coaches, and the association. Despite the absence of prior strategies utilizing video analysis in the sport, all participants expressed the necessity of video analysis in wrestling. However, there is a concern in Japan regarding the prohibition of recording match footage, and even during practice, filming is restricted without the consent of training partners.

CONCLUSION: In the sport of wrestling, the challenge has been the lack of analysis and implementation of acquired footage, hindering its application in the field. This study aimed to elucidate the awareness, barriers, and expectations regarding video analysis from the perspectives of athletes, coaches, and the wrestling association. As a result, it is believed that the findings can contribute as a stepping stone to enhance the international competitiveness of wrestling in the future.

ADDITIVE EFFECTS OF EXPERT MODELING AND VIDEO ANALYSIS ON TECHNIQUE DEVELOPMENT IN NOVICE SPORT CLIMBERS

DEBEVEC, T., LESKOŠEK, B., OKRŠLAR, L., VRECEK, L., BLAGUS, R.

JOZEF STEFAN INSTITUTE

INTRODUCTION: Sport climbing is becoming increasingly popular around the world, and this is reflected in its inclusion in the 2020 Tokyo Olympics program and further approval for the 2024 Paris and 2028 Los Angeles Olympic games. It is a complex sport that, besides physical underpinnings, also requires appropriate techniques to master and optimise movements. However, training methodologies aimed to facilitate climbing technique acquisition are still in their infancy. Given the previously suggested potential of expert modeling and video analysis to facilitate climbing technique learning we aimed to investigate their utility for the development and acquisition of three climbing-specific techniques (drop knee, heel hook, and high step).

METHODS: Thirty novice climbers completed two testing sessions before and after a climbing intervention consisting of three supervised training sessions. During the training sessions, participants climbed symmetrical boulder problems designed to target the three techniques. Participants were randomly assigned to a control group, who received verbal feedback, or an experimental group that additionally received expert modeling and video feedback via the Dartfish tablet application. Expert video model was recorded using the same female expert climber (bouldering world cup finalist) exe-

cuting each move of the problem with 100% accuracy and fluency. Video recordings of all participants" movement executions were subsequently evaluated by two climbing experts on a 7-point scale.

RESULTS: There were no significant differences between the two groups in terms of age, gender, body mass, height, ape index, and past climbing experience. Also, the expert scores did not differ significantly between the control and experimental group during pre-testing for all techniques. The intervention increased the expert scores significantly in both groups ($p<0.001$), but more so in the experimental than in the control group for the high step ($p=0.017$). Improvements for the drop knee ($p=0.52$) and heel hook ($p=0.75$) were similar in both groups.

CONCLUSION: These data suggest that a coached climbing session(s), that is performed correctly and under the supervision of an experienced climbing coach, can quickly lead to substantial technical improvements in novice climbers. When compared to coached session solely, the use of video analysis and expert video modeling has the potential to additionally enhance the acquisition of certain climbing skills, particularly those related to movement efficiency/technique.

EFFECTS OF SHORT DURATION INTERVENTION ON SWIMMING PERFORMANCE, ON MIDDLE ADOLESCENCE SWIMMERS.

NICOLAOU, K., LOUCAIDES, G.
CYPRUS SPORTS ORGANIZATION

INTRODUCTION: In improving swimming performance, training volume (VOL) increases, or short high intensity speed efforts, or both in the right mixture apply in the regime of athletes (2,3). A previous study involving elite adult swimmers suggested that with an increase of training VOL, that had a polarized method (POL), small improvements in 100m performance was produced. Studies with elite adults show slightly improved performance that is not highly consistent to all (1). Critical velocity (CV) is the swimming speed an athlete can hold for a long time without significant exhaustion and drop in speed (5). The incremental speed intensity spectrum demonstrates that heart rate (HR) and LA show a positive linear correlation (4). The aim of this study was to observe how 6 weeks intervention (increase in training VOL with: small segment of those km in high intensity, and a big segment of km in low and middle intensity training), using individual training speeds, affected performance in adolescent swimmers.

METHODS: Middle adolescence swimmers, N=7 (5 females, and 2 males avg.16.1 y old +1.1years, avg b.w. 59.6kg +6.8kg), underwent an incremental step test, 6x100m, departing every three-min and reaching their true max effort at the 6th repetition. Warm-ups varied between 500-700m. Two evaluations occurred, T1 and T2, six weeks apart. In T1 & T2, it was recorded: body mass (kg), (heart rate (bpm), and LA m.mol during each step), LA, post max effort, to calculate removal rates. Active recovery took place post max effort. All recorded info were analyzed and presented on a graph with X and Y axis of LA m.mol & V m/sec respectively. After T1, training indices had an increased km load (compared before T1), between 11-18%. Training VOL was broken down for simplification in three intensities z1 & z2 (A1), z3 & z4 (A2), and z5 (A3). The km in the intervention phase were broken down in terms of intensities as: A1= 45%, A2=46%, and A3=+6%. .

RESULTS: After T2 these results emerge. An increase in lactate tolerance, or LAMAX in 6 out of 7 swimmers (86%), with 1.9, sd +2.7 m.mol. A smaller increase, 4 out of 7 swimmers (57%) produced faster times, with 1.2 sec, sd+ 3.6sec. In T2, 1 out of 7 swimmers (14%) was able to lower LAMAX values and remove lactic acid (LA) post max effort, 4 out of 7 (57%) maintained a similar removal rates, and 2 out of 7 (29%) revealed a lower removal ability.

CONCLUSION: The individual training zones from the LA & V curve, during T1, were used. The removal rates of LA post max effort did not reveal great results, probably due to further aerobic work that is needed for that mechanism. Obstacles can materialize during the training process, and each swimmer has different coping mechanisms brought forward for adaptation. In conclusion this intervention, showed a promising improvement for some adolescent swimmers in swim performance, and more in LA tolerance. 1. M J Costa et al 2013 2,3. IN IT TO WIN IT?:TRAINING HABITS OF MALE AND FEMALE ENDURANCE RUNNERS.

DEAR, S., PUMMELL, E.K.L.1, AUGUSTUS, S.1, SWANN, N.2, MOIR, H.J.1
1 KINGSTON UNIVERSITY <2 UNIVERSITY OF SURREY>

INTRODUCTION: Representation of female runners in mass participation events is growing (1) although when it comes to performance, male athletes still appear to dominate (2). Studies have highlighted certain sex differences in relation to physiological qualities such as VO2max and fat metabolism (3) yet there is limited understanding of the training habits, perspectives, and event participation of male and female runners. The aim of this study was to determine how male and female runners train, where they seek training information and their approach to race participation in terms of performance outcomes and key event attractors.

METHODS: An online survey was cascaded to experienced runners (5km, <25minutes) between January 2022 and April 2022. The survey was comprised of 39 questions, and there were 335 responses analysed (163 females, 172 males). Participants reported competing over distances from 5km to ultramarathons (>42.4km). Data were analysed through descriptive statistics; Pearson Chi-square tests were performed to identify differences between the sexes and Mann-Whitney U tests were used to examine differences in training volumes/frequency of runners following a programme and those who were not.

RESULTS: Both weekly running volume and running frequency were broadly similar for both groups ($p>0.05$) although males were more likely to complete >50km a week (56% males, 39% females) and run 5 times or more a week (55%

males, 47% females). More male runners believed they had adequate time available to exercise (66% males, 52% females), work commitments were stated as the biggest barrier to participation for both sexes. Most runners obtained their training information from online sources, with 59% following a training plan. Running frequency, volume and injury rate were similar between those following a programme and those working independently. Speed was stated as the key performance marker runners wanted to improve. It was reported that guidance was lacking in respect to the female hormonal cycle and how this affects training. In relation to race participation, 162 runners enrolled in 1-5 events a year, only 25% of females and 30% of males enrolled in more than 10 events a year. Scenery and cost proved key attractors to event selection, for female runners' enjoyment was the main performance objective, for men it was race time.

CONCLUSION: Although no significant difference was detected in the training habits adopted by male and female runners it appears men invest more time in the sport and perceive fewer participation barriers, indicating scope to further reduce the performance gap between the sexes. Those hosting running events should be aware of what runners' value and the outcomes that are important when attracting particular demographics. The study also highlights more accessible research relating to the menstrual cycle and menopause is required to support female participation.

VARIABLES ASSOCIATED WITH MARATHON PACING OUTCOME: A SCOPING REVIEW

SLATER, M., WILLMOTT, A., GORDON, D.

ANGLIA RUSKIN UNIVERSITY

INTRODUCTION: Even pacing is integral to achieving optimal marathon performance and the fastest time, with runners who maintain close-to-even splits considered to possess superior pacing ability [1]. However, research on factors associated with marathon pacing outcome has not been consolidated. This scoping review aimed to (a) identify marathon pacing indices present in the literature, (b) succinctly summarize and disseminate research findings on variables associated with marathon pacing, (c) determine which variables may exhibit the strongest relationships with marathon pacing, and (d) identify any significant gaps in the literature to guide future research. Understanding these aspects is crucial for enhancing both theoretical knowledge and practical applications in marathon pacing.

METHODS: A systematic search of SPORTDiscus, Web of Science, SCOPUS, and PUBMED identified relevant studies. Eligibility criteria followed the Joanna Briggs Institute framework, including participants >18 years old, comparing variables with calculated marathon pacing metrics from road races.

RESULTS: Searches identified 2119 studies; 42 full-texts were analysed, with 20 studies meeting inclusion criteria. These studies unveiled five pacing metric categories: absolute average change in speed, early vs. late segment analysis, pace range, 5 km coefficient of variation, and second vs. first half slowing. Sixteen categories of variable were identified: age, sex, marathon time, gender, previous marathon races, training, marathon time prediction, psychological constructs, physiological measures, muscle breakdown biomarkers, race ranking, halfway time, shorter race personal bests, performance level, environmental conditions, anthropometrics, and carbohydrate consumption. Challenges arose in comparing results due to diverse metrics and analytical methods. Nevertheless, carbohydrate consumption, overall marathon time, performance level, and environmental temperature emerged as factors with the strongest relationships to pacing outcomes.

CONCLUSION: The literature exhibits bias toward demographic data, neglecting psychological, physiological, nutritional, and strategic factors related to the skill of marathon pacing. Moreover, minimal research focuses on practical applications to aid marathon runners in improving their pacing outcomes. This bias impedes the researchs practical relevance for runners aiming to enhance the skill of pacing. Further exploration into these underrepresented areas is warranted, and future studies should prioritize these aspects, opting for research designs beyond cross-sectional analytical studies whenever possible.

PHYSICAL FITNESS, PSYCHOLOGICAL CHARACTERISTICS AND GAME PERFORMANCE IN YOUTH MALE SOCCER PLAYERS

GIANNAKI, C., KOUDELLIS, M., TSOULOUPAS, C., APHAMIS, G., CHRISTOU, M., BOGDANIS, G.

UNIVERSITY OF NICOSIA

INTRODUCTION: Soccer is a sport with various demands, including good levels of physical fitness, technical and tactical qualities, while the psychological demands are also high (1,2). In recent years, the development of match analysis systems has allowed the examination of factors associated with game performance, including tactical parameters (3). The current study aimed to examine the associations between physical fitness, psychological parameters, and game performance in young soccer players.

METHODS: Two-hundred forty-three young male soccer players (aged 16-17 years) participated in this study. A number of physical fitness parameters were assessed, including cardiorespiratory fitness, countermovement jumping (CMJ) ability, sprinting, and change of direction (COD). Body fat was estimated using skinfolds measurement. Psychological characteristics were evaluated using the Profile of Mood State (POMS) questionnaire, Athletic Coping Skills Inventory (ACSI-28) and the Test of Performance Strategies (TOPS). Technical and tactical data were recorded and assessed during a competitive

soccer match using a multicamera, semiautomatic optical tracking system. The InStat index was considered an index of game performance. A multivariate linear regression model was used to evaluate the predictors of game performance.

RESULTS: Game performance was associated with coping with the adversity and coachability subscales of ACSI-28, tension-anxiety, anger-hostility and fatigue-inertia sub-scales of POMS. Of the physical fitness parameters examined, only COD and CMJ with free arms were associated with game performance, while a tendency toward significance was found regarding cardiorespiratory fitness.

CONCLUSION: Both physical and psychological parameters are essential predictors of game performance. Both specific physical fitness and psychological parameters in youth soccer players should receive special attention as this appears to affect game performance.

ASSOCIATION BETWEEN ISOMETRIC MIDTHIGH PULL FORCE-TIME CHARACTERISTICS AND RUNNING ECONOMY AT HIGH RUNNING SPEED IN WELL-TRAINED DISTANCE RUNNERS

TANJI, F., NISHIDE, N., MOROZUMI, H., MIYAZAKI, S.

TOKAI UNIVERSITY

INTRODUCTION: Ground contact time during running is less than 250 ms and becomes shorter as speed increases. Distance runners must produce force to support body weight from their lower limb muscles in this short ground contact time. The short contraction time may not allow for maximal muscle force. However, the ability to produce faster and higher lower limb muscle force would contribute to increased running gait stability and less energy expenditure (i.e., increased running economy [RE]) at a given running speed. The use of isometric mid-thigh pull (IMTP) can be used to measure the lower limb's maximum force-generating capability (peak force), the rate at which force is developed (rate of force development [RFD]) and force produced at various time points (force epoch) (Lum et al., 2020). Therefore, we aimed to clarify the relationship between force-time characteristics obtained from IMTP and running economy (RE) at low and high running speeds.

METHODS: Twenty-five well-trained male distance runners (age, 19 ± 1 years; height: 172.6 ± 4.5 cm, body mass: 57.3 ± 3.6 kg), with a mean seasonal best time of 14:07.8 ± 0:54.7 for 5,000 m run, participated in this study. They performed a multi-intermittent incremental running test on a treadmill. RE was calculated using oxygen uptake, respiratory exchange ratio and accumulated blood lactate concentration (Tanji et al., 2017) at 250 and 330 m/min running (their blood lactate concentration was 1.8 ± 0.3 and 5.3 ± 1.3 mmol/L, respectively). In addition, they performed an IMTP test on an instrumented force platform with an IMTP testing rack. The highest absolute peak force and RFD at 0–100 (RFD0–100) and 0–200 ms (RFD0–200) from the onset of pull were used for analysis. Pearson's correlation coefficient was analyzed to determine the association between IMTP measures and RE, and the significance was set at a P value of < 0.05.

RESULTS: The absolute peak force, RFD0–100 and RFD0–200 were 1722 ± 255 N, 5405 ± 1788 N/s and 4124 ± 919 N/s, respectively. There was no significant relationship between RE at 250 m/min (0.98 ± 0.06 kcal/kg/km) and each IMTP measure ($r = -0.14$, -0.09 and -0.13, respectively; $P > 0.05$). RE at 330 m/min (1.09 ± 0.08 kcal/kg/km) had a significant relationship with the RFD0–200 ($r = -0.46$; $P < 0.05$) and no significant relationship with the absolute peak force and RFD0–100 ($r = -0.31$ and -0.28, respectively; $P > 0.05$).

CONCLUSION: These results suggest that the ability to produce high force up to 200 ms in lower limb strength contributes to superior RE at high running speed. It can be concluded that well-trained distance runners must train their lower limb muscle strength and run-based training.

FACTORS THAT INFLUENCE ACTUAL PLAYING TIME: EVIDENCE ON CHINESE FOOTBALL ASSOCIATION SUPER LEAGUE

ZHANG, G., WANG, J., LI, S., CAO, J.

TONGJI UNIVERSITY

INTRODUCTION: The actual playing time of football is a crucial index for assessing the excitement and caliber of a league. With advancements in data tracking technology in football matches, the statistical analysis of net duration has progressively become more efficient and convenient. A study has conducted to explore factors influencing actual playing time of Chinese Football Association Super League (CSL).

METHODS: 40 factors were classified into quantifiable(n=9) and non-quantifiable (primary = players, team, character of a game, referee, and others, secondary =26) indicators. Entropy method was used to ascertain the weights of quantifiable indicator. The magnitude of dispersion is positively correlated with the impact of the indicator on the comprehensive evaluation. The data encompasses from 240 matches involving 16 teams in the CSL during season 2018. For non-quantifiable indicators, 40 experts specializing in football were invited to evaluate these indicators through a structured questionnaire.

Following the principal component analysis method was to derive the weights for each indicator. The weights of primary indicators are composed by aggregating the secondary indicators.

RESULTS: For quantifiable indicators, the highest weights of indicator were the opponents free kicks in their own half (0.1760), followed by the restart of play after scoring a goal (0.1738), and throw-ins (0.1302). For non-quantifiable indicators, the weight of player was 0.1920, which influenced by the top three secondary indicators being subjective procrastination intent (0.0447), aggressiveness (0.0432), and physical fitness (0.0405). The weight of team was 0.1805, which influenced by the top three secondary indicators being home and away performance (0.0409), tactical execution level (0.0367), and the degree of coordination (0.0356). The weight of character of a game was 0.0785 comprising by match attributes (0.0407) and the disparity in strength between the two sides (0.0378). The weight of referee was 0.1917, which influenced by the top three secondary indicators being officiating proficiency (0.0405), judgment scale (0.0388), and team coordination (0.0384). The weight of other factors was 0.3517, which influenced by the top three secondary indicators being on-field violent incidents (0.0442), on-field special events (0.0418), and medical support measures (0.0414).

CONCLUSION: The actual playing time in CSL games was affected by multiple factors. These results provide a reference for practitioners to design effective training and formulate game strategies for elite soccer leagues. Chinese Football Association needs to set out a series of specific measures based on the weights of different factors, and encourage all relevant organizations to take measures to enhance the continuity, quality, and watchability of a match, elevating the standard of Chinese football to align with international norms.

JUMP OFF THE BEAM: FUNCTIONAL AND ANTHROPOMETRICAL CHARACTERISTICS OF ELITE BELGIAN WOMEN'S ARTISTIC GYMNASTS

DHOE, B., BOONE, J., COLOSIO, A.L.
GHENT UNIVERSITY

INTRODUCTION: Elite Womens Artistic Gymnastics is a complex sport that requires high physiological and technical demands from childhood onwards. Knowledge of the functional and anthropometrical characteristics of high level gymnasts is paramount to guide selection, training and recovery strategies throughout the growth and development (1; 2). While some information about gymnasts physiques is available, there is limited knowledge about gymnasts' functional characteristics, and a need for country-specific databases (3). Therefore, this investigation was aimed at providing up-to-date functional and anthropometrical data of elite Belgian women's artistic gymnasts.

METHODS: Between November 2021 and January 2024, we screened 19 female artistic gymnasts belonging to the Belgian national team to assess anthropometrical characteristics (i.e., height, body weight (BW), body fat%, and bone density Z-score), maximal strength (i.e., 1 rep-max (1RM) for squat, half squat, leg press, bench press, and bench pull), cardiovascular fitness (i.e., VO2max, ventilatory thresholds 1 and 2 for running), jump height and flexibility. For analysis, the most recent and complete representative values were used. Average values and standard deviation were assessed per variable.

RESULTS: Mean age at the time of screening was 17.8 ± 2.3 years, with 2 individuals categorized as junior and 17 as senior. The mean height upon screening was 158.8±6.4cm, BW was 52.1±7,6kg, bodyfat% was 20.8±4.3% and bone density Z-score was 1.2±1.1. As for mean strength values, relative 1RM to BW for squat was 1.3±0.2kg×BW-1, 2.6±0.5kg×BW-1 for half squat, 4.9±0.9kg×BW-1 for leg press, 0.9±0.1kg×BW-1 for bench press and 1.0±0.1kg×BW-1 for bench pull. Concerning mean cardiovascular fitness, VO2max was 51.3±3.4ml/min/kg, the mean ventilatory threshold 1 and 2 occurred at 68.8±4.4% and 85.1±3.6% of VO2max respectively. Regarding jumping performance, squat jump was 26.0±3.7cm, counter movement jump was 27.6±3.2cm, counter movement jump with arms was 34.9±3.6cm, single leg jump for the right leg was 15.0±2.6 and 14.9±2.7cm for the left leg. It was found that flexibility was considerably higher compared to a non-gymnast reference population, except for wrist supination which was lower (4; 5).

CONCLUSION: Our sample of elite Belgian women's artistic gymnasts have similar height, BW, VO2max and relative 1RM to BW for squat compared to values observed in other countries (6; 7). Bodyfat% is within the range but at the higher end than earlier examined (3), while jump heights were lower (6). Bone density and flexibility were higher than the non-gymnast reference population, with the exception of wrist supination which was lower (8). Finally, there is a need to integrate upper body strength measures in elite female gymnasts to allow for quantitative comparisons.

ARRHYTHMIC BURDEN IN ASYMPTOMATIC HEALTHY ULTRARUNNERS AND THE ASSOCIATION TO CARDIAC STRUCTURE AND FUNCTION

AGGOKABO, O.P., JOHNSON, C., MORRISON, B., ASHLEY, E., FROLELICHER, V., HADDAD, F., SHAVE, R., SHANTSILA, A., SPRUNG, V., LIP, G.Y.H., GEORGE, K., OXBOROUGH, D.

1LIVERPOOL JOHN MOORES UNIVERSITY, 2LIVERPOOL CENTRE FOR CARDIOVASCULAR SCIENCE, 3TRINITY WESTERN UNIVERSITY, CANADA, 4STANFORD UNIVERSITY,CALIFORNIA,USA, 5UNIVERSITY OF BRITISH COULMBIA,CANADA

INTRODUCTION: Undertaking aerobic exercise training to meet World Health Organisation guidelines is associated with positive cardiovascular benefits. There is however, evidence suggesting that very high volumes of endurance exercise training may be associated with adverse cardiac remodelling and increased prevalence of arrhythmia (including atrial fibrillation [AF]). Quantifying the burden of arrhythmia and its association with lifetime training exposure and cardiac remodelling in highly trained ultra-endurance athletes was the focus of the present study.

METHODS: 20 male (age 48 ± 10 years) and 15 female (age 47 ± 12 years) asymptomatic, healthy ultrarunners who secured a place at the 2022 Western States endurance race or were attending the pre-race training camp (California, USA), were recruited. A continuous electrocardiogram (ECG) monitor was worn for one week prior to the race/training camp providing incidence of premature atrial contractions (PACs), premature ventricular contractions (PVCs) and number of episodes of AF. A questionnaire captured lifetime training volume (MET-hr) and lifetime running miles. A full transthoracic echocardiogram was undertaken 24-48 hours before the race/training run. LV structure was defined by LV mass (LVM), end diastolic volume (EDV) and mean wall thickness (MWT) whilst function was determined by ejection fraction (EF) and global longitudinal strain (GLS). Left atrial (LA) structured was defined by LA volume (LAV). Pearsons correlation determined the association between arrhythmia burden and (1) cardiac structure and function, and (2) training exposure.

RESULTS: There was a 0.6 ± 0.8 (0-3.4%) and 0.7 ± 0.7 (0-2.6%) PAC and PVC burden, respectively. There were no episodes of AF. A weak but significant correlation was apparent between PVC burden and LVEDV (r= 0.376; P=0.044). There were no significant associations between arrhythmia burden and indices of cardiac structure and function. There were significant correlations for PAC burden (%) with lifetime training volume (MET-hr) (r=0.506 P=0.005), and lifetime running miles (r=0.367 P=0.046). PVC burden did not significantly correlate with measures of lifetime training exposure.

CONCLUSION: In a unique cohort of asymptomatic ultra-endurance athletes with significant lifetime endurance training exposure, we observed a relatively low overall arrhythmic burden and lack of AF. We observed an association between PVC burden and LV size suggesting some level of linkage between cardiac remodelling and ventricular arrhythmia burden that requires further evaluation. The association between atrial arrhythmia burden and measures of lifetime exercise exposure maybe a pre-cursor to the development of AF that could be a focus of future clinical evaluation.

THE ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION USING THE SEMITENDINOSUS TENDON MAY ADVERSELY AFFECT SPRINT RUNNING KINEMATICS EVEN SEVERAL YEARS AFTER SURGERY

UMEDA, T., KAWAMA, R.2,3, TAKAHASHI, K.2, WAKAHARA, T.1, ARAI, A.2, HOJO, T.1

1,2 DOSHISHA UNIVERSITY

INTRODUCTION: The anterior cruciate ligament (ACL) reconstruction using the Semitendinosus (ST) tendon is a common surgery. This surgery is called the ST method. It has been reported that 2 to 4 years after harvesting the ST tendon for the ACL reconstruction, the length and volume of the ST in the operated leg are shorter and smaller than those in the healthy leg 1). Previous research has shown that the ST method reduces knee flexion strength 2). Another study reported that knee flexion and extension torque correlate with sprint running velocity 3). Additionally, Sprint velocity is correlated with the volume of the ST in sprinters 4). However, there are no reports on sprint running kinematics after the ST tendon harvesting. This study aimed to investigate the ST morphology, knee flexion/extension torque, and sprint running kinematics of athletes who have undergone the ACL reconstruction using the ST methods and have returned to sports.

METHODS: Nine male patients (mean age ± SD: 21.4 ± 1.4 years old, 37.3 ± 17.2 months after surgery) participated. All patients underwent isolated unilateral the ACL reconstruction, using the ST method. Length and volume of the bilateral the ST were measured using MRI. Maximal isometric knee flexion and extension torque was measured in supine positions at every 10° from 60° to 120° of knee flexion angle using a dynamometer. Step frequency, step length, and knee flexion angle were measured in the 40-50 m interval of the 50 m sprint using high-speed cameras. These variables were calculated using KINOVEA software. Paired-sample t-test was used to analyze the differences in the ST length, the ST volume, step frequency and step length between the operated and healthy leg. Two-way ANOVA was used to analyze the differences in knee flexion torque between operated and healthy legs and between every knee flexion angle.

RESULTS: Length and volume of the ST muscle belly were significantly shorter and smaller in the operated leg than in the healthy leg ($p < 0.05$). Isometric knee flexion torque was significantly lower in the operated leg than in the healthy leg in all knee flexion angles ($p < 0.05$). Isometric knee extension torque was not significantly different between the healthy and operated legs at all knee flexion angles. During sprint running step frequency and step length were not significantly different between the healthy and operated legs. During sprint running the maximum knee flexion angle in the backward

swing phase and minimum knee flexion angle in the forward swing phase were significantly smaller in the operated leg than in the healthy leg ($p < 0.05$).

CONCLUSION: Even 37.3 months after the ACL reconstruction using the ST method, there was still the ST atrophy and decreased knee flexion torque. These factors may adversely affect sprint running kinematics. The ST methods should be used with caution.

CLINICAL EXERCISE PHYSIOLOGISTS: THE PRESENT SITUATION IN AUSTRIA

BIRKLBAUER, A., BIRKLBAUER, J.1, TSCHAKERT, G.2, HOFMANN, P.2
UNIVERSITY OF SALZBURG

INTRODUCTION: Lack of physical activity is a significant risk factor for global mortality, as evidenced by Katzmarzyk et al. (2022). Studies (e.g., Heath et al. 2022) have demonstrated the effectiveness of exercise training as a preventive and treatment strategy for a wide range of at least 26 non-communicable diseases (Pedersen & Salting 2015). Consequently, an increasing number of countries are incorporating clinical exercise physiologists (CEPs), university graduates specialized in sport and exercise science, into their healthcare systems. Given the worldwide strain on healthcare systems, CEPs are seen as a cost-effective add-on therapy to hospitals, clinics and private physician practices.

METHODS: Research has shown the necessity of personalized exercise prescriptions that adhere to the so called F.I.T.T. principle (i.e., frequency, intensity, time, and type of exercise) (Garrahy et al., 2020), underpinning the inadequacy of a one-size-fits-all approach (Duong, 2022). A comparative study by Carrard et al. (2022) showed the varying roles of CEPs within the healthcare systems of Australia and Switzerland, representing two different modern approaches. Already formally recognized as a health profession in Australia, the respective graduates are not implemented as healthcare providers in Switzerland yet. Looking at other countries like the UK, New Zealand, Canada or Hong Kong, CEPs are increasingly integrated into these healthcare systems.

RESULTS: Locally, the CEP situation in Austria is comparable with some substantial differences. Austria is a country with one of the highest per capita health expenditures among the EU countries but persistently high preventable mortality rates and even more important less healthy life years (OECD, 2023). Recently, the Austrian government legalized exercise scientists as formally accredited health-professionals (referred to as Training Therapists) within the in-patient system. Since 2012, Training Therapists are recognized as an allied healthcare profession. However, they are limited to work salaried and are not allowed to offer training therapy services in a self-employed position, being a dissatisfying solution with respect to patient care in general.

CONCLUSION: Although appropriately qualified professionals providing individually adjusted and international guideline- and evidence-based exercise interventions are available, the Austrian healthcare system is still missing this opportunity to implement Training Therapists at an individual, societal, and nation-wide level.

PREVALENCE OF URINARY INCONTINENCE IN FEMALE GYMNASTS: A SYSTEMATIC REVIEW

KNEIßLER, E., ZENTGRAF, K.
GOETHE UNIVERSITY FRANKFURT

INTRODUCTION: According to common knowledge, it is assumed that there are mainly older people, pregnant women and those who have just given birth, who suffer from urinary incontinence. However, young and healthy women being active in sports are also affected by this phenomenon. Based on the study situation, it can be assumed that people who practice high-impact sports are more prone to incontinence than others of the same age. The objective of this review is to evaluate the occurrence of urinary incontinence in female gymnasts as high-impact athletes and identify the factors most likely to contribute to it.

METHODS: A systematic review of the literature was conducted by making use of electronic databases, including PubMed, Web of Science and Cochrane Library, for studies published in the English language up to January 2024. The search strategy included the keywords stress urinary incontinence, female urinary leakage, trampoline, artistic gymnastics, cheerleading, female athletes. The subjects were female gymnasts and the outcome formed prevalence of urinary incontinence.

RESULTS: The search identified 49 studies, 6 of which met the methodologic criteria for a complete analysis. In this review, 928 women aged 13 to 44 were included. The Risk of Bias in these studies was assessed using Risk of Bias in non-randomized Cohort Studies by Cochrane and ROBINS-I depending on the type of study.

CONCLUSION: These data suggest that exercise in gymnastics show a high prevalence of urinary incontinence, mainly due to sport-specific movements. Preventive measures are also rarely taken. The leakage of urine massively influences

the athlete's quality of life and their performance in training and competition. The findings of the present review indicate a high prevalence of urinary incontinence in gymnasts. This review aims at bringing this issue into focus as it may have a major impact on well-being and involvement of females in sports.

EFFECTS OF DIFFERENT OCCLUSION PRESSURES IN BLOOD FLOW RESTRICTION TRAINING ON EXERCISE-INDUCED SKELETAL MUSCLE DAMAGE: A RANDOMIZED CONTROLLED DOUBLE-BLIND TRIAL

HAPP, K., SCHWIETE, C., NIEDERER, D., BEHRINGER, M.
GOETHE UNIVERSITY FRANKFURT

INTRODUCTION: The use of blood flow restriction (BFR) is a well established training method. However, it is still unknown whether increased metabolic stress, possibly caused by higher cuff occlusion pressures, has an additional effect on muscle damage [1]. Therefore we investigated the effects of mechanical and metabolic stress on the extent of BFR exercise-induced muscle damage.

METHODS: Forty participants (25.4 ± 3.5 years, 68.4 ± 13.1 kg, 173 ± 8.9 cm) were randomly divided into four parallel groups with different BFR occlusion pressures.

Groups were defined as no pressure (NP), low pressure (LP; 50%), medium pressure (MP; 75%) and high pressure (HP; 100%) based on the individually measured limb occlusion pressure (LOP)

Following baseline measurement, participants performed a maximum of four sets with 20 repetitions and 30 seconds rest at 30% of the 1-repetition maximum (1RM) or until reaching muscle failure.

During training, number of completed repetitions (n of reps) and oxygen saturation [%] via near-infrared spectroscopy were recorded.

Muscle damage markers such as isokinetic peak torque [Nm] during knee extension (PT) and subjective pain perception (visual analog scale; VAS) were measured before and 1h, 24h, 48h and 72h after intervention. Potential between-group differences were calculated using repeated measures ANOVAs and post-hoc 95%-confidence interval comparisons.

RESULTS: We found between-group differences in reps absolved ($F(3,16) = 50.38$, $p<.001$); with NP and LP completing more reps than MP and HP. Conversely, groups exhibited different oxygen saturation values during exercise ($F(3,17.3) = 3.23$, $p<.05$).

Results showed an effect for pain perception ($F(12,140) = 2.29$, $p = .011$, $n^2p = .078$), In particular between NP and MP/HP at 24h and 48h post intervention (MD = 2.05, SE = 0.78, t (35) = 2.6, $p < .025$), (MD = 2.07, SE = 0.76, t (35) = 2.74, $p <.025$), (MD = 2.05, SE = 0.71, t (35) = 2.87, $p < .025$), (MD = 1.59, SE = 0.69, t (35) = 2.52, $p <.05$).

Concentric PT also revealed an interaction effect of group x time with concentric baseline PT as a covariate ($F(6,60) = 3.56$, $p = .004$, $n^2p = .263$). Post-hoc confidence interval comparisons show a higher PT reduction for NP compared to MP and HP and for LP compared to HP at 24h post (NP, *M* = 178, 95%CI [165, 190]), (LP, *M* = 181, 95%CI [170, 193]), (MP, *M* = 191, 95%CI [180, 203]), (HP, *M* = 195, 95%CI [183, 207]).

CONCLUSION: Training with LP BFR demonstrated muscle damage comparable to non-BFR training, while MP and HP groups showed less muscle damage based on PT reduction, combined with fewer symptoms as evident by lower VAS values. Based on our findings, we assume that higher total load serves as the primary trigger for muscle damage.

[1] Loenneke JP, Thiebaud RS, Abe T. Does blood flow restriction result in skeletal muscle damage? A critical review of available evidence. Scand J Med Sci Sports. 2014 Dec;24(6):e415-422. doi: 10.1111/sms.

THE ROLE OF MUSCLE STRENGTH CAPACITIES FOR KNEE KINEMATICS DURING DOWNHILL HIKING WITH TOTAL KNEE ARTHROPLASTY AFTER A TRAINING INTERVENTION

BLEUEL, J., WILLWACHER, S., MITTENDORFER, I., DEBERTIN, D., MOHR, M., MICHEL, B.
MEDICAL CENTER GARMISCH-PARTENKIRCHEN

INTRODUCTION: During downhill hiking, people with unilateral knee arthroplasty (uKA) show muscular deficits and stiff knee gait patterns compared to healthy controls [1]. We hypothesized that a 12-week training intervention counteracts the muscular deficits and that the muscular improvements contribute to more physiologic knee joint kinematics during downhill hiking.

METHODS: Thirty-five participants (266 ± 87 days post surgery) with uKA (INT) conducted a 12-week muscle strength training intervention (3 training sessions á 45 minutes per week). Before (PRE) and after (POST) the intervention, the following measurements took place: Participants walked on a predetermined walking trail at a self-selected pace wearing an inertial sensor system (XSens, Awinda, Enschede, Netherlands) to record the 3d kinematics of the lower extremities. We evaluated the peak knee flexion (PKF) and the range of motion (ROM) of the affected leg during shock absorption (25% of the gait cycle) at two different down-slopes (10% and 25% gradient). In addition, we measured the concentric and eccentric lower extremity isokinetic muscle strength (Isomed2000, D. & R. Ferstl GmbH, Hemau, Germany) of the knee flexors and extensors of the affected leg at two angular velocities (50°/sec, 120°/sec). Fourteen controls with uKA, matched for age, BMI, and days since surgery, were also measured; however, they did not perform the training intervention program (CON).

RESULTS: Muscle strength (identified as body mass normalized peak torque; Nm/kg) improved significantly from PRE to POST for both muscle groups and all tested conditions by 10-47 % (INT) and by 3-25 % (CON) ($p < 0.05$). PKF and ROM while walking downhill at the moderate slope increased from 18.3 ± 8.6 to 22.6 ± 9.3 (PKF) and 11.8 ± 4.2 to 14.4 ± 4.2

(ROM) in INT and from 18.6 ± 7.3 to 21.9 ± 4.5 (PKF) and 12.1 ± 3.7 to 15.7 ± 3.2 in CON ($p < 0.01$). Concerning the steep slope, values developed from 25.6° ± 7.7° to 27.5° ± 6.8° (PKF) and 14.9° ± 4.0° to 16.6° ± 4.2° (ROM) in INT and from 22.9° ± 8.3° to 23.4 ± 5.5 and 13.8 ± 3.6 to 16.0 ± 2.3 in CON ($p < 0.01$). No interaction effect between time and group was found ($p > 0.05$). Improvements in hamstrings and quadriceps strength values were correlated positively with ΔPKF (PKF POST-PKF PRE) and ΔROM (ROM POST-ROM PRE) at both downhill slopes in INT. Parameters correlated less in CON.

CONCLUSION: Muscle strength improvements played a significant role in developing more physiologic knee kinematics during downhill hiking in persons with uKA. However, the lack of time by group interactions for strength improvements indicate that the additional strength training program might not have significantly increased strength capacities compared to standard rehabilitation, highlighting the potential for future studies using more intense or more prolonged training intervention. CARDIAC FUNCTION DURING CARDIOPULMONARY EXERCISE TESTING IN PATIENTS WITH HEART FAILURE WITH PRESERVED EJECTION FRACTION

SCHOCH, R., KRÖPFL, J., GASSER, B., DIETERLE, T., SCHMIDT-TRUCKSÄSS, A.

UNIVERSITY OF BASEL

INTRODUCTION: Patients with heart failure with preserved ejection fraction (HFpEF) are commonly characterized by impaired exercise capacity, typically assessed through cardiopulmonary exercise testing. A key parameter in this assessment is maximal oxygen consumption (VO2peak), derived from the product of cardiac output (CO) and arterio-venous oxygen difference (a-vDO2). The ability to evaluate CO non-invasively during exercise enables the calculation of a-vDO2, thus providing comprehensive insights in circulatory function during cardiopulmonary exercise testing. This study aims to clarify the determinants contributing to reduced exercise capacity in patients with HFpEF.

METHODS: Forty patients with HFpEF underwent cardiopulmonary exercise testing. Gas exchange parameters were assessed via breath-by-breath analysis (MetaMax 2B, Cortex Biophysik GmbH, Leipzig, Germany), while CO was measured using Physioflow® (Manatec Biomedical, Poisy, France) and a-vDO2 was subsequently calculated. Patients were stratified into two groups based on the median of absolute VO2peak for further analysis.

RESULTS: Median of VO2peak was 1.50L/min. Group with patients with lower exercise capacity (<1.50 L/min) demonstrated lower CO (12.67(3.07) vs. 14.99(3.26) L/min, p=0.032), and lower stroke volume (92.1(23.5) vs. 107.2(18.0) mL, p=0.036), compared to the other group. However, there were no significant differences observed in age (73(10) vs. 69(11) years, p=0.233), BMI (24.8(4.9) vs. 27.8(5.3) kg/m2, p=0.068), a-vDO2 (11.0(3.5) vs. 12.8(3.3) mL/100mL, p=0.131), peak heart rate (139(17) vs. 145(19) bpm, p=0.306), or respiratory exchange ratio (1.06(0.06) vs 1.05(0.04), p=0.303).

CONCLUSION: The associations between reduced exercise capacity, lower cardiac output, and stroke volume among patients with HFpEF indicate an inability to increase stroke volume via the Frank-Starling mechanism while chronotropic incompetence or peripheral vascular dysfunction may not be as decisive as discussed elsewhere. These findings underline the potential utility of targeted exercise interventions aimed at improving cardiac function to increase exercise tolerance in patients with HFpEF.

POST-EXERCISE SERUM IMPROVED THE IGF-1 EFFECT ON PROTEIN SYNTHESIS OF TENDON CONSTRUCTS AND SHOWED NO CORRELATION WITH IGF-1/IGFBP3 SERUM LEVELS ON COLLAGEN SYNTHESIS.

GARRIDO, P.M., PAPADOPETRAKI, A., SVENSSON, R.B., MAGNUSSON, S.P., PHILIPPOU, A., BACKMAN, L.B., GIANNOPOULOS, A.

LOUGHBORUGH UNIVERSITY

INTRODUCTION: Insulin-like Growth Factor-1 (IGF-1) has a regulatory role in tendon healing and IGF-1 injections have been used as a treatment in tendinopathies. Exercise alters systemic responses which can have anabolic or catabolic actions. The purpose of this study was to assess if the baseline levels of IGF-1 or Insulin-like growth factor-binding protein 3, (IGFBP-3) in the serum would affect the bioactivity of exogenously added IGF-1 on tendon constructs regeneration capacity.

METHODS: Seven healthy females that were physically active but not professional athletes volunteered for this study (age: 30.86 ± 5.05 years, height: 1.66 ± 0.03 m, body weight: 61.93 ± 4.31 kg, body mass index: 22.55 ± 1.42 kg/m2). Participants conducted a cardiopulmonary exercise testing (CPET) protocol, consisting of a maximal incremental protocol on a cycle ergometer with 3-minute stages, aiming to last 8-12 minutes. During the test, gas exchange was monitored continuously, through a breath-by-breath exercise metabolic analyzer. On a separate day, the participants performed one exercise session on a cycle ergometer at 80% of their peak oxygen uptake (VO2peak) and serum was collected before and after the exercise session. Human tendon constructs (N=56) treated with serum from each participant consisting of the following conditions: Pre- (Pre-Ex+IGF-1) and post-exercise serum (Post-Ex+IGF-1) supplemented with IGF-1, pre- (Pre-Ex) and post-exercise (Post-Ex) serum without IGF-1. Enzyme-linked immunosorbent assays were used to evaluate serum levels of IGF-1 and IGFBP-3 and collagen type I in the cultured media. Protein concentration was measured with Bicinchoninic acid assay.

RESULTS: Free IGF-1 levels in the circulation showed a 30.6% increase as measured in post-exercise serum compared to pre-exercise values. IGFBP-3 remained unaltered after the exercise session. Treatment with IGF-1 had a significant negative effect on collagen type I overall secretion (p=0.03) with a 9.5 % decrease of Pre-Ex+IGF-1 and 28.6% of Post-Ex+IGF-1 compared to Pre-Ex and Post-Ex groups respectively, with no significant correlation with IGF-1 or IGFBP-3 serum levels.

Both exercise (p=0,014) and IGF-1 treatment (p<0.0001) altered the total protein concentration. The supplementation of IGF-1 resulted in increased protein synthesis at the pre-exercise (Pre-Ex+IGF-1>Pre-Ex, p=0.06) by 28.2% and the post-exercise (Post-Ex+IGF-1>Post-Ex, p=0.0005) by 31.8% compared to the relative groups before the exercise.

CONCLUSION: IGF-1 treatment caused a reduction of the secreted collagen type I indicating that more collagen was incorporated into the construct structure. The above process did not correlate with the amount of IGF-1 and IGFBP3 in the serum, suggesting that treatment efficacy depends more on the administrative dose. Post-serum systemic environment enhanced IGF-1 effect on protein synthesis of tendon constructs providing a useful condition that could be considered for designing treatment strategies targeting tendon regeneration.

INJURY INCIDENCE AMONG STUDENT-ATHLETES WHEN COMBINING ACADEMIC STUDIES AND ELITE SPORTS IN SWEDEN - A PROSPECTIVE COHORT STUDY.

TERVO, T., TENGMAN, E., MÅRS, T., FLATHOLM, E.

UMEÅ SCHOOL OF SPORTS SCIENCES

INTRODUCTION: Sports injuries are a widespread concern among collegiate athletes (1), sometimes leading to unexpected ends to athletic careers. Various models of dual career systems have been introduced for combining elite sports and academic studies, acknowledging the need for alternative pathways (2). However, managing dual careers can be demanding for students, particularly in the initial academic year due to elevated pressure and low academic function (3).

The purpose of the present study was to examine the injury incidence among student-athletes during the first year of studying as well as to identify risk factors for injury in this population.

METHODS: Two surveys were employed, one year apart, between 2018 and 2022 at a University in Sweden. Two-hundred and forty-three student-athletes (101 men, 142 women, mean age: 22,1 [18-36]) responded to a baseline survey in conjunction with their first semester of study. The one-year follow-up survey was answered by 111 student-athletes (47 men, 64 women, mean age: 22,9 [19-37]). The survey addressed the sports student's injury occasions, injury characteristics, sports participated in, experienced stress, recovery methods, management of leisure time and study pace. Independent samples t-test, chi-square test, univariate and multivariate regression were used in the analysis.

RESULTS: Fifty-one percent of the students reported having sustained an injury on some occasion the year before study start. Moreover, during the one-year follow-up, 54% of the students reported an injury during the first year of studying. The students reporting an injury prior to study start were more likely to sustain a new injury during the first year of studying (OR=3.174, p=>0.01). Sex, type of sport participated in, psychological stress, study pace, relaxation management, and leisure time management were not associated with an increased injury risk in this population.

CONCLUSION: Findings from the present study indicates that injury one year prior to study start aggravates injury risk during the first year of studies for these student-athletes. Experienced stress was not found as an injury predictor in this population which may emphasizes the importance of having a supportive environment around the student-athletes, however, more research is needed to investigate this further. Considering the high prevalence of injury incidence found in this study, developing preventive methods is key.

A FUNCTIONAL APPROACH IN AN ELITE SPORT PERFORMANCE CENTRE: FROM THE MOVEMENT ASSESSMENT TO THE INJURY PREVENTION USING A NEW TESTING PROTOCOL

GARGAGLI, M., BAUDRY, T.

CREPS TOULOUSE

INTRODUCTION: According to the observations conducted in an elite sport performance centre, 71% of athletes experience injury during the sporting season. Joining the centre implies an increase of training load, thereby elevating the risk of injury [1]. Additionally, downtime due to injuries is significantly linked with a decrease in performance [2]. We aimed to characterise the functional capacities of athletes to better prevent the occurrence of injury.

METHODS: Four hundred and fifty French elite athletes from thirteen sports development programmes participated in this three-year retrospective study. Each athlete was evaluated through the Mobility and Stability Screen (M2S), a functional assessment consisting of thirteen exercises (seven exercises were lateralised). The binary notation system led to a twenty-point score. Each athlete was evaluated twice: at the beginning and at the end of the season. Corrective protocols of five exercises performed at least three times a week were set up for each athlete, aiming at improving an anatomical location mobility or stability. Injury reports were collected by the centre' doctors, reporting 1353 de-identified injuries. Functional tests' scores and blinded injury reports were analysed considering different variables: sport, status (new or old in the structure), moment of the season and injuries details.

RESULTS: The average M2S score was 9.54±4.06 over 20 points. Sport (Kruskal-Wallis-chi-squared=115.23; p=2.2e-16) and status (F=12.12;p=5.67e-05) had a significant impact on the M2S score. Rugby league achieved the lowest scores (6.77 ± 2.66), while aerobic received the highest scores (16.15 ± 3.05). New athletes had an average score two points lower than old athletes. Each athlete increased their mean score by two points between pre-test and post-test (F-value=1.73;p=0.10) on the body part trained as part of the routine protocol (Z-value=4.76;p=1.94e-06). Considering location, 54% of the injuries were located on the lower limbs, 23% on the upper limbs, 23% on the back, head and trunk. September, October and November concentrated 46% of all injuries, representing the riskiest period. Finally, logistic regression showed that athletes with less than 10 points had a 76% chance of being injured, while those with more than 15 points had a 50% chance of being injured.

CONCLUSION: Various factors could influence the functional score of each athlete. However, the progression of the M2S score over the season showed that the routines and regular training were effective in developing functional qualities and that high functional scores led to a significant decrease in the probability of injury.

INGESTION OF A SINGLE BOLUS OF MEALWORM-DERIVED PROTEIN DOES NOT INCREASE MUSCLE PROTEIN SYNTHESIS RATES DURING RECOVERY FROM RUNNING EXERCISE IN HEALTHY, YOUNG MALES AND FEMALES

HERMANS, W., PAPPA, S., KUIN, L., HENDRIKS, F., VERDIJK, L., VAN LOON, L.
MAASTRICHT UNIVERSITY

INTRODUCTION: It has been well-established that milk protein ingestion following resistance-type exercise stimulates muscle protein synthesis. Recently, we have shown that also mealworm–derived protein ingestion further increases muscle protein synthesis rates following a single bout of resistance-type exercise. Less work has been performed on the proposed efficacy of protein ingestion to augment muscle protein synthesis rates during recovery from endurance-type exercise. Here, we assessed the impact of ingesting mealworm-derived protein on muscle protein synthesis rates during recovery from a single bout of running exercise in healthy, young males and females.

METHODS: In this randomized, double-blind, cross-over intervention trial with a 4±2 week washout between treatments, 10 males and 10 females (Age 23±3 y, BMI 23.3±2.4 kg/m2, VO2max 49±7 mL/kg) ingested a drink with either 0.38 g protein/kg body mass (22-35 g) lesser mealworm-derived protein (69% protein concentrate; MDP) or flavoured water (placebo; PLA) following a 40-minute treadmill run at 85±6% of maximal heart rate. Primed, continuous intravenous L-[ring-13C6]-phenylalanine infusions were combined with frequent collection of blood and muscle tissue samples to assess 0-3, 3-6, and 0-6 h post-exercise muscle protein synthesis rates. The main outcome, 0-6 h post-exercise muscle protein synthesis rate, was analyzed with a paired t-test. Time-dependent variables were analyzed using repeated measures ANOVA with time and treatment (MDP vs PLA) as within-subjects factors, an α-level of 0.05, and appropriate post-hoc testing in case of significant interactions. Data represent means±SD; ηp and cohen's d are reported for effect size.

RESULTS: Ingestion of MDP strongly increased plasma total amino acid and leucine concentrations (both Time: P<0.001), with peak values being reached 30 minutes after ingestion after which they returned back to baseline, while no changes in plasma amino acid concentrations were observed in the PLA treatment (both: Time*Treatment: P<0.001; ηp=0.9). Muscle protein synthesis rates averaged 0.054±0.023 vs 0.055±0.025 %/h during the 0-3 h post-exercise recovery period, and 0.044±0.020 vs 0.049±0.018 during the 3-6 h post-exercise recovery period with MDP vs PLA, respectively, with no differences between treatments (Time*Treatment: P=0.52; ηp<0.1; Time: P=0.16; ηp=0.1; Treatment: P=0.44; ηp<0.1). Overall, muscle protein synthesis rates averaged 0.050±0.016 vs 0.052±0.017 %/h during the entire 6 h post-exercise recovery period with MDP vs PLA, respectively, with no difference between treatments (P=0.46; d=0.2).

CONCLUSION: Ingestion of 0.38 g protein/kg body mass of a mealworm-derived protein does not increase muscle protein synthesis rates during recovery from a single bout of running exercise in healthy, young males and females.

MILK PROTEIN GLYCATION DOES NOT COMPROMISE THE POST-PRANDIAL MUSCLE PROTEIN SYNTHETIC RESPONSE DURING RECOVERY FROM RESISTANCE EXERCISE IN MEN

VAN LIESHOUT, G., TROMMELEN, J., HENDRIKS, F., NYAKAYIRU, J., VAN KRANENBURG, J., SENDEN, J., GOESSENS, J., GIJSSEN, A., VERDIJK, L., BRAGT, M., VAN LOON, L.
MAASTRICHT UNIVERSITY

INTRODUCTION: Industrial processing and storage of milk products can strongly increase protein glycation level. Previously, we have reported that a high protein glycation level compromises protein digestion, resulting in an attenuated post-prandial rise in circulating plasma lysine concentrations. The compromised post-prandial lysine availability may restrict

the anabolic properties of such a highly glycated protein. The present study assessed the impact of the level of milk protein glycation on post-prandial plasma amino acid availability and subsequent muscle protein synthesis rates during recovery from a single bout of exercise.

METHODS: 45 recreationally active, healthy young men participated in this randomized parallel study. Immediately after performing a single bout of whole-body resistance-type exercise, subjects ingested either 20 g milk protein with a low (4%; LOW) or high (47%; HIGH) glycation level plus 2 g free leucine, or a non-caloric placebo (PLA). Continuous intravenous infusions of L-[ring-13C6]-phenylalanine were applied, with blood and muscle tissue samples being collected during a 6 h post-prandial period to evaluate plasma amino acid concentrations and post-prandial muscle protein synthesis rates. Incremental area under the curve and peak concentration for plasma amino acid concentrations and muscle protein synthesis rates were compared between treatments using a one-way ANOVA with a Bonferroni correction. Plasma amino acid concentrations were compared between treatments by two-factor repeated-measures ANOVA with time as within-subject factor and treatment as between-subject factor.

RESULTS: Protein ingestion increased plasma total and essential amino acid concentrations compared to placebo (time*treatment effect: P<0.001), with no significant differences between the milk protein with the low or high glycation level. Post-prandial plasma lysine concentrations were higher following protein ingestion (time*treatment effect: P<0.001), with on average 28% lower peak lysine concentrations following ingestion of the protein with the high versus low glycation level (191±23 vs 266±47 mmol·L-1, respectively, P<0.001). Post-prandial plasma lysine availability, assessed over the full 6 h period, was substantially lower following ingestion of the protein with the high versus low glycation level (-5±7 vs 10±9 mmol·L-1·6 h-1, respectively, P<0.001). Post-prandial muscle protein synthesis rates did not differ between treatments (0.059±0.016, 0.061±0.012, and 0.061±0.018 %·h-1, in LOW, HIGH and PLA, respectively, P=0.939).

CONCLUSION: Ingestion of a protein with a higher glycation level compromises the post-prandial increase in plasma lysine availability. Milk protein glycation does not seem to modulate the post-prandial muscle protein synthetic response during recovery from resistance exercise in healthy men.

FOUR WEEKS OF MEDIUM-CHAIN TRIGLYCERIDES INTAKE WITH/WITHOUT MODERATE-INTENSITY AEROBIC EXERCISE ADVANCES WORKING MEMORY IMPROVEMENT IN HEALTHY YOUNG MEN

YUUKI, I.W., DORA, K.1,2, MATSUMURA, T.1, FUKUZAWA, K.1, MURAKAMI, Y.1, HASHIMOTO, K.1, HASHIMOTO, T.1, TSUKAMOTO, H.3

RITSUMEIKAN UNIVERSITY. 1>, TOYO UNIVERSITY. 2>, WASEDA UNIVERSITY. 3>

INTRODUCTION: Cognitive function can be improved by the antioxidative effects of some oil consumption habits (1-3). Among them, compared to regular long-chain triglycerides (LCT; e.g., olive oil) consumption, medium-chain triglycerides (MCT; e.g., coconut oil) are quickly absorbed and promote the production of ketone bodies which are an important energy substrate for the brain (4). Indeed, the positive MCT impact on cognitive function has been observed in various populations (1,5). Along with the aforementioned advantages, it is possible that the positive MCT impact on cognitive function is greater than the LCT impact but there is a lack of research directly comparing the long-term effects of LCT and MCT on cognitive function in healthy young individuals. Meanwhile, it is well known that long-term aerobic exercise (AE) improves cognitive function (6). Given the additive effect of AE to dietary intervention on cognitive improvement (7), it is assumed that compared with MCT alone, a combination of MCT and AE (MCT-AE) further improves cognitive function. Here, we compared the long-term effect of LCT, MCT, and MCT-AE on working memory (WM) which is one of the major cognitive functions.

METHODS: Thirty healthy young men were randomly allocated into the LCT [n = 10, age 21 ± 1], MCT [n = 10, age 21 ± 1], and MCT-AE [n = 10, age 21 ± 1] groups. All participants took the 16.3 ml oil (LCT: Olive oil; MCT and MCT-AE: MCT oil, containing 12 g MCT) every morning for four weeks in a single-blind manner. During four weeks of oil intervention, participants in the MCT-AE group performed moderate-intensity cycling AE (30 min/time, 3 times/week). Exercise intensity was determined using heart rate reserve (HRR), and moderate intensity at the onset of AE was defined at 50%HRR (but the workload was decreased if HR during AE exceeded 70%HRR due to cardiac drift). WM was assessed before and after the intervention using the face n-back task. The number of errors (ERR) and reaction time (RT) of the face n-back task were measured. The changes in ERR and RT from pre- to post-intervention were compared using the Kruskal-Wallis test and Mann-Whitney U test for post-hoc. The statistical significance level was defined at $P < 0.050$ and the Bonferroni correction was applied for post-hoc analysis.

RESULTS: The changes in ERR were similar between all groups ($P > 0.050$). Compared with the LCT group (22 [-5 – 42] ms; median [IQR]), the changes in RT were shorter in the MCT-AE group (-63 [-91 – -31] ms, $P = 0.044$) and MCT group (-29 [-50 – -6] ms; $P = 0.035$). However, regarding the changes in RT, there were no significant differences between the MCT-AE and MCT groups ($P = 0.371$).

CONCLUSION: Compared with LCT intervention, four weeks of MCT advances WM improvement in healthy young individuals. On the other hand, AE during MCT intervention did not cause further WM improvement.

POST-EXERCISE INGESTION OF 200 G OF ICE SLURRY DOES NOT DELAY THE RATE OF GASTRIC EMPTYING

YAMAGUCHI, H., HIROE, Y., YAMAMOTO, Y., MORI, T., HANANO, H., OISHI, K., IKEUE, K., ISHII, K.

DOSHISHA UNIVERSITY

INTRODUCTION: Ice slurry ingestion has attracted attention as an effective way to suppress the exercise-associated rise in core body temperature [1]. Heat countermeasures, including heat stroke, control excessive increase in body temperature and ensure efficient absorption of ingested fluids by the body. Gastric emptying rate (GER) is indicative of fluid absorption, and delayed GER results in delayed absorption of water and nutrients, leading to decreased performance. After exercise, taking measures to avoid delaying GER is crucial to replenish lost fluids and electrolytes. Previous studies have reported transient and minor effect of the ingested beverage temperature (4–50°C) on GER [2,3]; however, thus far, the effect of ingesting ice slurry (–1°C) on GER remains unclear. Understanding the effect of ice slurry ingestion on GER could inform recommendations for optimal fluid intake methods during exercise. This study aimed to determine the effect of ice slurry ingestion after exercise on gastric emptying.

METHODS: Nine healthy male students (22.3 ± 2.0 years, 169.3 ± 2.7 cm, 64.9 ± 11.2 kg) were recruited. They performed cycling exercises in the laboratory for 20 min at 60% VO2max and then ingested either 200 g of ice slurry (–1°C) or fluid (4°C) prepared with sports drinks on separate days. GER (evaluated by 13C excretion after 13C labeled sodium acetate ingestion), thermal sensation (TS), thermal comfort (TC), and gastric discomfort (GD) were evaluated after consuming each beverage.

RESULTS: No significant interaction (condition × time) was observed for changes in 13C excretion (interaction: p=0.100, condition: p=0.290, time: p<0.001). The time to maximal 13C excretion rate (Tmax) (an indication of GER) did not significantly differ between ice slurry (33.3 ± 11.9 min) and fluid (32.8 ± 7.5 min) ingestion (p=0.834). No systematic error in Tmax was found between ice slurry and fluid ingestion (95% confidence interval [CI]: –14.503–15.614, B=0.507, p=0.081). Additionally, the TS, TC, and GD did not differ significantly (TS, interaction: p=0.368, condition: p=1.000, time: p<0.001; TC, interaction: p=0.395, condition: p=0.672, time: p<0.001; GD, interaction: p=0.100, condition: p=0.218, time: p=0.100).

CONCLUSION: These findings suggest that ice slurry ingestion (200 g) after 20 min of cycling exercise does not cause a delay in gastric emptying compared to that with fluid ingestion.

EFFECTS OF EITHER A SHORT-TERM VEGAN OR OMNIVOROUS DIET WITH RESISTANCE TRAINING ON THE EXPRESSION OF GENES REGULATING MITOCHONDRIAL BIOGENESIS, INFLAMMATION, AND PROTEIN TURNOVER IN YOUNG MALES

CAMERA, D., AL REFAI, W., COOKE, M., KEENAN, S.

SWINBURNE UNIVERSITY OF TECHNOLOGY

INTRODUCTION: Appropriate nutritional support is essential to maximize the beneficial effects of exercise training. Protein ingestion can positively regulate expression of genes implicated in skeletal muscle protein turnover and metabolism. However, a limitation to the current knowledge of gene expression responses after exercise with protein intake is that most studies have been confined to the ingestion of free/ intact amino acids and/ or animal-based proteins. In contrast, little is known about changes in gene expression in response to plant-based proteins which is surprising considering the majority of dietary protein intake worldwide is derived from plant-based sources. The primary aim of this study was to compare the effects of either a short-term (i.e., 2-weeks) vegan or omnivorous diet on the expression of select genes implicated in skeletal muscle mitochondrial biogenesis, inflammation, and protein turnover in recreationally active males.

METHODS: Twenty, recreationally active and otherwise healthy male participants were recruited. A between-subjects design was employed where participants were pair-matched for leg press and extension strength as well as body mass and allocated to either a vegan (n = 10; Age: 25.6 ± 5.2 years; BMI: 25.9 ± 4.8; Leg Press 1-Rep Max: 170.6 ± 61.3 kg; mean ± standard deviation) or omnivorous (n = 10; Age: 26.2 ± 3.9 years; BMI: 25.0 ± 2.1; Leg Press 1-Rep Max: 166.0 ± 71.3 kg; mean ± standard deviation) group. Following preliminary testing, participants consumed a dietary control meal the evening prior to commencing the 14-day diet and exercise intervention period. For this intervention, participants consumed either a vegan diet (54% Carbohydrate, 26% Fat, 19% Protein; 1.6g protein/kg body mass/day) or omnivorous diet (48% Carbohydrate, 32% Fat, 18% Protein; 1.6g protein/kg body mass/day) and undertook six sessions of resistance exercise throughout the 14-day period. Skeletal muscle samples from the vastus lateralis were collected pre-, mid-, and post-intervention.

RESULTS: Taqman gene expression primers will be used to measure the expression of genes implicated in skeletal muscle mitochondrial biogenesis (PGC-1alpha, Tfam), inflammation (IL-6, TNF-alpha) and protein turnover (MuRF-1, Atrogin-1,

Myostatin, IGF-1). The expression of these markers will be analyzed pre-intervention, as well as mid- and post-intervention. Changes in expression will be normalized to GAPDH.

CONCLUSION: Findings from this work will be the first to report changes in gene expression in human skeletal muscle comparing the short-term effects of either a vegan or omnivorous diet in young, recreationally trained individuals. Such findings will be important to provide a mechanistic basis to physiological adaptation responses with each diet when combined with resistance training. Moreover, this work will advance knowledge of the capacity for vegan diets to mediate changes in gene expression pertinent to skeletal muscle adaptation responses with exercise.

FIVE WEEKS OF HIGH-CALORIE KETOGENIC DIET PROGRAM AND STRENGTH TRAINING: PERFORMANCE, BODY COMPOSITION, BIOCHEMICHEMISTRY, HORMONE AND MICRORNA EVALUATION.

CANNATARO, R., CIONE, E., ZOTTOLA, D., LEVI-MICHELI, M., GRIMALDI, A., KREIDER, R.B., BONILLA, D.A.

UNIVERSITY OF CALABRIA

INTRODUCTION: The ketogenic diet (a nutritional program that provides for a minimal carbohydrate intake, i.e., <30g or 5% of caloric intake per day) is now used not only with the aim of weight loss but also to support the management of various pathologies (headaches, GLUT1 deficiency, epilepsy, PCOS, lipedema even cancer), therefore also used for medium-long periods and not in caloric restriction¸ our idea is to be able to prove that it is possible (even if it is probably not the best way) to obtain positive results in terms of strength training even in a ketogenic regime.

METHODS: 12 subjects, six males and six females, with training experience of at least two years, aged between 20 and 50, followed a high-calorie ketogenic diet protocol (set based on a food diary) combined with weight training based on cluster sets of bioelectric parameters (bioimpedance) and fat percentage (ultrasound) were evaluated; strength assessment (1RM, CMJ tight pull on force deck); blood tests with biochemical and hormonal profiles at the beginning of the study and after five weeks; ketonemia was measured every five days at the fingertip; training and nutritional plans were constantly supervised.

RESULTS: Subjects reported, on average, a 2.3% weight decrease (most likely due to glycogen and associated water depletion), a 5% increase in phase angle, and 3.6% in LMI (bioelectric parameters positively correlated with fitness and muscle mass); a 7.7% decrease in fat percentage; an increase in the 1RM of squat, deadlift, and bench press, respectively of 8.7%, 29.7%, and 11.1%, while the CMJ is practically unchanged and there is a 3% improvement in the tight isometric pull; there is a marked increase in total cholesterol of 17.6% cos+ as well as in TGA and GOT (+29 2 and +22%); GH shows an increase of 162%, testosterone increases in men by 6% while decreases in women by 22%; insulin and cortisol show a decrease of 1.5 and 2.1%; finally the reticulocyte shows an increase of 14%; the TSH decreases by 3%; miR-206 showed an upregulation.

CONCLUSION: It can be concluded that the proposed scheme allowed the subjects to report significant improvements in terms of strength and body composition; in our opinion, the most interesting data concerns the increase in GH (recorded for both sexes) and testosterone (only in males) which could explain the effectiveness of the program even in the almost complete lack of carbohydrates; another interesting finding is the upregulation of miR-206 confirming a positive action on myogenesis, myofusion, and satellite cells differentiation; the only point to re-evaluate is the increase in cholesterol (even with a ratio with HDL still within the norm), but this occurred mainly in males, as the caloric intake exceeded 3000kcal of which at least half was fat.

DIFFERENT CARBOHYDRATE INGESTION PATTERNS DO NOT EFFECT SUBSTRATE OXIDATION, PHYSIOLOGICAL RESPONSES, GASTROINTESTINAL DISCOMFORT AND EXERCISE CAPACITY IN ENDURANCE CYCLING

JONES, R.O., ARETA, J.L., PUGH, J.N., VAZ DE OLIVEIRA, M., LOUIS, J.B.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Carbohydrate (CHO) intake during prolonged moderate-high intensity cycling is essential for endurance performance, with current research advocating high CHO intake equal to or >90 grams/hour (g/h) in long duration events [1,2]. High CHO intake can be a challenge in race conditions, requiring regular feedings per hour, likely impacting race 'flow'. However, the effects of different CHO ingestion patterns on substrate oxidation, physiological responses to exercise, gastrointestinal (GI) discomfort and exercise capacity have never been reported in cycling.

METHODS: 20 recreationally active males (maximal oxygen uptake 50.4±3.8 mL/kg/min) completed 2 experimental trials consisting of 180 min cycling (Lode, Netherlands) at an intensity equivalent to lactate threshold (LT; 139±29 W). 24 h pre-trial, a meal plan providing high CHO availability and standardised fat and protein intake was followed (8, 1 and 2 grams per kg of body mass respectively). Trial order was randomised with participants consuming 90 g/h of CHO, either as a 22.5g CHO gel every 15 min (CHO-15) or a 45g CHO gel every 30 min (CHO-30) of exercise. Blood glucose, lactate and GI discomfort symptoms were measured every 15 min using capillary blood samples and a visual analogue scale, respectively. Respiratory gases were collected in the last 2 of every 15 min with a metabolic cart (Vyntus CPX, UK). Stoichiometric equations were used to determine substrate oxidation [3]. Participants then completed an exercise capacity test to exhaustion at an intensity equivalent to 150% LT (209±43 W). Two-way repeated measures ANOVA was used to determine main effects and interactions for physiological data. Paired t-tests were used for exercise capacity and sum of scores for each GI symptom. Significance was set at $P<0.05$. All data is presented as mean ±SD.

RESULTS: Mean CHO oxidation was similar (2.38±0.06 vs 2.33±0.07 g/min for CHO-15 and -30) for both conditions ($P=0.25$), which stayed consistent over time ($P=0.09$). Fat oxidation increased ~2-fold by 180 min of exercise (time effect,

P<0.001) in both trials (treatment effect, P=0.09). Absolute oxygen uptake, blood glucose and lactate responded similarly in both trials (P=0.79, P=0.92 and P=0.34 respectively). Oxygen uptake gradually increased throughout exercise, reaching significance in the final 45 min (P<0.05), whilst glucose and lactate changed from baseline (time main effect, P<0.001). There was no significant difference between conditions for any GI discomfort symptoms (P>0.30) and exercise capacity did not differ (P=0.51) between CHO-15 and -30 (552±400 vs 612±512 seconds respectively).

CONCLUSION: Ingesting larger CHO quantities at less regular intervals during prolonged cycling can provide a more practical approach to fuelling, with minimal impact on substrate oxidation, physiological responses to exercise, GI discomfort symptoms and exercise capacity.

EFFECT OF DIFFERENT ENERGY AVAILABILITY LEVELS ON NOCTURNAL INTERSTITIAL FLUID GLUCOSE CONCENTRATIONS IN ELITE TRIATHLETES

HIROMATSU, C., GOTO, K.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Triathletes are exposed to higher energetic demands, leading to increased risk of lowered energy availability (EA) compared with other types of athletes (Jesus et al., 2022). Sustained low EA (LEA) distributes both impairments of health and exercise performance (Mountjoy et al., 2023). Sedentary women in LEA state caused substantial decrease in nocturnal blood glucose and 24 h average blood glucose concentrations compared with those in sufficient energy balanced state (Loucks et al., 2003). However, the effect of different EA levels on 24 h glucose changes in elite endurance athletes is not clear. We examined the effect of different EA levels on 24 h changes in interstitial fluid glucose concentrations (IGC) in elite male triathletes during training camp.

METHODS: Three elite male triathletes (athlete A, B, C) were continuously evaluated IGC changes for four consecutive days (days 1-4). Subjects recorded daily activities in detail. Training log was classified using METs, and exercise energy expenditure (EEE) were then estimated. To prevent overestimation, EEE was adjusted to remove calories contributed by resting energy expenditure for the duration of the exercise (Jesus et al., 2022). All subjects completed same training from days 1-3. On day 4, subjects conducted different training regimen individually. Energy and macronutrients intakes were evaluated by dietary survey. We could not measure IGC between 21:00 and 23:00 due to the error of measuring device.

RESULTS: No significant relationship was found between EA and average nocturnal (0:00-7:00) IGC ($r^2 = 0.039$, $p = 0.538$). During 4 days, the relative time (%) of IGC above 100 mg/dL during the nocturnal time was substantially high, 100% for athlete A, 94% for athlete B, and 75% for athlete C, respectively. However, among the 4-day measurements of the three athletes, the lowest EA was observed concomitantly with the lowest average nocturnal IGC (EA, 18 kcal/kg FFM/day; IGC, 98±5mg/dL, athlete C on day 3).

CONCLUSION: Sufficient IGC during night were maintained in male elite triathletes during training camp regardless of EA levels.

EFFECT OF TRAINING ENVIRONMENTS ON GLUCOSE LEVEL VARIABILITY IN ELITE FEMALE ROWERS

MALÁ, M., MILEK, J., STRÍTECKÁ, H., NOVÁKOVÁ, M.

CASRI; DEPARTMENT OF PREVENTIVE MEDICINE, FACULTY OF MEDICINE IN HRADEC KRÁLOVÉ, CHARLES UNIVERSITY

INTRODUCTION: Sports performance is complexly influenced by a variety of factors, including training environments. This pilot study focuses on the analysis of glycemic variability in female elite rowers in the context of three different training environments: regular training, training camp and training in a hypoxic environment. In order to assess the effect of these environments on glycemic variability, the Mean Amplitude of Glucose Excursions (MAGE) values was examined over a four-day follow-up. The aim of this pilot study was to identify differences in glycemic variability across training environments and find out the effect of carbohydrate intake.

METHODS: The sample consists of three experienced female elite rowers (aged 25-28) with a history of glycemic recording. Each athlete underwent four days of monitoring in each training environment. During this time blood glucose level was monitored by using of FreeStyle Libre 2 continuous glucose monitors. Dietary diaries and energy expenditure were also recorded to examine the potential impact of energy balance and diet on glycemic stability. Students paired t-test and descriptive statistics were used to compare MAGE values in each environment.

RESULTS: The statistical analysis showed no significant diference in the mean of MAGE value between regular training condition (1.22 mmol/L ± 0.14) and training camp (1.27 mmol/L ± 0.54), but a significant difference was found between regular training and training conducted at elevated altitudes (1.58 mmol/L ± 0.35 ; $p < 0.01$). Notably, no statistically significant difference was detected across the aforementioned environments in carbohydrate intake (1254 kcal vs. 1105 kcal). However a significant difference ($p < 0.01$) in energy expenditure values emerged between these environmental contexts, with a mean of 3387 kcal during regular training and 2641 kcal during training at higher altitudes.

CONCLUSION: The results suggest that despite similar carbohydrate intake levels between changes in environmental conditions and increased energy expenditure, glycemic variability varies notably. However the precise influence of energy expenditure versus training environment alterations on this variability remains inconclusive and other factors can play a role. Further investigation demands a larger participant pool and higher amount of monitored days to elucidate the nuanced interplay between environmental factors, energy expenditure, and glycemic variability in athletic performance.

PLACEBO EFFECT ON ENDURANCE PERFORMANCE: UNDER-RESEARCHED AND WOMEN FORGOTTEN

VALERO MARTINEZ, F., GONZÁLEZ-MOHÍNO, F., AGUDO-ORTEGA, A., SALINERO, J.J.
UNIVERSIDAD DE CASTILLA LA MANCHA

INTRODUCTION: The potential for enhancing sports performance through the placebo effect has been studied from several perspectives including nutritional and mechanical ergogenic aids (Hurst et al. 2020). Most of the research has been conducted on strength and power-based exercises, while endurance performance has received less attention. However, the occurrence and magnitude of the placebo effect may be affected by sex, although the evidence is limited and sometimes conflicting and these studies have been conducted in medical settings (Enck & Klosterhalfen, 2019; Shafir et al. 2022). The aim of this study was to analyze the existing literature on the placebo effect and endurance sports, with a special focus on the presence of women.

METHODS: The search for published studies on the topic was conducted in the databases Pubmed and Scopus on 10th January 2024. Search terms included Mesh terms and free-text words, for key concepts related to placebo effect and endurance sports. Titles and abstracts were screened for subsequent full-text review. Thirteen studies were selected from the search results based on the following inclusion criteria: inclusion of at least one endurance test and a comparison between a placebo-deceptive condition and a control condition. All studies involved cycling (n=7) or running (n=6) tests and included a total of 229 participants (208 men, 21 women).

RESULTS: Contradictory results were found regarding the effects of placebos on endurance performance. Out of the 13 studies reviewed, 8 reported positive placebo effects. Endurance cycling performance was analyzed in tests from 1 km to 40 km time trial, and 3 out of 7 found a significant placebo effect. Endurance running performance was studied in tests from ≈ 3 to 50 min, where 5 out of 6 found a significant placebo effect. Overall, only 3 studies included women (all were running studies), and no one reported sex-analysis or individual data. In addition, only 9.2% of the total sample were women. The mean sample size in individual studies was 17.6±10.9 participants (median=13) with women comprising only 1.6±3.7 (median=0).

CONCLUSION: There is limited research on endurance performance, with varying test durations, and women are almost excluded.

LONGITUDINAL RELATIONSHIP BETWEEN ORGANISED AND NON-ORGANISED PHYSICAL ACTIVITIES, MOTOR COMPETENCE, AND OVERALL PHYSICAL ACTIVITY IN CHILDREN AGED 3–11 YEARS

LUUKKAINEN, N.M., LAUKKANEN, A., NIEMISTÖ, D., SÄÄKSLAHTI, A.
UNIVERSITY OF JYVÄSKYLÄ

INTRODUCTION

Little is known how different types of physical activity (PA) in early years predict subsequent PA and motor development. This study aimed to find out how outdoor time and participation in sport in early childhood (T1) predicted motor competence (MC) and overall physical activity three years later in school age (T2).

METHODS

The participants (n=627, 51.0% girls) were Finnish, 3-8 years old at T1 (mean 5.5 yrs.), and 6-11 years old at T2 (mean 8.7 yrs.). The participation rate in sports and outdoor time on weekdays and weekends was queried via a parental questionnaire at T1. At T2, children's MC was assessed using a shortened version of the Test of Gross Motor Development – 3rd edition, including locomotor skills (hopping, skipping), and object control skills (one-hand stationary dribbling, overhand throwing), and a total score of these skills. Additionally, the jumping sideways test of the Körperkoordinationstest Für Kinder instrument was used. PA was measured with accelerometers at T2. Associations were analysed using linear regression models with the enter method and interactions using a two-way analysis of variance.

RESULTS

Children's participation in more than two (multisport) organised activities sports at T1 predicted better MC at T2 in locomotor skills ($p < 0.001$), object control skills ($p = 0.003$), total skills ($p < 0.001$), and jumping sideways ($p < 0.001$). Outdoor time on weekdays at T1 predicted better object control skills ($p = 0.004$) and total skills ($p = 0.019$) in all participants. Both higher outdoor time ($p = 0.006$) and participation in multisports ($p = 0.002$) in early childhood predict higher subsequent moderate-to-vigorous PA in middle childhood. However, there were no interactions between organised sports participation and outdoor time on MC or PA.

CONCLUSION

Participation in more than two sports and spending more time outdoors during the weekdays predicted better MC and higher levels of PA. It is essential for adults who work with children and in sports clubs to understand that multisport and different types of outdoor activities play an important role in developing a childs MC and PA.

PERSPECTIVES OF TEACHERS ON (ANTI-) RACISM AND WHITENESS IN PHYSICAL EDUCATION: A (REFLEXIVE) THEMATIC ANALYSIS

ABEL, L., GALLE, A.C., VOGT, T.
GERMAN SPORTS UNIVERSITY COLOGNE

Introduction

Sport, across various social contexts, exhibits inherent racist structures and incidents, impacting children and youth. Physical Education (PE) has the potential to fight racism, yet simultaneously serves as a setting where racist elements may be (re)generated. Given that teachers are central figures in education with a direct impact on students, their experiences and perspectives are extremely valuable in research. The objective of this study was a thematic analysis (TA) of both national (i.e., German) and international (i.e., English language) publications addressing racism and anti-racism within PE with a particular focus on teachers' perspectives.

Methodology

A systematic review adhered to the PRISMA standard and employed a four-step methodology: (1) Search was conducted in eleven electronic databases using twelve keyword combinations in both German and English language. (2) Study selection: Criteria for inclusion comprised (a) peer-reviewed journals, (b) English or German language, (c) participants being pupils, teachers, or researchers, (d) publications addressing (anti-) racism in PE and considering a teachers' perspective. (3) Quality assessment through Appraisal Skills Programme (CASP) and Mixed Methods Appraisal Tool (MMAT). (4) In dept analysis and interpretation of data through reflexive TA and template analysis. Critical Race Theory was utilized as a lance for analysis and discussion.

Results

A total dataset of 5,213 publications was identified of which subsequently 20 (including one German publication) qualified for inclusion. Every publication was assigned to the top quality level out of three using CASP and MMAT. Using TA on the extensive qualitative dataset, four overarching themes were constructed with the two most prominent being (i) "unveiling whiteness", a critical analysis of racial and gender hierarchies in PE that exposes a pervasive dominance of white individuals in roles like educators, students, and faculty members. This asymmetry tends to normalize the experiences of whiteness while marginalizing others, emphasizing the imperative for inclusive narratives in the field. (ii) "Addressing gaps in anti-racist training", which emphasizes a lack of specific courses on race and multiculturalism, with suggestions for integrating such training through pilot projects and reflective learning experiences to raise awareness of race, critical whiteness and tailor interventions to local contexts.

Discussion

Racist experiences of teachers are pervasive in PE, emphasizing the need for structural changes, anti-bias training, and inclusive curricula to address inequalities, male dominance, whiteness and foster diversity in the field.

Given the localized variations in the global phenomenon of racism, it appears crucial to initiate a national survey, to gain insights on developing anti-racism training based on the experience and needs of the intended recipients.

HONG KONG PE TEACHERS' VIEWS ON STUDENTS' MANIFESTATIONS OF MOTIVATION: A QUALITATIVE STUDY

YIP, H.T., LEUNG, K., BALAGUER, I., DUDA, J.
UNIVERSITY OF BIRMINGHAM

INTRODUCTION

Research reveals children and youth in Hong Kong to have low physical activity and physical fitness levels and a high prevalence of obesity. Physical education (PE) in schools can serve as a crucial outlet to promote students' motivation toward and participation in physical activity. However, students are not always optimally engaged in PE, with 2ry school students prone to amotivation. Studies have demonstrated that students motivation in PE is greatly influenced by the views and practices of PE teachers. Past work in this area have primarily adopted quantitative methods and examined students perceptions of their motivation. This study aimed to examine, via an in-depth qualitative methodology, Hong Kong PE teachers' perceptions of the characteristics (thoughts, emotions, and behaviours) of 'motivated' and 'unmotivated' secondary students during PE class.

METHODS

Semi-structured online interviews were conducted with 15 Hong Kong local secondary school PE teachers [n = 7 males; mean age = 34.2 (SD = 9.4); mean years of teaching = 10.7(SD =10.2)] from 3 regions (New Territories, Kowloon and Hong Kong Island) and bandings (grouping students by academic levels or abilities). They were asked to share their experiences and observations in teaching 'motivated' and 'less motivated' 2ry school students in PE classes. The data were analysed using a six-step thematic analysis technique, including creating, reviewing, and defining themes.

RESULTS

Seven themes emerged in the characterisations of 'motivated' students: (a) high proficiency in sports, (b) high interest in sports, (c) higher openness to try (love to engage in new tasks), (d) higher resilience (do the best, never give up, self-assurance), (e) extrovert (outgoing and socially competent), (f) higher relatedness (Give support towards both teachers and peers), and (g) comfortable (experience a sense of ease). Five themes captured teachers' views of 'unmotivated' students: (a) low engagement (frequently seeking means to evade the lesson), (b) unconfident (not willing to try to prevent failure), (c) social exclusion (poor peer relationships), (d) introvert (shy and reticent), and (e) feeling powerless (always fail in doing the tasks).

DISCUSSION

This study is an initial endeavour to qualitatively explore the perspectives of teachers regarding students motivational engagement in PE in Hong Kong. Findings can provide instructors with vital insights to devise effective motivational strategies and create more optimal learning environments in physical education classes in Hong Kong.

THE RELATIONSHIP BETWEEN EMPOWERING MOTIVATIONAL CLIMATE, SELF-DETERMINED MOTIVATION, AND SOCIAL RESPONSIBILITY IN PHYSICAL EDUCATION

DONG FANG, J.D., WANG, C.M., WU, Y.T.

SOOCHOW UNIVERSITY

Introduction

School is a places for education, socializing, and interdisciplinary learning, where teachers and student have interaction. Therefore, studies seek strategies to improve relationships between teacher and students in physical education. Teaching-learning process can assist in personal development and social responsibility. This study attempted to construct a motivational climate model by combining the empowerment motivational climate, self-determined motivation and social responsibility models, with the purpose of verifying the appropriateness of this model.

Methods

The study distributed 450 questionnaire among university students in Taiwan were selected as the sample for the purpose of this study after elimination a total of 410 valid questionnaire was used. A 5-point Likert scale was used in this study, with 5 being the highest agreeable scale and 1 being the least agreeable. The collected survey consist of 157 male and 253 female with age 20.39 ± .This study analyzed using structural equation modeling with CFA to test for reliability and validity and to test the relationship among the variables.

Results

The analysis showed that the measurement model has a good fitness indicator where the $\chi 2/df$ value was smaller than the value of 5, and the RMSEA was at .10 which met the criteria. This study showed that GFIand AGFI was both greater than the value of 0.80. Additionally, the self-determined motivation had the exploratory power of relatedness R2 was .34 giving an exploratory power of 34% and competence R2 was .14 with an exploratory power of 14% and autonomy of R2 was.36 which made up 36% exploratory power. Furthermore, social responsibility showed that helping other R2 was .40 with an exploratory power of 40%, cooperating R2 was .34 with an exploratory power of 34% and leadership R2 was .38 with an exploratory power of 38%.

Discussion

The empowering motivational climate to relatedness showed the highest positive relationship. Moreover, relatedness also showed strong positive relationship toward helping others. All empowering motivational climate had an overal positivel relationship on the self-determined motivation and self-determined motivation also had a positive relation on social responsibility of helping others, cooperating, and leading. In terms of the effect value in the case of a positive overall effect of basic needs on the social responsibility variables of helping others, cooperating, and leading, relatedness showed the overall highest in helping others. Based on the research results, empowerment and self-determined motivation is vital for teaching-learning process for student in physical education, as it can assist in students in self-development and a sense of social responsibility.

A STUDY ON THE PATH TO IMPROVING COLLEGE STUDENTS ECOLOGICAL LITERACY THROUGH OUTDOOR SPORTS ACTIVITIES IN YUNNAN PROVINCE UNDER THE BACKGROUND OF BIODIVERSITY

HUA, X., YANG, X., YIN, G.
YUNNAN UNIVERSITY

Objective: This study aims to investigate the status quo of ecological environment and health literacy among university students in Yunnan Province, as well as to examine the potential impact of participation in outdoor physical activities on the development of ecological environment and health literacy.

Methods: Through questionnaire method, and mathematical and statistical methods, 1681 college students were randomly selected from universities and colleges in Yunnan Province in June-July 2022. Statistical chi-square test and regression analysis were conducted to investigate the participation of college students in outdoor physical activities and the score of a 47-question ecological environmental and health literacy questionnaire based on the "Citizens Environmental and Health Literacy Test Guide (Trial)" issued by Environment Not.

Results: The number of college students in Yunnan Province who had ecological and health literacy (70 points and above) was 493, accounting for 29.35%, and the number of students who did not have ecological and health literacy was 1187, accounting for 70.66%. Among them, 16.6% (279) of college students never participated in outdoor sports activities, 17.74% (298) participated less than once a month, 44.64% (750) participated 1-2 times a month, 9.94% (167) participated 3-4 times a month, and 11.13% (187) participated more than 4 times a month, and the results were analyzed by statistical chi-square test. The results showed that the frequency of outdoor physical activity affecting the ecological environment and health literacy of college students was 1-2 times per month ($X2 = 209.635$, $p<0.05$), 3-4 times per month ($X2 = 43.448$, $p<0.05$), and more than 4 times per month ($X2 = 7.186$, $p<0.05$) with statistically significant differences.

Conclusion: The advancement of ecological civilization is a long-term, sustained process, and the promotion and implementation of ecological and environmental literacy is a crucial aspect of this endeavor. To achieve this, social sports organizations can play a key role in increasing individuals ecological knowledge and raising awareness of the importance of environmental protection. Eco-environmental organizations can leverage their power and influence by conducting environmental protection public welfare activities, providing educational materials, and delivering lectures to college students. Additionally, they can create environmental protection projects and guide college volunteers in carrying out environmental volunteer activities, thus encouraging them to actively participate in and become advocates for ecological protection. Community streets can also utilize social sports organizations to conduct engaging sports activities and promote ecological concepts and policies.

Colleges and universities, as key institutions, should make full use of their role as a primary channel to improve the quality of college students and carry out systematic and planned ecological literacy education. By doing so, university students can enhance their sense of responsibility for nature protection in their daily lives and form an emotional and value identity for environmental protection.

This study has several limitations:(1) The survey conducted in more than 10 universities inevitably suffers from the problem of insufficient coverage and limited representativeness in Yunnan Province. (2) The classification of outdoor physical activities is further subdivided to define the nature of physical activities at a narrow level, which does not fully represent the types of outdoor physical activities and needs to be further validated. (3) There is no way to accurately assess the seriousness of doing the questions in conducting realistic electronic questionnaires, resulting in hierarchical performance results, and more research is needed to continuously improve it.

PREDICTORS OF ATTITUDINAL BELIEFS TOWARDS VIOLENCE IN THE PHYSICAL EDUCATION CONTEXT

BELTRAN-CARRILLO, V.J., JIMÉNEZ-LOAISA, A.2, LEÓN-ZARCEÑO, E.1, JIMÉNEZ-BARBERO, J.A.3, CHILLÓN-GARZÓN, P.4, GONZÁLEZ-CUTRE, D.1
1 MIGUEL HERNÁNDEZ UNIVERSITY OF ELCHE, 2 UNIVERSITY OF CASTILLA-LA MANCHA, 3 UNIVERSITY OF MURCIA, 4 UNIVERSITY OF GRANADA

Introduction

Since school physical education (PE) can be sometimes a site of bullying perpetration (Jiménez-Barbero et al., 2020), to identify the profile of students who tend to be aggressors in PE could be an important step for bullying prevention. The aim of this study was to analyse whether gender, age, physical fitness, sedentary and physical activity level were predictors of attitudinal beliefs towards violence in school.

Methods

A correlational study was carried out with 289 adolescents (152 boys and 137 girls; Mage = 13.98 years, SD = 1.27) from a secondary school located in Elche (Spain). The following variables were measured: Gender and age (sociodemographic questionnaire); aerobic fitness (20 m shuttle run test); strength (hand dynamometer); agility and movement skill (CAMSA test); height and weight to calculate body mass index (BMI); sedentary, light, moderate and vigorous activity (GT3X accelerometers); and attitudinal beliefs towards violence in educational centres (CAHV–25 questionnaire). Two multiple regression analysis were performed, with attitudinal beliefs towards violence as dependent variable, and the rest of variables as predictors. A first model included gender, age, aerobic fitness, strength, agility and movement skill, and BMI as predictors. A second model included the same previous variables as predictors, but adding accelerometer variables.

Results

The first regression was significant (F(6, 282)= 4.065, p < .01, adjusted R2 = 0.060). Boys (β = -.194, p < .01) and students with higher agility and movement skill (β = .143, p < .05) showed higher attitudinal beliefs towards violence.

The second regression was also significant (F(10, 108)= 2.698, p < .01, adjusted R2 = .126). Boys showed more attitudinal beliefs towards violence than girls (β = -.444, p < .001), being higher the effect of gender than in the first regression, but no other significant predictors were found.

Conclusion

Our findings suggest that boys and students with higher agility and movement skill tend to show higher attitudinal belief towards violence. These results are congruent with previous research which had pointed out that skilful boys are the ones who usually tend to harass other students in physical education and school sport (Beltrán-Carrillo et al., 2012). This information could be useful for bullying prevention in these contexts.

PREDICTORS OF BULLYING VICTIMIZATION IN ADOLESCENTS: CONSIDERING THE ROLE OF AGE, GENDER, PHYSICAL FITNESS, AND SEDENTARY AND PHYSICAL ACTIVITY

JIMÉNEZ-LOAISA, A., BELTRÁN-CARRILLO, V.J., GONZÁLEZ-CUTRE, D., VALENCIANO-VALCÁRCEL, J., LEÓN-ZARCEÑO, E.
UNIVERSITY OF CASTILLA-LA MANCHA. MIGUEL HERNÁNDEZ UNIVERSITY OF ELCHE.

Introduction

Bullying victimization is defined as a situation in which a student is frequently and intentionally attacked by one or several students, who are in a position of power in comparison with the victim. Prior research has shown that students who are bullied suffer multiple negative consequences that affect their proper development and well-being (e.g., social isolation, anxiety, lower school performance). Physical education and sports are sensitive spaces where these negative outcomes can worsen, especially during adolescence. However, no previous studies have systematically analyzed the set of variables linked to physical education and sports that could predispose an adolescent to be a victim of bullying. This correlational study addresses this gap. Concretely, we examine the associations between bullying victimization and several variables related to adolescents' age, gender, physical fitness, and sedentary and physical activity.

Methods

A total of 289 adolescents (152 boys and 137 girls; Mage = 13.98 years, SD = 1.28) from a secondary Spanish school completed the Adolescent Peer Relations Instrument (APRI questionnaire) to assess the frequency they experienced bullying victimization. Adolescents also completed several measures to assess their aerobic fitness (multistage 20-meter shuttle run test), strength (manual dynamometer), agility and movement skills (CAMSA test) and body mass index. Sedentary and physical activity were measured with accelerometers. Pearson's correlations were calculated to test the associations among these variables. A hierarchical regression analysis with bullying victimization as dependent variable was also performed. Age, gender (0 = male, 1 = female), and physical fitness were introduced as independent variables in a first model. Physical activity was added in a second model.

Results

Correlation analyses showed that bullying victimization was negatively associated with age (r = -.15, p = .010), aerobic fitness (r = -.17, p = .003), and strength (r = -.15, p = .013), and positively with sedentary activity (r = .26, p = .004). Results of the hierarchical regression analyses showed that the explained variance (adjusted R2) for the second model (.232) was greater than that found in the first model (.051). Specifically, the second model showed that gender (β = -.49, p < .001) and aerobic fitness (β = -.32, p < .01) negatively predicted bullying victimization, and sedentary activity (β = .33, p < .001) positively predicted it.

Conclusion

Bullying victimization could be greater among boys, and in those adolescents with lower aerobic fitness and higher sedentary activity. Physical education and sport educators could consider these findings to promote more respectful and inclusive environments during their interventions. More studies exploring the association between bullying victimization and other "vulnerable characteristics" (e.g., socioeconomic status, sexual orientation, gender identity) are pertinent.

THE EFFECT OF EMPOWERING MOTIVATIONAL CLIMATE, PSYCHOLOGICAL NEEDS ON SELF RESPONSIBILITY

WANG, C.M., LIN, M.S., LU, Y.F.
SOOCHOW UNIVERSITY

Introduction

In recent years' individual responsibility has become a popular topic in sport education, providing students self-responsibility. Universities in Taiwan has a mandatory PE Course of 2 hours per week. Students may complete the four semester pe course during any of their four years in university. Thus, physical education is crucial for students as it can provide psychological and physical benefits. With the use of the empowering motivational climate from Duda et al. (2013), the current study aims to understand the relationship of psychological needs between self-responsibility among physical education students.

Methods

The study consists of 510 University students in Taiwan after elimination of invalid response 501 questionaires were used in the study. This study consist of 210 male and 291 female participants, with an average age of 18.86..The current research recruited to participate in the study, with the use of structural equation modeling with the confirmatory factor analysis (CFA), and the test for reliability to examine consistency and validity including the test of association between the variables.

Results

The analysis showed that Structural equation modeling was implemented to verify the model fit of empowerment motivational, and self-responsibility. The study model validated that relatedness was positively related to respect (β = 0.43 ***); relatedness was positively related to hard word (β = 0.45 ***) relatedness was also positively related to self-direction (β = 0.80 ***).Competence was negatively related to respect (β = -0.12 **); Competence was positively related to hard word (β = 0.2 *); Competence was positively related to self-direction (β = 0.22 **); Moreover, autonomy was was positively related to respect (β = 0.28 **); autonomy was was positively related to hard work (β = 0.24 **);and autonomy was was positively related to self-direction (β = 0.25 **). Discussion

Teachers providing an empowering motivational climate had a positive relationship with self-respect promoting more motivation and reflecting higher self responsibility behaviors. An empowering motivational climate has a positive relationship on hard work. This study establishes a causal relationship between empowering motivational climate, psychological needs, and individual responsibility, it is suggested that teachers, should implement empowering motivational climate in physical education classes, allowing student to feel related is one of the keys to bringing positivity, it can enhance strategies to build an empowering climate, which can meet psychological needs, and promote individual responsibility behaviors.

THE IMPACT OF EXERCISE HEALTH KNOWLEDGE EDUCATION INTERVENTION IN PHYSICAL EDUCATION COURSES ON UNIVERSITY STUDENTS IN THE CONTEMPLATION STAGE OF THE TRANSTHEORETICAL MODEL: EFFECTS ON COGNITIVE PERFO

HSU, K.C.1, WANG, C.A.1, HO, Y.P.2, WEN, H.J.1

1TZU CHI UNIVERSITY, 2NATIONAL TAITUNG UNIVERSITY.

Introduction: The benefits of regular exercise are plentiful; however, individuals with sedentary lifestyles are often advised to begin with exercise health education interventions. This study aims to examine the impact of exercise health knowledge interventions implemented in physical education classes on university students in the contemplation stage. Specifically, we investigate the effects on their cognitive performance in exercise and health, exercise behavior, and levels of physical activity.

Method: The study comprised 33 university students enrolled in mandatory physical education courses who were classified as being in the precontemplation or contemplation stages of the Transtheoretical Model (TTM) of exercise behavior. They were divided into an education group (EG, n=18) and a control group (CG, n=15). The EG underwent a 9-week exercise and health knowledge course utilizing a smartphone-based real-time feedback system, while the CG received conventional skill-based instruction for 2 hours once a week. Both groups completed questionnaires assessing exercise and health cognitive performance, exercise behavior stages, and levels of physical activity in the first week (pre-test) and the tenth week (post-test), comprising 40 items approved by expert scholars. Repeated measures ANOVA were conducted, with significance set at $p \leq 0.05$.

Result: There was a significant interaction effect of time × group ($F(1,31) = 36.45$, $p < 0.001$, $\eta^2 = 0.540$) on exercise and health cognitive performance, along with main effects of time ($F(1,31) = 40.61$, $p < 0.001$, $\eta^2 = 0.567$) and group ($F(1,31) = 9.02$, $p = 0.005$, $\eta^2 = 0.225$). The exercise and health cognitive performance in the EG was significantly better than that in the CG ($p = 0.005$). Furthermore, the EG exhibited a significant improvement within the group in exercise and health cognitive performance (pre: 38.1 ± 3.79 vs. post: 57.89 ± 9.25, $p < 0.01$), while no change was observed in the CG (pre: 39.73 ± 10.98 vs. post: 40.27 ± 10.36). The exercise behavior in the contemplation stages of the Transtheoretical Model (TTM) significantly changed (EG: pre: 1.8 ± 0.4 vs. post: 3.1 ± 1.0; CG: pre: 1.7 ± 0.4 vs. post: 2.4 ± 1.1). Physical activity levels showed no significant change in the EG (pre: 1568.5 ± 276.3 vs. post: 1664.0 ± 511.67 kcal/day) or in the CG (pre: 1760.02 ± 613.48 vs. post: 1653.27 ± 581.51 kcal/day).

Conclusion: The 9-week cognitive intervention did lead to significant improvements in exercise and health cognitive performance and exercise behavior among university students in the precontemplation/contemplation stages of the TTM. While the increase in physical activity did not reach statistical significance, there was a noticeable trend of enhancement. These findings offer valuable insights for experts and educators in physical education, physical activity, and health promotion when formulating policies and arranging physical education curriculum. INVOLVEMENT OF EXPERIENCED ELEMENTARY SCHOOL PHYSICAL EDUCATION TEACHERS WITH COLLEAGUE TEACHERS —FOCUSING ON THINKING IN ADVISING ON LESSON PREPARING —

UMEMURA, T., KAWAMOTO, T., MURAKAMI, M., NAKAJIMA, T.
HOKUSHO UNIVERSITY

INTRODUCTION: Recently, there has been attention to the importance of collaborative training among teachers within schools to enhance physical education classes [1]. While reports on mentoring by senior teachers within the school can be found [2], there is a need for accumulated insights regarding the involvement of experienced teachers with their colleagues within the school.

The purpose of this study was to clarify the thinking of experienced elementary school physical education teachers when interacting with non-specialized colleagues within the school context.

METHODS: The subject of this research was 11 experienced elementary school teachers in physical education classes. We selected teachers with extensive teaching experience and those holding leadership roles in the physical education community as experienced teachers. We conducted semi-structured interviews to investigate teacher's thinking toward the involvement with colleague teachers. The text date of interviews was analyzed by text-mining (KHcoder) in terms of interpretation and outputted a list of frequently occurring terms and a co-occurrence network. We got permission for this research from the principals of each elementary school. Furthermore, we explained to participants about the concept of this research and protecting privacies.

RESULTS: As a result of a text-mining analysis, it would be classified into major categories: "grasp of each child's condition,", "collaboration among teachers,", "the desired image of children to cultivate throughout the unit," and "valuation of positive teaching experiences."

Discussion:

The analysis of interviews revealed that experienced teachers were more conscious of eliciting their colleague teachers intentions and thoughts about teaching when they were planning their physical education lessons. Cooperative conversations between mentors and novice teachers are suggested not only to minimize the isolation of novice teachers during school training but also to connect overall perspectives on childrens learning in both learning theories and practical teaching [3]. Therefore, it was observed that experienced teachers are striving to share the desired image of children while standing on the same perspective as their surrounding colleagues.

ASSESSING THE REPEATABILITY OF A RUNNING HEAT TOLERANCE ASSESSMENT IN TRAINED AND UNTRAINED POPULATIONS.

PALIN, T., SNAPE, D., WOODS, D., WAINWRIGHT, B., STACEY, M., OHARA, J.
LEEDS BECKETT

INTRODUCTION: Increasing hot weather and global temperatures place athletes and outdoor workers at increasing risk of Exertional Heat Illness (EHI). Heat Tolerance Assessment (HTA) has been used in surrogate for future EHI risk, in order to inform decisions on athletic return-to-play and occupational readiness, with protocols often attempting to dichotomise HTA outcomes as pass/fail. However, no international consensus exists in this area of preventative sports medicine. Furthermore, heat tolerance falls on a spectrum that may vary with individual factors including aerobic fitness and heat adaptation (acclimation or acclimatisation). In our experience, concerns arise for fitter individuals, who may pass HTA conducted at relative exercise intensity, but go on to suffer EHI with subsequent exercise-heat stress (i.e. false negative HTA result). We report data concerning metabolic responses to HTA tailored to individual factors in elite, well-trained and recreationally active athletes, and our progress towards better prognosticating EHI risk in the more highly trained.

METHODS: Comprehensive observations of exercising heat tolerance in the elite class of athlete were made before and during a structured laboratory acclimation protocol. Results were used to construct HTA based on the work of Mee et al,(1) with an extension phase of the protocol tailored to lactate thresholds. Two groups of athlete were then recruited from well-trained (WT) and recreationally active (RA) groups. Each participant performed running HTA (30 min at LT1 followed immediately by 30 min at LT2, 1% gradient, 40°C and 40% relative humidity) on two days one week apart (HTA1 and HTA2), without intervening heat adaptation.

RESULTS: Development of the HTA in elite running will be presented. As applied to WT and RA groups, HTA1 vs HTA2 showed no significant differences (P<0.05) at end exercise in core temperature (39.20 ± 0.44°C vs HTA2: 39.13 ± 0.46°C), skin temperature (38.83 ± 0.73°C vs. 38.44 ± 0.73°C), heart rate (181.20 ± 10.76 b·min-1 vs 178.00 ± 10.07 b·min-1), sweat rate (1.46 ± 0.48 kg·hour-1 vs1.25 ± 0.49 kg·hour-1), blood lactate (3.21 ± 1.41mmol·L-1 vs. 3.08 ± 1.34 mmol·L-1) or perceptual scores. Robust agreement between HTA1 and HTA2 was reflected in significant correlations and minimal participant variability on repeatability scoring. Nevertheless, the coefficient of variation was consistently lower for the WT group than the RA group, despite WT achieving significantly higher core body temperature than RA (WT: 39.50 ± 0.00, RA: 38.94 ± 0.42).

CONCLUSION: Our results imply that the HTA is a reliable indicator of physiological and perceptual strain in hot conditions, with increased reliability in fitter individuals. Further work is required to understand its repeatability with heat acclimation and accuracy in predicting recovery from, and future susceptibility to, EHI.

INVESTIGATING THE IMPACT OF MENOPAUSE ON FUEL UTILISATION AND ENERGY EXPENDITURE DURING EXERCISE

RATTLEY, K., DEWHURST, S., FELTON, M., NEAL, R.

BOURNEMOUTH UNIVERSITY

INTRODUCTION: There is a decrease in daily energy expenditure in women during mid-life regardless of menopause stage, but oestrogen deficiency also leads to reduced resting, sleeping, exercise and total energy expenditure. Identifying the deficit in exercise energy expenditure that can be attributed to menopause will aid the development of specific exercise prescription guidance, which may support healthy ageing in and after menopause. This study aimed to evaluate the impact of perimenopause and postmenopause on exercise energy expenditure and respiratory exchange ratio during exercise to maximal intensity.

METHODS: 53 women (PRE: 27 ± 4 yr; PERI: 47 ± 5 yrs; POST: 55 ± 3 yrs; 167.8 ± 5.2 cm, 69.3 ± 9.8 kg), categorised as premenopausal (PRE, n=16), perimenopausal (PERI, n=17) and postmenopausal (POST n=20), completed a maximal aerobic capacity (VO2 max) ramp test on a cycle ergometer, with expired gases measured throughout. Body composition was assessed by bioelectrical impedance. Resting plasma oestradiol, measured by enzyme linked immunosorbent assay (ELISA), was used to confirm menstrual status. Naturally menstruating premenopausal and perimenopausal women were tested during the early follicular phase (1-7 days after starting menstruation), and postmenopausal or hormonal contraceptive users at earliest convenience. Respiratory exchange ratio (RER), energy expenditure, and fat-carbohydrate oxidation crossover point were evaluated between groups using mixed-effects analysis of variance.

RESULTS: Throughout the test, there were differences in energy expenditure between groups (p = 0.02), with the PRE group demonstrating a higher energy expenditure (9.6 ± 3.1 kcal·min-1) than the POST group (8.2 ± 2.7 kcal·min-1) (p<0.05). Body fat mass was different between groups (PRE: 15.6 ± 5.9kg; PERI: 19.8 ± 7.0kg; POST: 22.5 ± 10.1kg, p = 0.05). When normalised for body fat mass, differences in energy expenditure remained (PRE: 0.72 ± 0.22 kcal·min-1·kgBFM; PERI: 0.53 ± 1.9 kcal·min-1·kg·BFM; POST: 0.43 ± 0.14 kcal·min-1·kg·BFM; p<0.01), with PRE energy expenditure greater than POST energy expenditure throughout (p<0.05). There were no differences in the RER (PRE: 0.97 ± 0.13; PERI: 0.96 ± 0.13; POST: 0.96 ± 0.13, p = 0.49) or the exercise intensity at which fat-carbohydrate oxidation crossover occurred between the groups (PRE: 49.6%; PERI: 52.1%, POST: 54.0% of VO2 max, p>0.05).

CONCLUSION: Menstrual status did not impact RER during exercise; this is the first study to evidence that menopause has no effect on RER throughout a maximal exercise test. However, in postmenopause energy expenditure may be limited across all intensities during a maximal exercise test suggesting a ceiling effect potentially linked to increased body fat mass. Further research should evaluate the responses to ecologically valid doses of exercise of women across the lifecycle to better understand the changes that occur and the role of oestrogen deficiency in menopause.

SEX-RELATED DIFFERENCES IN MUSCLE OXYGEN SATURATION IN TRAINED RUNNERS

RODRÍGUEZ-BARBERO EXPÓSITO, S., GONZÁLEZ-RAVÉ, J.M.1, MUÑOZ DE LA CRUZ, V.1, RODRIGO-CARRANZA, V.1, AGUDO-ORTEGA, A.1, SALINERO, J.J.1, GONZÁLEZ-MOHÍNO, F.1,2

1SPORT PERFORMANCE RESEARCH GROUP, FACULTY OF SPORT SCIENCES, UNIVERSITY OF CASTILLA-LA MANCHA, TOLEDO, SPAIN. 2 FACULTAD DE CIENCIAS DE LA VIDA Y DE LA NATURALEZA, UNIVERSIDAD NEBRIJA, MADRID, SPAIN.

INTRODUCTION: Near-infrared spectroscopy (NIRS) is a non-invasive method to measure and evaluate muscle oxygenation in local tissue (1). It is important to note that possible sex-related differences affect the oxygen transport system depending on exercise intensity (2). However, there is a lack of information on possible sex-related differences in muscle oxygenation responses in other exercise modes such as running. Therefore, the present study aimed to analyze possible sex-related differences in muscle oxygen saturation in trained runners.

METHODS: Twelve male and sixteen female trained runners participated in the study. A maximal graded exercise test (GXT) (HP Cosmos Pulsar, HP Cosmos Sports & Medical GMBH, Nussdorf-Traunstein, Germany) was performed. The test started at 8 km·h-1 and 10 km·h-1 for females and males, respectively, and the speed was then increased by 1 km·h-1 every minute until voluntary exhaustion. Two portable NIRS devices (Moxy Monitor) were placed to measure muscle oxygen saturation (SmO2) in the vastus lateralis (VL), at 2/3 of the distance between the line from the anterior spina iliac superior to the lateral side of the patella; and at the most prominent bulge of the medial gastrocnemius (GN). During GTX,

respiratory variables were measured using a gas analyzer (CPX Ultima Series MedGraphics). First (VT1) and second (VT2) ventilatory thresholds and maximal oxygen uptake (VO2max) were identified for each participant. A repeated measures ANOVA was used to compare the differences in SmO2 produced at each threshold with sex as an inter-subject factor.

RESULTS: There were no significant differences in the interaction threshold (VT1, VT2 and VO2max) × sex (men vs. woman) in SmO2. The mean values in SmO2 of VL and GN were significantly lower ($p<0.001$) at VT2 and VO2max in comparison with VT1. Woman presented higher values ($p<0.001$) in SmO2 of VL at VT1 (76.5 vs. 45.5%), VT2 (56.4 vs. 28.0%) and VO2max (41.1 vs. 12.5%) compared to men. The percentage of reduction in SmO2 between VT2 and VO2max were significantly higher ($p<0.004$) in men (56.0 vs. 27.4%) compared to women.

CONCLUSION: The measurement of SmO2 in GN and VL allow to identify a breaking point between the oxygen supply and consumption through NIRS. However, SmO2 had a different behavior in both muscles. Thus, women had higher SmO2 in the three points analyzed in VL but not in GN. Both sexes showed similar patterns of decrease in SmO2 as metabolic demand increases. However, men displayed a strong decline in the VL at VT2 which indicates a better oxygen supply in the active tissues. This fact can be related to a higher muscle vasodilation capacity in females that leads to a redistribution of oxygen to the active tissues and to a higher estrogen concentration.

MODULATION OF ACE2 AND THE MAIN COMPONENTS OF THE RENIN-ANGIOTENSIN SYSTEM IN HUMAN SKELETAL MUSCLE BY BLOOD FLOW RESTRICTION WALKING TRAINING.

GARCIA-GONZALEZ, E.1, THOMPSON, K.M.A.2, GALVAN ALVAREZ, V.1, MARTINEZ-CANTON, M.1, GALLEGO-SELLES, A.1, GARCIA-PEREZ, G.1, MORALES-ALAMO, D.1, SKATTEBO, Ø.3, DE PAZ, J.A.4, BOUSHEL, R.5, HALLEN, J.3, MARTIN-RINCON, M.1, BURR, J.F.2, CALBET, J.A.L.1,3

1 IUIBS AND ULPGC, SPAIN; 2 UNIV. OF GUELPH; 3 NIH, NORWAY; 4 IBIOMED, ULE, SPAIN; 5 SCHOOL OF KINESIOLOGY, UBC, CANADA.

INTRODUCTION: Blood Flow Restriction (BFR) added to any intensity endurance training improves the aerobic capacity of young healthy individuals and trained athletes, likely by acting as a major stressor on fluid regulating systems, as well as on vessel and cardiovascular function. An acute BFR session increases the concentration of blood volume (BV) regulating-hormones such as renin and copeptin, which could be mediated by changes in the main components of the Renin Angiotensin System (RAS). Furthermore, Angiotensin-converting enzyme 2 (ACE2) is a critical modulator of the hyperemic response to exercise and/or BFR. The aim of the study was to assess the changes in maximal aerobic capacity (VO2max) and to determine the effects on basal skeletal muscle (SM) expression of ACE2, its regulatory protein ADAM17 and key components of the RAS elicited by BFR added to walking training in highly trained athletes.

METHODS: Ten highly trained athletes (31.5 ± 5.1yr; 59.2 ± 8.9ml.kg-1, min-1; 7M/3F) were divided into BFR training group (BFR, 100% lowest occlusion pressure) (N=6) and control (CON) (N=4). Both groups performed 6 weeks (3x/week) of 5x3min at 5km/h and 5% incline separated by 1min rest. Resting biopsies were taken from m. vastus lateralis at PRE and POST. Protein expression was measured by WB. Statistics analysis: ANOVA and t-test.

RESULTS: At POST, BFR group showed a significant increase in VO2max (+4.1%, $p=0.017$), that was not present in CON. The protein levels of ACE2 were upregulated in BFR by 25% ($p=0.05$), while remained unchanged in CON (time*group; $p=0.026$). The protein levels of ACE were not modified by training (t-test; $p>0.05$), regardless of group (time*group; $p=0.72$). Similarly, there were no significant changes from PRE to POST for AT1R or AT2R in any groups (t-test; $p>0.05$), with a similar response across groups (time*group; $P>0.31$). The levels of ADAM17 were not significantly reduced by 12.6% in BFR ($p=0.16$), while remained unchanged in CON (time*group; $p=0.26$).

CONCLUSION: This study shows that BFR added to walking improves VO2max and increases the expression levels of ACE2, without apparent changes in other components of the RAS nor ADAM17 in SM of highly trained athletes. We have recently shown a linear association between SM ACE2 and VO2max, which might imply that high levels of ACE2 are present in this population. Nonetheless, data shows that BFR training during walking can be a sufficient stimulus to increase ACE2 in SM, which may facilitate muscle perfusion, oxygen delivery and explain the observed increase in VO2max. Besides a higher ACE2 expression, increasing the conversion of Angiotensin 2 to Angiotensin 1-7 may limit the BV expansion stimulation elicited by activation of the RAS in the context of BFR. It remains to be elucidated what are the effects of BFR training on the expression of ACE2 in less fit individuals and whether it plays role in performance or hemodynamical adaptations.

GENOME-WIDE ASSOCIATION STUDIES IN ELITE JAPANESE ATHLETES

KOZUMA, A., ZEMPO, H.2, SAITO, M.1, HOMMA, H.1, DE ALMEIDA, K.Y.1, DEGUCHI, M.1, MATSUMOTO, S.1, MATSUMOTO, R.3, OKAMOTO, T.1, NAKAZATO, K.1, KIKUCHI, N.1

1 NIPPON SPORT SCIENCE UNIVERSITY, 2 TOKYO SEIEI COLLEGE, 3 IKUEI UNIVERSITY

INTRODUCTION: The heritability of athlete status is estimated at 66% (De Moor et al., 2007). In addition, 253 gene polymorphisms have been reported to be associated with athlete status (Semenova et al., 2023). In this study, we aimed to perform genome-wide association studies (GWAS) in elite Japanese wrestlers to identify novel gene polymorphisms (Study 1) and to replicate the novel gene polymorphisms in another cohort of Japanese wrestlers and elite Japanese weightlifters (Study 2).

METHODS: Study 1 enrolled 41 highly elite wrestlers (35 men and 6 women) who participated in the Olympic games and senior international competitions, and 306 controls (143 men and 163 women). Total DNA was extracted from saliva samples using an Oragene-DNA kit. The subject's gene polymorphisms were genotyped by the Japonica Array v2. This study was a case-control study, with $p < 5\times10^{-8}$ considered statistically significant and the $p < 5\times10^{-5}$ was considered as a suggestive line. Study 2 of the replication cohort included 40 elite wrestlers (31 men and 9 women) from the national competition level and 69 elite weightlifters (38 men and 31 women) from the international competition level (including Olympic games). Targeted controls and genotyping used the same methods as in Study 1. Statistical significance was set at $p < 0.05$.

RESULTS: The GWAS results of Study 1 identified 31 gene polymorphisms that reached $p < 5\times10^{-8}$ and 487 SNPs that reached $p < 5\times10^{-5}$. The identified gene polymorphisms were then divided into 69 regions. The top gene polymorphism was the RBPMS gene rs3116007 polymorphism ($p = 8.67\times10^{-9}$, T allele), located on chromosome 8 and encoding a member of the RNA recognition motif family. Replicated in Study 2, the RBPMS gene rs3116007 polymorphism showed a trend indicating a potential association in elite wrestlers ($p = 0.081$, T allele) and a significant difference in elite weightlifters compared to controls ($p = 0.022$, T allele).

CONCLUSION: Our results identified novel gene polymorphisms associated with high elite Japanese wrestlers. In addition, RBPMS gene rs3116007 polymorphism was similarly trended in elite wrestlers and elite weightlifters.

CONCUSSION-ASSOCIATED GENE VARIANTS AND HISTORY OF CONCUSSION IN ELITE RUGBY ATHLETES.

ANTROBUS, M., BRAZIER, B., CALLUS, P., HERBERT, A., STEBBINGS, G., KHANAL, P., DAY, S., KILDUFF, L., BENNETT, M., ERSKINE, R., RALEIGH, S., COLLINS, M., PITSILADIS, Y., HEFFERNAN, S., WILLIAMS, A.

UNIVERSITY OF NORTHAMPTON

INTRODUCTION: Occurrence of and outcomes following a concussion are probably affected by the interaction of multiple genes in a polygenic manner. This study investigated whether suspected concussion-associated polygenic profiles of elite rugby athletes (RA) with a history of previous concussion differed from RA with no history of previous concussion. We hypothesised that concussion-associated risk genotypes would be underrepresented in RA with no history of concussion compared to RA with a history of previous concussion.

METHODS: Participants were from the RugbyGene project, comprising elite male rugby athletes (141 White males; mean (standard deviation) height 1.86 (0.07) m, mass 102 (12) kg, age 26 (5) yr) competing at an elite level in rugby union (n = 121) and league (n = 20) in the UK, Ireland, Italy and South Africa. Concussion history was collected using a self-reported concussion history questionnaire. PCR of genomic DNA was used to determine genotypes using TaqMan probes, and total genotype scores (TGS) were calculated, then groups were compared using $\chi 2$ and odds ratio (OR) statistics. In addition, multifactor dimensionality reduction (MDR) was used to identify genetic interactions.

RESULTS: Seventy-six percent of rugby athletes reported a history of sustaining at least one concussion and 52% of rugby athletes reported sustaining multiple (≥2) concussions from rugby. For APOE rs405509, the GG genotype was more common in RA with a history of at least one concussion compared to RA with no history of concussion (26.7% vs 12.5%, $P \leq 0.001$, OR = 2.10, 95% CI = 0.58-7.5). The TT genotype of APOE rs405509 was more common (30.8% vs. 26.0% P = 0.036), in rugby athletes with a concussion recovery duration of >10 days (30.8% vs. 26.0%, P = 0.03, OR ≥ 4.14, 95% CI = 1.14-15.06). For COMT rs4680, the AA genotype was more common in RA with history of at least one concussion compared to RA with no history of concussion (37.5% vs 28.3 % OR ≥ 2.10 $P \leq 0.001$, 95% CI = 0.84-10.04). However, TGS did not differ between RA with no previous history of concussion and RA with a previous history of concussion ($p \geq 0.018$).

CONCLUSION: These findings presented support the growing evidence that incidence and recovery from concussion could be influenced by an athlete's genetic predisposition. Such knowledge could be used, in future and when additional relevant variants have been identified, to inform individualised management strategies for athletes in possession of risk genotypes.

TENDON AND LIGAMENT INJURY-ASSOCIATED GENE VARIANTS AND HISTORY OF SOFT TISSUE INJURY IN ELITE RUGBY ATHLETES

BRAZIER, J., ANTROBUS, M.R., RALEIGH, S.M., CULLEN, T., STEBBINGS, G.K., DAY, S.H., HERBERT, A., HEFFERNAN, S.M., CALLUS, P., KILDUFF, L.P., ERSKINE, R.M., WILLIAMS, A.G.

UNIVERISTY OF HERTFORDSHIRE

INTRODUCTION: There is a genetic component to tendon and ligament injuries which is highly likely to be polygenic in nature. Elite rugby has one of the highest reported injury incidences of any professional sport with some of the most severe injuries affecting tendons and ligaments. Thus, this study investigated if suspected tendon and ligament injury-associated polygenic profiles of elite rugby athletes (RA) with a history of prior tendon and ligament injury differed from RA with no history of injury. We hypothesised that tendon and ligament injury-associated genotypes and polygenic profiles would be overrepresented in RA with a history of soft tissue injury compared to RA with no history of injury.

METHODS: Participants from the RugbyGene project were elite white male RA (n = 133; mean (standard deviation) height 1.86 (0.07) m, mass 102 (12) kg, age 26 (5) yr), including 111 rugby union athletes and 22 rugby league athletes. Soft-tissue injury history was collected utilising a self-reported questionnaire. PCR of genomic DNA was used to determine genotypes using TaqMan probes, then groups were compared using X2 and odds ratio (OR) statistics, with alpha set at $P<0.05$. Total genotype scores, SNP-SNP epistasis and inferred haplotypes were used to quantify the combined influence of the polymorphisms.

RESULTS: For COL5A1 rs12722, the CC genotype, proportion of C-allele carriers and C allele were overrepresented in the non-injured ligament group (NIL) (34.3%, 85.9% and 58.6%, respectively) compared to ligament rupture (LR) (19.6%, 66.6% and 43.1%, $P < 0.02$). Furthermore, C-allele carriers were overrepresented, whilst the TT genotype was underrepresented in NIL (86.9% and 17.1%) compared to ligament sprain (LS) (69.8% and 30.2%, $P < 0.02$). NIL had 3.5 times the odds of carrying the CC genotype compared to LR. For MMP3 rs679620, the T allele was overrepresented and C-allele carriers underrepresented in non-injured tendon group (NIT) (23.5%, 44.7% and 76.5%, respectively) compared to the tendinopathy group (TY) (5.7%, 28.6 and 94.3%, $P < 0.03$). Additionally, the C-C inferred haplotype frequency of COL5A1 rs12722 and COL5A1 rs3196378, respectively, was higher in NIL and the all non-injured athlete group compared to LR, LS and the all-injured athlete group ($P < 0.01$). Furthermore, the C-A-G inferred haplotype frequency of MMP3 rs591058, rs650108 and rs679620 was lower in NIT than tendon rupture group ($P < 0.01$).

CONCLUSION: The current data suggest that elite rugby athletes with no history of soft-tissue injury appear to have inherited more resistance to soft tissue injury than their injured peers. The current study provides further insight into the detailed aetiology of musculoskeletal soft tissue injuries within elite rugby and may, in future, be worthy of consideration for managing the interindividual variability of injury risk in rugby.

A GENETIC ASSOCIATION STUDY OF TENDON AND LIGAMENT INJURIES IN ATHLETES: A SYSTEMATIC REVIEW AND META-ANALYSIS

FUKUYAMA, Y., MURAKAMI, H.1, IEMITSU, M.1

1. RITSUMEIKAN UNIVERSITY 2. AINO UNIVERSITY

INTRODUCTION: Athletes train not only for maximum performance, but also to prevent sports injuries. However, athletes cannot avoid sports injuries during intense training and competitions. Among sports injuries, tendon and ligament injuries occur at a rate of 20–30% [1]. In recent studies, one of the intrinsic risk factors that has been identified includes genetic factors that influence the risk of tendon and ligament injuries [2, 3]. Previous studies have not included integrated analyses of multiple genetic factors and tendon and ligament injuries owing to limited sample sizes, differences in athletic competitions, and sex differences. This systematic review and meta-analysis aim to identify the association between gene polymorphisms and tendon and ligament injuries in athletes.

METHODS: A literature search for systematic reviews and meta-analyses was conducted using five databases: PubMed, Web of Science, EBSCO, Cochrane Library, and MEDLINE. All articles were published before July 7, 2023. Eligible articles included genetic studies on tendon and ligament injuries and comparisons between groups of injured and non-injured (control) athletes. Independent reviewers extracted the data. The quality of each article included in the meta-analysis was assessed using the Newcastle-Ottawa Scale (NOS). The odds ratio (OR) and 95% confidence interval (95% CI) were calculated from the sample size of each article. DerSimonian and Laird random-effects model was used, and the heterogeneity between articles was determined using the Q-statistical and I2 test. A $p < 0.05$ was considered statistically significant.

RESULTS: This review comprised 31 articles, comprising 1,687 injuries and 2,227 controls in a meta-analysis of 12 articles. We identified 144 candidate gene polymorphisms, and the meta-analysis included vascular endothelial growth factor A (VEGFA) rs699947, collagen type I alpha 1 rs1800012, collagen type V alpha 1 rs12722, and matrix metalloproteinase 3 rs679620 polymorphisms. The VEGFA rs699947 polymorphism showed a lower risk of injuries in athletes with the C allele ([C vs. A]: OR = 0.80, 95% CI: 0.64–0.99, I2 = 5.0%, p = 0.04). However, the other polymorphisms were not significantly affected. All gene polymorphisms showed no significant publication biases.

CONCLUSION: The VEGFA rs699947 polymorphism is associated with the risk of tendon and ligament injuries in athletes. This result indicates that insights into genetic variations partially contribute to our comprehension of the risk factors for such injuries in athletes.

GENOTYPE SCORE RELATED TO HEPCIDIN REGULATION IS ASSOCIATED WITH IRON STATUS IN JAPANESE MALE ATHLETES

TAKARAGAWA, M., MIYAMOTO-MIKAMI, E., NAGATO, S., NAKAMURA, A., YAMAZAKI, K., FUKU, N.
JUNTENDO UNIVERSITY

INTRODUCTION: Athletes are likely to be more susceptible to iron deficiency and anemia than the general population, due to the fact that they lose more iron as a result of hemolysis and sweating (Rodenberg et al., Corr Sports Med Rep, 2007). Athletes are therefore advised to increase their iron intake. However, factors involved in interindividual differences of intestinal iron absorption have received little attention in general instruction. Iron levels in the body are tightly regulated by hepcidin hormones, which alter the rate of intestinal iron absorption: high levels of hepcidin lead to lower iron absorption, while lower levels of hepcidin lead to higher iron absorption. Previous studies have reported that hepcidin levels are influenced by genetic factors. Therefore, this study examined the association between genetic factors involved in hepcidin regulation and iron status in athletes.

METHODS: A total of 147 Japanese male collegiate track and field athletes were enrolled. These athletes were subjected to a fasting blood draw, a diet and iron supplements survey questionnaire, and saliva collection. Serum ferritin and iron levels were evaluated using latex agglutination turbidimetry and direct colorimetry methods, respectively. Serum hepcidin was measured in duplicate using the Hepcidin-25 ELISA kit according to the protocol provided by the manufacturer. Genetic polymorphisms associated with hepcidin regulation (TMPRSS6 rs855791 T/C, KDM3AP1-SLC40A1 rs12693541 C/T, KDM3AP1-SLC40A1 rs744653 C/T, TFR2 rs7385804, and HFE rs1799945) were analyzed using the TaqMan SNP Genotyping Assay. An individual's genotype score was calculated as follows: a score of 0, 1, and 2 was assigned to each genetic polymorphism, starting with the allele predicted to have high hepcidin levels, from which the total score of the five genetic polymorphisms was calculated.

RESULTS: In linear models, higher genotype scores exhibited a significantly lower hepcidin concentration normalized by ferritin concentration ($R2 = 0.22$, $P = 0.030$). In addition, the higher genotype scores indicated significantly higher serum iron and ferritin concentrations ($R2 = 0.06$, $P = 0.003$ and $R2 = 0.06$, $P = 0.005$, respectively). No significant correlation was observed between the genotype score and the iron or vitamin C intake. The daily iron intake of the athletes was 17.6 g/day, which was more than double the mean iron intake (7.4 g/day) of Japanese general males aged 20-29 years. However, the daily iron intake indicated a significant negative correlation with iron status (serum iron: $r = -0.18$, $P = 0.03$ and ferritin: $r = -0.17$, $P = 0.04$, respectively).

CONCLUSION: Genetic factors involved in hepcidin regulation are associated with iron status in Japanese male collegiate athletes. Our results suggest that genetic information could be used to develop a novel dietary approach that considers iron absorption from the intestinal tract.

SKELETAL MUSCLE GENES ASSOCIATED WITH INFLAMMATION AND INSULIN RESISTANCE ARE INCREASED IN A 'COMPLEX' HUMAN MUSCLE DISUSE MODEL

ALOTHMAN, S., JAMESON, T., KILROE, S., WALL, B., STEPHENS, F.
PRINCESS NOURAH BINT ABDULRAHMAN UNIVERSITY

INTRODUCTION: Human models of muscle disuse are associated with muscle atrophy, insulin resistance of carbohydrate metabolism, and lipid accumulation. However, in practice, muscle disuse is often preceded by injury or trauma causing an inflammatory response. The aim of the present study was to characterize the changes in expression of skeletal muscle genes associated with inflammation and carbohydrate and lipid metabolism in a 'complex' human muscle disuse model that has been preceded by muscle damaging exercise.

METHODS: Twenty-one healthy males (20±1yr, BMI 24±1 kg/m2) completed a 7-day period of knee immobilization that either proceeded by no exercise (CON; n=11) or a bout of 300 bilateral and maximal eccentric muscle contractions (DAM;n=10) immediately before immobilization. At days 0, 2, and 7 muscle biopsies were obtained. Muscle mRNA expression of 12 genes that encode inflammatory proteins known to respond to damaging exercise, and proteins that are rate limiting steps in muscle carbohydrate and lipid metabolism, was determined by Real-Time PCR. Muscle mRNA expression was calculated using the $2^{-\Delta\Delta CT}$ method, with the log2 fold change in mRNA abundance calculated relative to the non-immobilized leg at day 0 for each participant. The study was approved by the Sport and Health Sciences Ethics Committee of the University of Exeter (171206/B/08). Data were analysed using repeated-measure two-factor ANOVA tests (with condition (CON vs. DAM) and time as within-participant factors.

RESULTS: Immobilization increased expression of the inflammation related genes monocyte chemoattractant protein 2 (CCL8), interleukin 18 (IL18), and a tumor necrosis factor alpha receptor (TNFRSF12A) in both groups after 7 days ($P<0.01$), whereas an interleukin 1 receptor (Il1RL1) did not change. Prior eccentric exercise in DAM resulted in greater upregulation of IL18 ($P<0.05$) and TNFRSF12A ($P<0.05$) at day 2. Carbohydrate metabolism associated genes for pyruvate dehydrogenase 4 (PDK4) showed upregulation earlier at day 2 of immobilisation in DAM ($P<0.01$) compared to D7 in CON ($P<0.05$), while both glycogen phosphorylase (PYGM) and lactate dehydrogenase (LDHA) genes were downregulated in response to immobilization similarly in both groups ($P<0.05$). No significant change was observed in hexokinase 2 (HK2) expression. The expression of genes associated with fat oxidation (HADHB, ACAT1, and CPT1B) was decreased ($P<0.05$), and a gene associated with lipid storage (PNPLA2) was increased ($P<0.05$), to a similar degree in both groups after 7 days.

CONCLUSION: Observed changes in genes expression involved in fat and carbohydrate metabolism after immobilisation are consistent with a decrease in oxidation expected with reduced energy demand. Damaging eccentric exercise induced an inflammatory response after 2 days of immobilisation that was associated with a pattern of earlier reduction in carbo-

hydrate (PDK4), but not fat oxidation, suggesting that inflammation may exacerbate the insulin resistance of physical inactivity.

IMPACT OF CHRONIC SLEEP RESTRICTION ON PERFORMANCE AND NEURAL CONTROL OF SUSTAINED CONTRACTIONS: AN EEG-EMG APPROACH

SEYNAEVE, M., MANTINI, D., VANWANSEELE, B., DE BEUKELAAR, T.T.
KU LEUVEN

INTRODUCTION: In modern society insufficient sleep is increasingly prevalent, with one in three adults being chronically sleep-deprived. While the effect of this chronic sleep restriction (CSR) on cognitive functioning is well-established, the effects on motor control remain less clear. Some studies suggest a negative effect of insufficient sleep on tasks requiring higher sensorimotor control, such as balance tasks or submaximal contractions. However, we are still not able to pinpoint the exact underlying neural mechanisms behind this phenomenon. Therefore, this study aimed (i) to examine the effect of CSR on the ability to sustain submaximal plantarflexion (PF) and dorsiflexion (DF) contractions and (ii) to identify the underlying neural mechanisms using high-density electroencephalography (hdEEG) and electromyography (EMG).

METHODS: Using actigraphy, we monitored the sleep pattern of healthy, young male participants for 15 consecutive nights. Motor control was evaluated after four different sleep periods: a baseline period consisting of three nights of habitual sleep (M1), a control period of four nights with normal sleep duration (M2), a period of CSR lasting four nights during which participants slept for only five hours per night (M3), and a recovery sleep period spanning three nights (M4). Motor control assessments consisted of a series of submaximal DF and PF contractions. More specifically, participants performed 6 DF and 6 PF contractions of one minute at 40% of the maximal voluntary contraction (MVC) and 1 submaximal DF and PF contraction until failure. During these contractions, brain activity was measured using hdEEG, and muscle activity of soleus, gastrocnemius, and tibialis anterior muscle using EMG. Complexity and variability of the torque and EMG signals, co-contraction ratios, time until failure, and power in different EEG bands were statistically analyzed using a repeated-measures ANOVA design.

RESULTS: Data is currently being collected and analyzed. We hypothesize that participants ability to resist fatigue will be diminished after the period of CSR. Therefore, markers of fatigue will manifest earlier and to a larger extent. These fatigue markers include (i) a decrease in torque complexity based on detrended fluctuation analysis and entropy measures, (ii) an increase in torque variability, (iii) a decrease in median frequency of the EMG signal, (iv) increased muscle activity co-contraction ratios, (v) decreased time until failure and (vi) increase in EEG power bands. We anticipate that these markers will return to baseline levels following three nights of recovery sleep.

CONCLUSION: A better understanding of the effect of CSR on motor control can offer important insights for clinicians, coaches, and athletes to improve performance, injury prevention programs, and overall health.

MUSCLE ACTIVATION WITHIN HAMSTRING MUSCLES DURING STRENGTHENING EXERCISES: A SYSTEMATIC REVIEW

GUILHEM, G., POIRIER, C., AMEN, X., HEGYI, A., MACCHI, R., GIROUX, C., LACOURPAILLE, L.
FRENCH INSTITUTE OF SPORT

INTRODUCTION: Hamstring muscles play a crucial role in lower limb movement with potential impact on performance, e. g. sprint running [1,2]. The distribution of electromyographic (EMG) activity within hamstrings is highly variable across individuals, influences motor performance and is affected by previous injury [3,4]. Therefore, having an exhaustive understanding of the distribution of muscle activity within hamstring muscles may be particularly useful to design individualized training programs. The aim of the present systematic review was to evaluate hamstring EMG activity during strengthening exercises.

METHODS: Databases used were PubMed, Cochrane Library, and Web of Science with publication date before First January 2023. The references list from the studies included were checked. The search (PICO) strategy selected studies including healthy adults without lower extremity injury, reporting biceps femoris long heads (BFlh) and semitendinosus (ST) activation during hamstring strength exercises. No comparison was considered due to specific cross-sectional study designs. The root mean square (RMS) expressed as a percentage of maximal voluntary isometric contraction and activation ratio (BFlh/ST) were primary outcomes. Nine inclusion criteria and six exclusion criteria were checked by two distinct investigators. Hierarchical ascending classification was applied to cluster strengthening exercises according to BFlh and ST activation.

RESULTS: The search strategy found 302 studies after checking for duplicates. After inclusion screening, 58 studies analysing 23 different exercises were considered. Muscle activations were highly variable across studies, ranging from 5 to 145% for BFlh and 3 to 220% for ST. Hierarchical ascending classification provided 3 different clusters. Cluster 1 exercises included exercises eliciting low activation levels (<40% MVC) preferentially oriented towards BLfh (leg raise, sit-up, leg press, lunge, squat, good morning, kettlebell swing). Cluster 2 included exercises eliciting high activation levels (>80%

MVC) preferentially oriented towards BFlh (sprint, knee curl and leg curl). Custer 3 included exercises with moderate activation levels (40 to 60% MVC) oriented towards ST (sidewise jump, bridge, hip thrust, Sorenssen, Nordic hamstring, unilateral bridge, drop jump, forward jump, hip hinge, cable pulley, deadlift, glider and hip extension).

CONCLUSION: A substantial amount of literature describes medial and lateral hamstring activation across various types of exercises. Significant variability in muscle activation is reported, likely due to differences in movement amplitude, exercise intensity (loading) and posture or execution variations. Independently from these factors, the present systematic review demonstrates that exercise modality can be used to modulate muscle activation in specific muscle heads. These findings can be used by coaches and practitioners to target BFlh or ST for athletic, prevention or rehabilitation purposes.

EFFECTS OF ELECTRICAL MUSCLE STIMULATION AND VOLUNTARY CONTRACTION COMBINED WITH HYPOXIA ON MUSCLE STRENGTH AND NEUROMUSCULAR ACTIVITY

UCHIMARU, J., SON, D.L., SATO, J.

SENDAI UNIVERSITY

INTRODUCTION: Electrical muscle stimulation (EMS) also has been proved to be an alternative method or comparable therapy to traditional strength training by voluntary contractions [1]. Furthermore, both training combined with hypoxia increase muscle strength and induce hypertrophy compere to normoxia [2]. These types of training would be similar effects in skeletal muscle function [3] [4], but the fatigue process and/or muscle fibers' activation seem to be different. Also, hypoxia would be more influence on muscle contractions, muscle fatigue and neuromuscular activations. To our knowledge, there is no research explained why the different mechanisms induce similar effects and what the specific difference is in these exercise modes. We evaluate the effects of voluntary contraction and EMS combined with hypoxia on strength and neuro-muscular activity.

METHODS: Nine healthy and physically active male people participated in this study. Participants completed the four trials; 1) voluntary contraction with normoxia (N-VOL), 2) EMS with normoxia (N-EMS), 3) voluntary contraction with hypoxia (14.5% O2) (H-VOL) and 4) EMS with hypoxia (H-EMS) separated by one-week wash out period. VOL and EMS trial composed of 50 repetitions of 5 seconds tetanic contraction of the thigh. Also, the stimulation intensity with EMS was set to the maximum intensity that they could tolerate. Voluntary contraction was defined as the participants maximum effort. We measured the following measurements before and after trials: knee extent maximal isometric strength (MVC) and EMG activity of rectus femoris muscle (RF), vastus lateralis muscle (VL) and vastus medialis muscle (VM) during tetanic contraction of the thigh, and at 20%, 40%, 60%, 80% and 100%MVC. The root mean square (RMS) and integral electromyogram (iEMG) were analyzed from the EMG data. Additionally, blood lactate concentrations (BLa) were measured before and after trials. Two-way ANOVA with Tukey's test were performed to identify any significant ($P<0.05$).

RESULTS: MVC did not change after each trial. RMS and iEMG at maximum tetanic contraction decreased in N-EMS and increased in H-VOL and H-EMS. RMS and iEMG of VL and VM muscles at submaximal and maximal strength increased (4-10%) after the N-VOL and H-VOL trials. However, N-EMS trial decreased in RMS and iEMG of all muscles, and no change was observed in H-EMS. BLa was significantly increase after H-VOL (from 1.3 to 1.8 mmol/L), N-EMS (from 1.4 to 2.0 mmol/L) and H-EMS trials (from 1.2 to 2.1 mmol/L) ($P<0.05$).

CONCLUSION: From these results, our main findings were as follows: 1) the decrease in EMG activity after EMS may be affected by force production and muscle fatigue with blood lactate accumulation, 2) exercise in a hypoxic environment may induce neuro-muscular activation to maintain force production, regardless of voluntary and involuntary contractions such as EMS.

EXAMINATION OF CHRONOLOGICAL CHANGES IN NEUROMUSCULAR COOPERATIVENESS BEFORE AND AFTER MUSCLE FATIGUE LOADING USING SILENT PERIOD AS AN INDEX.

TAKEMURA, M., KANAMORI, A., MIYAKAWA, S.

リハビリテーション健康科学部学科

INTRODUCTION: It is said that sports injuries are more likely to occur during fatigue. In addition, the function of neuromuscular cooperativeness is important for smooth switching and turning movements that cause sports injuries. The silent period (SP) is a pause in muscular electrical activity observed in a surface electromyography, before a muscular activity is started, leading up to a rapid response movement. The SP contains a pre-motion silent period (PMSP) and a switching silent period (SSP). The SSP is a muscular electrical activity silent period that appears in both the agonist and antagonist muscles, prior to motion when the voluntary movement is performed as quickly as possible. It is defined as the period from the disappearance of muscle discharge in the agonist muscle to the onset of muscle activity in the antagonist muscle. Its appearance mechanism is such that the SP preceding a voluntary movement is thought to involve efferent impulses from the cerebral cortex of the frontal lobe, the cerebellum, and the brain stem repression domain. The period of SSP is also said to be an index that reflects neuromuscular cooperativeness. Therefore, the purpose of this study was to examine chronological changes in neuromuscular cooperativeness before and after muscle fatigue loading using the SP and to examine neuromuscular cooperativeness functions using muscular electrical discharge pauses, or SSP.

METHODS: The chronological changes in neuromuscular cooperativeness before and after muscle fatigue loading of 15 female university athletes (height, 161.8 ± 9.7 cm; weight, 55.2 ± 7.2 kg; age, 20.4 ± 1.4 years) were examined using the indicators of SSP and pre-motor time (PMT) before muscle fatigue loading and immediately after, 5 minutes after, 10 minutes after, and 15 minutes after muscle fatigue loading. The muscle fatigue loading made use of BIODEX (180deg/s),

conducting knee flexion and extension exercises up to a reduction of 50% of maximum muscle strength on one side. This was accompanied by five jump repetitions each on the left and right side before, immediately after, 5 minutes after, 10 minutes after, and 15 minutes after the loading, at which time PMT and SSP were calculated from surface electromyography of the rectus femoris (RF) and the biceps femoris (BF) muscles taken each time.

RESULTS: The results showed no significant differences between the loading side and the non-loading side, and between measurement times, for the RF PMT. However, SSP of the loading side showed significantly prolonged durations for the period immediately following loading and 5 minutes after ($p<0.05$) as compared with the period before loading.

CONCLUSION: These results suggest that fatigue of the knee flexor and extensor muscles immediately decreases neuromuscular coordination during jumping. During muscle fatigue, neuromuscular coordination is impaired and athletes may be more susceptible to injury. The results of this study also show that most of that coordination is restored within 10 minutes.

LATERAL SHUFFLE-INDUCED FATIGUE EFFECTS ON ANKLE PROPRIOCEPTION AND COUNTERMOVEMENT JUMP PERFORMANCE

LYU, M., CHEN, Z., TANG, R., DING, L., DENG, S., ADAMS, R., HAN, J., LI, Y.

1 SCHOOL OF ATHLETIC PERFORMANCE, SHANGHAI UNIVERSITY OF SPORT, SHANGHAI, CHINA; 2 RESEARCH INSTITUTE FOR SPORT AND EXERCISE, UNIVERSITY OF CANBERRA, BRUCE, AUSTRALIA ; 3 COLLEGE OF REHABILITATION S

INTRODUCTION: To determine how lateral shuffle (LS) induced fatigue affects ankle proprioception and countermovement jump (CMJ) performance.

METHODS: Eighteen male college athletes (age: 21.3±1.8 yrs, body mass: 72.8±8.5 kg, height: 177.4±5.8 cm; mean±SD) performed 6 modes of a repeated LS protocol with 2 distances (2.5, 5m) and 3 speeds (1.6, 1.8, and 2.0 m/s) on separated days. The number of change of directions (CODs) in each protocol was recorded. Ankle inversion proprioception (AIP) was measured using the active movement extent discrimination apparatus (AMEDA) after LS. Lower limb neuromuscular performance was evaluated by CMJ. Fatigue measures, including Blood lactate (BLa), rating of perceived exertion (RPE), and heart rate (HR), were assessed before and after LS.

RESULTS: LS-induced fatigue was consistently evident in BLa ($F =23.109$, $p \leq 0.001$, $\eta2= 0.405$), HR ($F =4.575$, $p < 0.05$, $\eta2= 0.119$), and RPE ($F =8.426$, $p \leq 0.001$, $= 0.199$), increasing with shorter distance and faster speed. RM-ANOVA showed a significant distance main effect on both AIP ($F=7.351$, $p < 0.01$, $\eta2= 0.178$) and CMJ ($F=5.265$, $p < 0.05$, $\eta2= 0.134$), but the speed main effect was only significant on CMJ performance ($F =5.265$, $p \leq 0.001$, $\eta2= 0.273$), not AIP scores ($p = 0.87$). While CMJ performance was significantly correlated with Bla, HR and RPE (r range from -0.62 to -0.32, all $p \leq 0.001$), AIP was only correlated with CODs ($r=-0.251$, $p <0.01$).

CONCLUSION: In LS, shorter distance, regardless of speed, was associated with worse AIP, whereas subsequent CMJ performance was affected by both LS distance and speed. Here, AIP performance was not related to physiological fatigue, but CMJ performance was. These results suggest that LS movements affect proprioceptive input and muscular output differently; and that these two aspects of neuromuscular control are affected by physiological fatigue to varying degrees. These findings have implications for injury prevention and performance enhancement.

EFFECT OF SUBMOTOR TIBIAL NERVE STIMULATION ON ANKLE PLANTAR FLEXION IN HEALTHY ADULTS AND ADULT PATIENTS WITH MULTIPLE SCLEROSIS: A PILOT STUDY

MOŠKON, S., ŠINKOVEC, L.1, TOMAŽIN, K.1, AMON, R.2, STROJNIK, V.1, SPUDIC, D.1

1 UNIVERSITY OF LJUBLJANA, FACULTY OF SPORTS, 2 UNIVERSITY CLINICAL CENTRE LJUBLJANA

INTRODUCTION: Multiple sclerosis (MS) is chronic, autoimmune disease expressed with demyelination of neurons of central nervous system (1), resulting in muscular weakness, spasticity and impaired voluntary muscle activation (2). Strength and aerobic training have beneficial effects for managing the symptoms (3), but people with MS often struggle to reach the intended exercise intensity due to decreased voluntary muscle activation. Potential solution is the submotor electrical stimulation (SES), which stimulates sensory neurons, influencing the alpha motor neurons, thereby enhancing voluntary muscle activation (4). The aim of the study was to determine whether SES of the tibial nerve during isometric ankle plantar flexion (PF) affects the produced torque in the ankle, the amplitude and median frequency (MF) of the electromyogram (EMG) of the soleus muscle in healthy adults and adult patients with MS.

METHODS: A pilot study included 10 healthy adults and 10 adult patients with MS. Both groups performed 6 repetitions of PF of the ankle at three different levels (20 %, 60 % and 100 %) of maximal isometric voluntary contraction (MVC) with electrical impulses superimposed on the tibial nerve at frequencies of 20 Hz and 80 Hz (train duration one second). Surface EMG electrodes were applied to the soleus. To observe differences in PF torque, amplitude of the EMG and MF before, during and after SES, three-way ANOVAs were performed separately for each intensity of muscle contraction (20 %, 60 % and 100 %).

RESULTS: Differences in PF torque before, during and after SES were observed (60 %: $p < 0,001$; 100 %: $p < 0,001$). However, contrary to expectations, the PF torque decreased, with a more distinct reduction at 80 Hz SES. MF was found to be dependent on the frequency of SES (20 %: $p < 0,001$; 60 %: $p < 0,001$; 100 %: $p = 0,001$). Generally, the increase of MF was more pronounced during 80 Hz SES. SES did not affect the amplitude of the EMG signal. No differences in the effects of SES on PF torque, MF, or EMG amplitude of the soleus muscle were observed between the groups.

CONCLUSION: The results of the pilot study suggest that SES (1 second, 20 Hz, 80 Hz) has limited potential for acutely increasing ankle PF torque. Most likely and in accordance with previous studies (4, 5), longer SES with higher frequencies would be needed to potentially observe the differences between and within the groups. Due to heterogeneous results in the MS group, further studies are needed to confirm our findings.

VARIATION IN NORDIC HAMSTRING EXERCISE FORCE-ANGLE RELATIONSHIP MEASURES DURING A PROFESSIONAL SENIOR SOCCER SEASON

VAZOUKIS, A., WEAVING, D., WALKER, J., EMMONDS, S.

LEEDS BECKETT UNIVERSITY

INTRODUCTION: Peak eccentric hamstring force is a popular measure during the Nordic hamstring exercise (NHE) to estimate injury risk [1]. However, peak force alone doesn't fully reflect hamstring function during active lengthening. Hamstring injuries are associated with a shift in peak torque at a more flexed knee joint angle [2]. Therefore, examining the full force-angle relationship of the hamstrings can consider the interaction between knee joint angle and force production. This study aimed to construct the force-angle curve of hamstrings during the NHE and quantify the variability of the measures derived from this curve.

METHODS: Twenty-three male soccer players participated from the same English Championship club (age: 27±5 y; stature: 1.83±0.06 m; body mass: 83.2±7.2 kg). A repeated-measures design was conducted during a competitive season whereby force- (NordBord [Vald Performance, Newstead, Australia]) and angle-time (video camera [Sony HXR-NX3/1 NXCAM]) data were collected during the NHE. Force- and angle-time data were synchronised and combined into force-angle profiles. Peak force (N), optimal angle (degrees; deg.), break-point angle (deg; BPA), and eccentric work done (J) were obtained from the force-angle curve of each limb. Players were assessed every 2-5 weeks across the season (8±2 [5 to 12] observations per player). They were instructed to perform the NHE at the slowest pace possible, while the video camera was capturing the movement in the sagittal plane. Data were analysed using mixed-effect models incorporating week as a fixed effect to account for any seasonal trend and player as random effect. Variance permitted to differ across players using a constant variance function structure, enabling estimation of individual standard deviations. Bootstrap resampling was then applied to calculate the overall coefficient of variation (CV; %) and corresponding 90% confidence intervals (CIs).

RESULTS: The overall peak force, optimal angle, BPA, and eccentric work were 476.6±47.7 N, 114.3±6.4 deg,. 121.8±10.1 deg., and 13851±4127 J, respectively. The observed within-player variability expressed as CV (%, 90%CI) was 5.4% (4.4 to 6.4), 5.1% (4.4 to 5.7), 4.6% (4.0 to 5.2), and 17.7% (15.3 to 20.4) for these measures, in order.

CONCLUSION: Peak force, optimal angle, BPA, and eccentric work presented very good (<10%) and good (10-20%) reliability respectively. This approach offers a novel yet reliable method for evaluating hamstring work capacity that extends beyond sole measurement of peak force. Given the nature of hamstring strains and their common occurrence during sprinting, practitioners should incorporate the suggested measures into player monitoring for a better understanding of overall hamstring capacity.

EFFECTS OF REGULAR USE OF POST-EXERCISE INFRARED SAUNA ON DEVELOPMENT OF NEUROMUSCULAR PERFORMANCE AND HYPERTROPHY

AHOKAS, E., HANSTOCK, H.G.2, KYRÖLÄINEN, H.1, IHALAINEN, J.K.1

1> FACULTY OF SPORT AND HEALTH SCIENCES, UNIVERSITY OF JYVÄSKYLÄ, FINLAND; 2> SWEDISH WINTER SPORTS RESEARCH CENTRE, DEPARTMENT OF HEALTH SCIENCES, MID SWEDEN UNIVERSITY, SWEDEN

INTRODUCTION: Long-term exposure to heat has been observed to enhance muscle hypertrophy both in animals (1) and humans (2). Meanwhile, sauna bathing has gained popularity as a post-exercise recovery method among athletes. The aim of this study was to investigate the effects of regular use of an infrared sauna (IRS) after exercise on neuromuscular performance and hypertrophy.

METHODS: A total of 36 female team sport athletes completed the study. The athletes were pair matched into two groups: IRS and control (CON). Physical performance tests and body composition measurements (dual-energy X-ray absorptiometry and ultrasound of m. vastus lateralis) were performed before (PRE) and after (POST) 6-weeks of strength and power training. Performance tests included a 20-m sprint, countermovement jump without extra weight (CMJ) and with extra weight, which were 15%, 25%, and 50% of body weight (CMJ15, CMJ25, and CMJ50), and a maximal isometric leg press (MVC). Participants in the IRS-group used IRS immediately after training three times per week (10 min, 50 °C). A generalized estimating equation (GEE) approach was used to analyze main (group and time) and interaction (time*group) effects. Following the GEE-models, paired and independent t-tests were used to assess main and interaction effects.

RESULTS: There were no time, group, or interaction effects on 20-m sprint time, MVC, or CMJ, CMJ25 and CMJ50. There were group (p=0.002) and time*group interaction effects (p=0.002) for CMJ15 whereby jump height was higher POST-IRS (p=0.006) and PRE-CON (p=0.023) compared to PRE-IRS. There was a time effect (p=0.003) for lean mass which increased in CON (p=0.050). Furthermore, a time effect (p<0.001) was found for lower body lean mass and m. vastus lateralis cross-sectional area (CSA) which increased in both groups (IRS: p=0.002-0.041, CON: p=0.011-0.03).

CONCLUSION: While six weeks of IRS following strength and power training improved performance in CMJ15, no significant improvements were observed in other measures of physical performance following regular IRS use. Consequently, regular IRS bathing after exercise does not appear to have a marked effect on training adaptations in strength and power. Training also improved lower body hypertrophy in female team sport athletes but the regular use of IRS after exercise did not potentiate further hypertrophy.

ASSOCIATION BETWEEN THE RECOVERY OF MUSCLE DAMAGE AND CHANGES IN TORQUE OF MAXIMAL ECCENTRIC EXERCISE

DEGUCHI, M., HOMMA, H., DE ALMEIDA, K., SAITO, M., KOZUMA, A., TSUCHIYA, Y., KOZAKI, K., OCHI, E., OKAMOTO, T., NAKAZATO, K., KIKUCHI, N.

GRADUATE SCHOOL OF NIPPON SPORTS SCIENCE UNIVERSITY

INTRODUCTION: Previously, it has been reported that torque loss immediately after the eccentric exercise reflects the peak of creatin kinase (CK) and other muscle damage response that occurs in the following few days (Nosaka et al., 2006). However, the association between torque changes during eccentric exercise on muscle damage responses at the recovery period, including inflammation response (IL-6, etc.), is unknown. The purpose of present study is to investigate the association between the recovery of muscle damage and changes in torque of maximal eccentric exercise.

METHODS: A total of 95 participants (age: 22.2±2.5 years), including 50 men and 45 women, who had not history of participation in daily resistance exercise of biceps, were enrolled in the study. Participants performed five sets of six maximal eccentric elbow flexion exercises. Maximum voluntary contraction torque (MVC), range of motion (ROM), muscle soreness, serum CK and interleukin-6 (IL-6) concentration were assessed immediately before and after, as well as 1, 2, 3, and 5 days after eccentric exercise. The torque loss (TL2, TL3, TL4, TL5) in sets 2-5 relative to the first set of eccentric exercises was also calculated. Furthermore, deviations were calculated from MVC, ROM, muscle soreness, CK and IL-6 after 5 days of exercise, respectively, and averaged to calculate the Total DV.

RESULTS: Multiple regression analysis using MVC and TL2, 3, 4, 5 immediately after eccentric exercise as a model significantly predicted MVC, ROM, CK, IL-6 and Total DV in the recovery period (after 5 days of exercise) (MVC: 50.3%, ROM: 8.9%, CK: 22.1%, IL-6: 7.9%, Total DV: 32.2%, p<0.05). The predicted probability of each muscle damage response during recovery period was higher than immediately after MVC only (+4.3%, +1.2%, +2.4%, +4.1% and +5.3% respectively compared to MVC only). These results suggest that the assessment of performance changes during exercise may contribute to more accurate prediction of the response at the recovery period.

CONCLUSION: The use of torque loss during exercises in combination with torque loss after the eccentric exercises allowed a more detailed prediction of the recovery process of the muscle damage response.

NEURAL CONTROL OF LEG EXTENSION FORCE IN AN UPRIGHT WEIGHT-BEARING POSTURE AT DIFFERENT KNEE ANGLES

KRÄTSCHMER, R., SCHWIRTZ, A.

TECHNICAL UNIVERSITY OF MUNICH

INTRODUCTION: Assessment of neural control of skeletal muscles is achieved by analyzing motor unit (MU) discharge properties. Typical testing scenarios involve force modulation in non-weight bearing tasks, e.g. isolated knee extension in a seated position. However, humans evolved to stand and move in an upright posture where the leg extending muscles generate force against gravity (1). To address this gap, we devised a setup to measure MU activity during force modulation in different knee angles in an upright weight-bearing scenario.

METHODS: Five participants underwent measurements while standing with both feet on a force plate, with a loaded barbell fixed above their necks, providing immovable resistance. Shin position was standardized to ensure identical ankle angle for all trials. Measurements involved isometric maximal voluntary contractions (MVC) and biofeedback-controlled submaximal force modulation (15 seconds at body weight (BW) followed by 15 seconds at BW+20%MVC) against the immovable barbell in three knee angles (30°, 60°, 90° adjusted by barbell height). High-density EMG signals from vastus lateralis (VL) and vastus medialis (VM) were recorded and decomposed (2,3) into MU discharge rates (DR). Mean DR was calculated for low-threshold (LT, already firing at BW) and high-threshold MUs (HT, start firing above BW). Two-way ANOVA for factors muscle and angle and RM ANOVA for force modulation of LT was performed. Linear regression for relative MVC vs. LT modulation (from BW to BW+20%MVC) was calculated.

RESULTS: While the MVCs increased with a more upright position (90°: 164±51N/kg; 60°: 238±67N/kg; 30°: 341±106N/kg; p<0.001), there was no difference in DR between angles or muscles for LT. At BW+20%MVC, LT showed higher discharge rate than HT (11.90±2.25 and 10.71±2.08pps; p>0.001). During force modulation from BW to BW+20%MVC, LT increased firing rate from 10.06±2.42 to 11.90±2.25pps (p<0.001). There was a significant correlation between relative MVC (averaged across angles) and the difference of DR in LT from low- to high-force (R=0.8630; p=0.0225).

CONCLUSION: As the first study to introduce force modulation in a weight-bearing task, we observed that LT are already firing when bearing own bodyweight, which reveals a functional importance not reflected by isolated non-weight bearing setups. Despite the force differences between angles, the firing rate of MUs at submaximal force did not change indicating that the neural control of VL and VM is regulated independently of muscle length. However, we observed that stronger individuals have a higher ability to increase LT firing rate during force modulation, indicating an association between submaximal neural modulation ability and maximal force generation capacity.

GENDER DIFFERENCES IN PERCEIVED TRAINING STRESS AND THE IMPACT OF MOTIVATIONAL CLIMATE IN COMPETITIVE ATHLETES

RUSNAKOVA, K., HARBICHOVA, I.1, STEHLIK, M.2, KOMARC, M.1

1 FACULTY OF PHYSICAL EDUCATION AND SPORT, CHARLES UNIVERSITY; 2 SPORTS RESEARCH INSTITUTE OF CZECH ARMED FORCES, PRAGUE, CZECH REPUBLIC

Introduction

High training stress is known to precipitate overtraining and performance decline, yet the nuanced impact of gender differences among athletes remain underexplored. The motivational climate created by the coach can contribute to negative psychological outcomes, including stress and overtraining. Understanding gender differences in how athletes perceive training stress and the impact of motivational climate can help in devising more effective strategies. The aim of this study is to investigate gender differences in perceived training stress and examine their relationships with the motivational climate.

Methods

A total of 178 athletes, aged between 18 to 30 years who are actively engaged in competitive sports across diverse disciplines, participated in the online survey. This survey consisted of standardized instruments such as the Training Distress Scale to assess athletes psychological and physical symptoms and the Empowering and Disempowering Motivational Climate Questionnaire-Coach for assessing the athletes perceptions of the motivational environment created by their coach.

Results

Female athletes reported higher levels of training stress compared to male athletes. Specifically, female athletes exhibited elevated scores in 16 out of 19 overtraining symptoms assessed than male athletes. Statistically significant differences were noted in the overall perception of symptoms, particularly in symptoms like "not being able to remember things" and " a quick temper" . Furthermore, an elevated incidence of overtraining symptoms was associated with an ego-involved motivational climate for both genders (female r = 0.25, male r = 0.27). For female athletes, a controlling coaching climate was also associated with a higher prevalence of overtraining symptoms (r = 0.26), highlighting the role of coaching style in athlete well-being.

Discussion

The observed higher incidence of overtraining in female athletes compared to male athletes emphasizes the importance of gender-specific vulnerabilities in the context of overtraining. While the social dimension of overtraining seems to be significant for all elite athletes regardless of gender, the connection between overtraining and a disempowering motivational climate is somewhat more noticeable in female athletes. This association suggests that the nature of the coaching climate, especially aspects that undermine the autonomy and competence of athletes, can disproportionately affect female athletes and contribute to greater training stress. The results of this investigation underscore the need for gender-sensitive approaches in training practices to mitigate the risk of overtraining and optimize the well-being and performance of athletes.

BACK TO COMPETITIVE SPORT

PLESTED-ALVAREZ, M.C.1, ALVAREZ-DUQUE, M.E.2

1.GITT, EDUCATION FACULTY, UNIVERSITY OF ANTIOQUIA, MEDELLIN, COLOMBIA, 2. UNIVERSITY UNAD, MEDELLIN, COLOMBIA

INTRODUCTION: The studied group consisted of 12 female athletes, between 20 and 72 years old, who, before the sports break, were in excellent physical condition and sporting athletic activities; that is, working with maximum weights in the gym or capable of maintaining infernal rhythms in running and various modalities of athletics. The applied analyses gave important results for the conclusions presented, because findings allowed us to ratify a qualitative change in each vision of life. METHODS: Three analytical modalities were applied: interviews with the participants and their coach; the study of group videos as a whole; and twice for each of the participants (at the beginning and end of the six months of training). As well as a bibliographic review of these processes. In all cases, there is informed consent. The corpus studied is made up of some who were high performers and competitive, and others returned to sport to get out of a sedentary lifestyle and recover, as far as possible, adequate sporting ability, according to their age. Also, video records (technique, resistance, and post-training behavior) and interviews as authentic and daily exchange activities were analyzed. RESULTS: In each participant, the difference was auscultated from the decline produced without training, which was greater or lesser in each person (especially if they did not take care of themselves and forgot good maintenance and sustainability practices "at rest"). The latter is understood as the time between the stoppage and the resumption of the sport. The above was compared with the tasks and competencies on the end date of the process. The interviews also took into account specific questions about the state of mind, motivation and prospect of return, because self-appreciation is essential for strengthening ones being. The improvement in the capacity of the various exercises that included the regulated practices was confirmed in the first two months; as well as the training for the initial competitions and the clear improvement in the last two months of this segment of the process of returning to the systematic sporting life of athletics. DISCUSSION: The analysis of behavior, based on gestures, posture, breathing and voice are aspects that set very important guidelines for the specific context and the correlation with the psychosocial mood of each participant. We found that as capacity was gained, joy and euphoria also increased, in some cases; as well as the motivation to continue training in the second half of the year. CONCLUSION: Returning to sport after months or years of being sedentary, especially returning to high-performance athletics, is not an easy task despite having returned to training consistently. The elderly who performed this physical activity were more coordinated. They remembered and recognized the value of the technique. Another advantage of being active again is that their mood improved, because it reduced stress and insomnia.

DOES BASIC PSYCHOLOGICAL NEEDS SATISFACTION DURING THE DAY ENHANCE ATHLETES' SLEEP QUALITY AND REDUCE THEIR SLEEP DEFICIT?

ELBE, A.M., FRYTZ, P.

LEIPZIG UNIVERSITY

Athletes need sufficient restorative sleep to meet the demands of competitive sports. However, due to late competitions, intense training sessions, and dual demands, athletes often experience a sleep deficit (Walsh et al., 2021). Behavioral strategies aimed at enhancing sleep hygiene are frequently employed to reduce this sleep deficit (Bartel et al., 2015). In addition to these strategies, studies indicate that psychological determinants like the satisfaction of basic psychological needs (autonomy, competence, relatedness; Ryan & Deci, 2000) during the day may also improve sleep quality (Campbell et al., 2015).

This study is the first to investigate this relationship in a cohort of competitive athletes (N=48). Thirty-two female and 16 male athletes (M=20.00 years, SD=4.44) from individual and team sports wore actigraphs (Motionwatch 8) for 14 days to measure objective sleep parameters (sleep onset latency, sleep duration, sleep efficiency). Individual sleep deficit and subjective sleep quality were recorded via morning sleep logs. In daily evening logs, athletes reported their basic needs satisfaction, pre-sleep arousal and training load. One-time questionnaires at the beginning of the study also captured general sleep quality (PSQI), chronotype (D-MEQ), and satisfaction of needs in sports (PNSEG) and sleep. Data collection for the study is completed, and the data analysis is ongoing.

Multilevel analysis will determine whether daily basic needs satisfaction has the expected positive impact on athletes sleep quality and reduces their individual sleep deficit. The results aim to unravel the sleep dynamics of athletes and to highlight potential interventions for optimizing athletes sleep.

OPTIMIZING YOUTH ATHLETES WELL-BEING: THE REVOLUTIONARY I7W FRAMEWORK IN SPORTS

HEJLA, M., WILCZYNSKA, D.
GDANSK UNIVERSITY OF PHYSICAL EDUCATION AND SPORT

Introduction

Coaching attitude is a crucial element influencing the development of athletes, shaping their skills, motivation, and attitude towards sports. The i7W model, based on seven principles (inspiration, explanation, expectation, support, reward, appreciation, growth, and winning), is a coaching framework presenting tools that can be utilized in working with athletes. The model focuses on supporting the mental resources of athletes, fostering a positive coach-athlete relationship, and strengthening group cohesion.

Presentation of articles

Workshops for coaches based on the i7W model enhance the experiences and psychological well-being of adult athletes. The latest work on the model also adapts it for working with young sports athletes. Three studies have been conducted so far, examining the effectiveness of training for coaches and its impact on the minds and bodies of young athletes. The research focused particularly on the coach-athlete relationship, sports motivation, anxiety related to sports competition, as well as stress tolerance and motor balance. The studies demonstrated a significant impact of the model on selected psychological factors in children engaged in sports, including motivation and psychomotor performance.

Discussion and future steps

All the tools within the i7W model are mental techniques that a coach can utilize to achieve progress and growth among young athletes. The coachs attitude and coaching environment significantly shape the physical and mental development of young athletes. Implementing the i7W model for coaches results in numerous benefits for young athletes. Further research based on a larger number of coaches and children representing different sports disciplines is necessary.

EXPLORING THE LONGITUDINAL RELATIONSHIPS BETWEEN REGULAR PHYSICAL ACTIVITY, SPORTS, AND WELL-BEING IN YOUTH USING RANDOM FORESTS

WANG, L., LIN, W.
COLLEGE OF LIFE AND ENVIRONMENTAL SCIENCES, UNIVERSITY OF EXETER

ABSTRACT: Well-being is significantly impacting youth developmental trajectory and overall life outcomes which is crucial. Sports, exercise, and physical activity are universally recognized for their beneficial effects on well-being. However, disentangling their individual contributions poses a persistent challenge for researchers. The objective of this study is to employ innovative methods to assess sports and explore the relationship between sports participation, regular physical activity (RPA), and well-being in both cross-sectional and longitudinal studies.

Method: this study utilizes the random forest approach to investigate the intricately interconnected variables of sports and RPA, alongside factors associated with well-being. The assessment of sports, using objective assessment of table tennis skill learning and performance, and subjective assessment of table tennis engagement. The evaluation of RPA, employing a self-reported questionnaire, emphasizing the frequency and duration of moderate to vigorous physical activities (MVPA).

Results: this study encompassed 163 participants, predominantly males (n=133) compared to females (n=30), with an average age of 18.99 years (SD=0.88), The random forest analysis yielded two models with satisfactory fits. The cross-sectional model, which includes baseline sports and regular physical activity, showed a root mean squared error (RMSE) of 14.66 and an R-squared (R^2) value of 0.12. The longitudinal model, examining well-being changes over 8-month period, demonstrated an RMSE of 14.76 and an R^2 of 0.06. Post-adjustment for gender, age, and BMI, the decision tree from Model 1 identified sports and RPA as the most significant factors, accounting for 16.19% of the variance in well-being. Individually, sports accounted for 16.13% of the well-being variance, followed by RPA, which contributed 7.97%. In Model 3, the decision tree similarly highlighted sports and RPA as pivotal, responsible for 16.77% of the well-being variance, with sports alone contributing 13.44% and RPA 7.73%.

Conclusion: this study elucidates that sports have a more substantial correlation with well-being compared to RPA. Moreover, when combining sports with RPA, the correlation with well-being is higher than considering these two factors separately. Future research needs to clarify which aspects of sports participation are more closely associated with well-being. Also, its important to identify which patterns of RPA that most robustly associate with improved well-being.

Discussion: This research is the first to discuss the relationship between sports, RPA, and the well-being of youth using the random forest method. It is also the first study to assess the effects of sports through the evaluation of motor skills, engagement, and performance in sports activities. It suggests that participating in organized sports to develop motor skill, engagement, and performance could be more effective for the well-being of youth than engaging RPA.

ASSOCIATIONS BETWEEN TEST ANXIETY AND PHYSICAL ACTIVITY, SEDENTARY BEHAVIOR, NUTRITION AND SLEEP IN UNIVERSITY STUDENTS

KE, H., DOU, W., LUO, D., CHEN, X., SHI, Y.
BEIJING SPORT UNIVERSITY

INTRODUCTION: Test anxiety is leading to failure or a low academic performance in university students. The sustained low academic performance increases academic pressure and remains considerable physiological and psychological im-

pacts. Consequently, test anxiety is becoming one of the major mental problems among university students. Understanding the relationship between different lifestyle factors and test anxiety is critical to develop intervention strategies and promote students' motivation and academic performance. Therefore, we explored the association between moderate-to-vigorous physical activity (MVPA) time, sedentary time, fruit and vegetable consumption, sleeping time and test anxiety.

METHODS: 138 undergraduate students (mean age = 19.3y, 60.8% females, 39.2% males) participated in this study and completed questionnaires on the week before the formal examination. MVPA, sedentary time and sleeping time were measured via the International Physical Activity Questionnaire (IPAQ). Test anxiety was evaluated by Sarason's test anxiety Scale (TAS). Fruit and vegetables consumption was accessed by Food Frequency Questionnaire (FAQ). Multiple linear regressions were performed to evaluate the associations between MVPA time, sedentary time, fruit and vegetable consumption, sleeping time and test anxiety.

RESULTS: According to the scores of TAS, 84.7% of participants were found to experience moderate to severe test anxiety. A linear regression revealed a negative relationship between physical activity levels and test anxiety levels (r=-0.30, p=0.0003). Similarly, a negative relationship was also detected between vegetables and fruit intake (r=-0.18, p=0.04), sleeping hours (r=-0.20, p=0.02) and test anxiety levels. However, no relationship was observed between sedentary time and test anxiety (r=-0.04, p=0.58).

CONCLUSION: Our results revealed a serious test anxiety problem in university students and negative relationship between test anxiety and physical activity, sleep, fruit and vegetables consumption but no sedentary time. These findings suggest that that sedentary behavior may not contribute to test anxiety. However, healthy lifestyles (enough MVPA, fruit and vegetable consumption and sleeping time) contribute to alleviate test anxiety. Accordingly, our work provides valuable advice for universities to help students overcoming test anxiety.

ANXIETY AND FEAR IN GYMNASTICS: A SYSTEMATIC LITERATURE REVIEW

MALÍR, R., LAROËRE, B.M., CHRUDIMSKÝ, J., CERNÁ, J., TREBICKÝ, V.
FACULTY OF PHYSICAL EDUCATION AND SPORT, CHARLES UNIVERSITY, VAT 00216208

INTRODUCTION: Gymnastics is a highly demanding sport, taxing both physically and mentally. The emotional load during gymnastics events particularly highlights the role of fear and anxiety (1, 2). Although often used interchangeably, some argue that anxiety, unlike fear, arises in response to unknown and vague issues (3). In contrast, fear is a response to a concrete and identifiable danger, such as the fear of failure (4), injury (5), or coach criticism (1). Though experiencing anxiety and fear affects sports performance (3, 6), the literature is mixed on whether they enhance (6) or impair it (7). This study aims to provide a systematic review of current evidence on the role of anxiety and fear in gymnastics.

METHODS: Following the PRISMA 2020 guidelines, we searched scientific article databases (Web of Science, PubMed, EBSCOhost, and Scopus) to identify available full-text peer-reviewed empirical articles in English investigating anxiety and fear in gymnastics. Basic information (authors, year of publication, study design) and details about participants, methods, and results were extracted. The selected studies were assessed for bias after the final selection.

RESULTS: Out of 788 initially collected studies, 39 met the selection criteria after a single round of screening. Predominantly focused on artistic gymnastics (33 studies), the results revealed a higher prevalence of anxiety and fear during competitions compared to training, with no discernible difference in their perceptions across performance levels. Fear of injury, often linked to participants' injury history, emerged as a common cause. However, evidence on how aspects like athletes sex or performance level affect the perception of fear and anxiety remains mixed.

CONCLUSION: Fear and anxiety are frequent concerns in gymnastics, particularly during competitions. However, the available research mainly focuses on artistic gymnastics, leading to insufficient insights into other gymnastic sports. Future research should focus on better distinguishing fear and anxiety and explore more diverse groups of gymnasts.

THE POTENTIAL ROLE OF YOGA FOR DISASTER PREPAREDNESS (BOSAI YOGA)

AKIKO, K.
AOYAMA GAKUIN UNIVERSITY

Mental and physical stress increased by COVID-19, but yoga has been reported to be effective against such stress and to enhance immunity.

To test the hypothesis that yoga enhances human immunity and reduces mental stress in a major infectious disease disaster (COVID-19).

A descriptive questionnaire was administered to 27 Japanese university students aged 19-23 years who practice yoga, regarding the types of stress and the use of yoga in COVID-19.

The results of the questionnaire indicated that stress was caused by restrictions on ones activities, such as not being able to go outside due to fear of corona infection, and anxiety about the lack of relationship building and communication due to the shift to online classes. Many respondents stated that "yoga allowed me to move my body anywhere and anytime without having to go outside, which reduced my physical stress." Others stated that yoga has helped them to notice small changes and discomforts in their own bodies on a regular basis, which has been helpful for the ailments they are currently treating. Many understood that yoga improves metabolism, increases basal body temperature, and boosts immunity. On the mental side, some said that meditation and breathing exercises and improved mental health, and that it not only reduces stress, but also makes one more tolerant of stress afterwards. Some thought that yoga could be used not only for physical and mental health, but also to meet new people through online yoga classes, to reduce friction among family members by practicing yoga with them as a communication tool, and to create a new community. The lack of physical and physical exercise, which prevented them from going out and being physically active due to the fear of coronary infection and the voluntary curfew, contributed to the stress of the survey participants. Many of them were beginners to yoga, but they were willing to embrace yoga as a lifestyle because they realized that yoga could alleviate their lack of exercise under the self-restraint from going out.

Fear of viral infections, decreased physical exercise due to self-restraint, anxiety about relationships and communication due to the shift to online classes, and uncertainty about their adaptation to the new social environment and their future were thought to have physically and mentally repressed them. Yoga postures and breathing techniques have been shown to be effective in relieving such oppression, and the fact that the college students themselves were aware of and understood these benefits indicates that yoga can be used as a tool to overcome various stresses in the future.

The various anxieties brought about by COVID-19, the unprecedented large-scale infectious disease disaster that began in 2020, caused great mental and physical stress for the survey participants, and yoga was thought to reduce such mental stress.

EXERCISE ADDICTION IN ADOLESCENT SAMPLE

JAROCH-LIDZBARSKA, M., WILCZYNSKA, D.

AKADEMIA WYCHOWANIA FIZYCZNEGO I SPORTU W GDAŃSKU

29th Annual ECSS Congress Glasgow/Scotland 2024, July 4-7 2024

Exercise addiction in adolescent sample

Jaroch-Lidzbarska, M., Wilczynska, D.

Gdansk University of Physical Education and Sport

Introduction

Involvement in physical activity provides numerous benefits for both physical and mental health. However the immoderate exercising would have negative consequences, influencing the everyday life, and can lead to the behavioral addiction. The obligatory exercise can exist as primary (driven by motivation associated with dedicated exercise) or secondary problem (with the simultaneous co-occurrence of eating disorders). It is meaningful to check the scale of this phenomenon in the group of adolescents, with special regard to the teenagers diagnosed with eating disorders and those involved in professional sport.

Methods

Ninety individuals in the age range from 14 to 20 (one group of 45 adolescent psychiatric patients diagnosed with eating disorders and 45 teenagers training in the sports sections (15 from track and field, 15 from judo and 15 from the gymnastics section) took part in the study, conducted with an author's online questionnaire. This was a sub-sample from an observational study. The inductive thematic analysis was applied to analyse data. The inclusion and exclusion criteria were defined and scrupulously upheld to ensure trustworthiness of the research.

Results

The leading subjects to investigate in both research groups were: emotions connected with exercises, exercise preoccupation, withdrawal symptoms, need of exercise to control the body mass and problematic eating behaviours among the competitors of each sports section.

Discussion

The findings indicated the preliminary dimension of exercise dependency in Polish adolescent sub-sample. The research process in both groups has varied due to different motivation of the examined youth and, in addition, the environment of research (the psychiatric hospital vs. the coach's office).

The group of respondents with eating disorders demonstrated another attitude to physical activity than the group of adolescent competitors. Both the indicators of the exercise addiction and the problematic eating behaviours diversified among the test subjects from the individual sports sections.

EFFECTS OF COVID-19 PANDEMIC ON ELITE ATHLETES SLEEP BEHAVIOR: A META-ANALYSIS

ZHANG, X., CUI, D.
CAPITAL UNIVERSITY OF PHYSICAL EDUCATION AND SPORTS

Effects of COVID-19 pandemic on elite athletes sleep behavior: A Meta-Analysis

Zhang Xiangning1, Cui Dandan2

1 Capital University of Physical Education and Sports, 2 China Institute of Sport Science

INTRODUCTION: Sleep serves as an indicator of mental health [1], while physical activity is considered to be related to both sleep and mental health [2]. In the early stages of the COVID-19 pandemic, most countries implemented lockdown restrictions [3]. The reduction in physical activity and the secondary psychological issues that arose from the lockdown have significantly affected the sleep quality of elite athletes, ultimately resulting in an indirect impact on their athletic performance. Although a large number of studies have examined the impact of the COVID-19 pandemic on the sleep behavior of individuals at different levels of physical activity, a systematic and targeted evaluation of elite athletes is still lacking. Thus, this meta-analysis aims to assess the influence of the COVID-19 pandemic on the sleep behavior of elite athletes.

METHODS: This meta-analysis was performed by the PRISMA guidelines. A comprehensive search was conducted in online databases including PubMed, Web of Science, and CNKI to detect articles exploring the impact of the COVID-19 pandemic on the sleep behavior of elite athletes. Studies were included if they examined sleep duration among elite athletes without any pre-existing health conditions or no disease risks. In this study, the standardized mean difference (SMD) and the corresponding 95% confidence interval (95% CI) values were pooled using a random effects model. Additionally, a Leave-One-Out sensitivity analysis was performed to ensure the reliability of the results.

RESULTS: A total of nine studies met the criteria with n = 7379 included in this study. The pooled effect showed an increase in sleep duration in elite athletes under lockdown (SMD = -0.56; 95% CI = -0.66 ~ -0.47) and significantly affected by the COVID-19 pandemic ($P < 0.01$), with moderate heterogeneity between results ($I^2 = 69\%$); a decrease in sleep quality (SMD = -0.62; 95%CI =-0.7 ~ -0.54) and significant ($P < 0.01$) with low heterogeneity ($I^2 = 4\%$), and sleep latency was prolonged (SMD = 0.30; 95%CI = 0.13 ~ 0.46) and significant ($P < 0.01$) with moderate heterogeneity ($I^2 = 71\%$). All the results were stable after sensitivity analyses.

CONCLUSION: The COVID-19 pandemic has a significant negative impact on the sleep behavior of elite athletes, which is mainly manifested in the decrease of sleep quality, and an increase in sleep duration and sleep latency of elite athletes. More research on the sleep behavior of elite athletes is needed in the future, supporting decision-making in addressing the challenges posed to the mental health of elite athletes by the ongoing mutation of viruses in current contexts.

THE RELATIONSHIP BETWEEN SCREEN TIME, PHYSICAL ACTIVITY AND MENTAL HEALTH LEVELS IN ADOLESCENTS

DELIANG, X., XINGMEI, Z., ZHANJIA, Z.
PEKING UNIVERSITY, EAST CHINA NORMAL UNIVERSITY

Adolescence is a critical period in human growth, during which the development of mental health plays a key role. It has been demonstrated that physical activity (PA) significantly contributes to mental health (MH) of adolescents by reducing stress, alleviating anxiety, and relieving the depressive symptoms. Moreover, research has also shown that the amount of screen time (ST) influenced MH of adolescents. However, it remains largely unexplored how PA and ST jointly impact MH of adolescents.

purpose: This study aimed to examine the associations between ST, PA and MH in adolescents.

Methods: A cross-sectional study was conducted with 558 middle school students (mean age =13.12, 54.1% females) from 9 provinces in China. Participants were asked to complete questionnaires measuring ST encompassing television, computer, mobile phone, electronic game console, tablet, e-reader, and other screen devices, PA using Physical Activity Questionnaire for Adolescents (PAQ-A), and multiple indicators of MH including the Brief Multidimensional Student Life Satisfaction Scale (BMSLSS-PTPB), Subjective Happiness Scale (SHS), and Kutcher Adolescent Depression Scale (KADS-11). A series of multiple regression models were performed with MH variables as the dependent variable and ST as the predictor. Subsequently, PA was introduced as additional predictor of these models. Gender, age, and maternal education level (MEL) were included in all models as covariates.

Results: ST significantly predicted all MH variables, including life satisfaction ($\beta = -0.114$, $p = 0.02$), subjective happiness ($\beta = -0.137$, $p = 0.01$) and adolescent depression ($\beta = 0.169$, $p < 0.001$). After including PA as additional predictor, ST still significantly predicted MH, but with a reduced level of significance, including life satisfaction ($\beta = -0.086$, $p = 0.08$), subjective happiness ($\beta = -0.102$, $p = 0.03$) and adolescent depression ($\beta = 0.145$, $p = 3.34e-03$). PA was also a significant predictor of all MH variables such that life satisfaction ($\beta = 0.267$, $p < 0.001$), subjective happiness ($\beta = 0.326$, $p < 0.001$) and adolescent depression ($\beta = -0.239$, $p < 0.001$). Regarding covariates, age showed a significant correlation with all MH variables, indicating that higher age is associated with lower life satisfaction ($\beta = -0.101$, $p = 0.04$), lower subjective happiness ($\beta = -0.114$, $p = 0.02$), and higher depression levels ($\beta = 0.108$, $p = 0.03$), while MEL showed a significant correlation with depression ($\beta = -0.126$, $p = 0.01$).

Conclusion: ST and PA Individually influence life satisfaction, subjective happiness, and depression in adolescents with ST having a negative impact and PA having a positive effect. This implies that the regular engagement of PA may act as a protective factor, effectively buffering adolescents against the adverse MH outcomes experienced after screen use. Our findings underscore the suggestion that schools should simultaneously intervene by actively promoting PA and reducing ST to effectively enhance MH.

CP-AP05 Monitoring I

FACTORS INFLUENCING COACHES´ USE OF WEARABLE TECHNOLOGIES FOR INDIVIDUALIZING TRAINING PROCEDURES

DÜKING, P., FORSTER, A., WICKER, P., SPERLICH, B.
TECHNISCHE UNIVERSITÄT BRAUNSCHWEIG

INTRODUCTION: Due to significant inter- and intra-individual variability in response to training, individualization of training procedures is necessary. For this individualization, wearable technologies (wearables) might be supportive in some scenarios, yet it is unknown if coaches use these technologies and what factors affect usage. Based on the Technology Acceptance Model, here we aim to: i) assess the use of wearables and influencing factors of wearables usage among coaches; ii) evaluate the impact of wearables on coaching decisions related to training procedures; and iii) identify factors that could enhance the willingness to use wearables in the context of training individualization.

METHODS: A quantitative online survey which was based around the "Technology Acceptance Model" was conducted among German speaking coaches (n=36, including 15 females) of different performance levels. Questions included i) respondents' socio demographics, ii) current use of, and factors influencing current use of wearable technologies to individualize aspects of training, as well as iii) factors which influence future intention to use wearable technology to individualize training procedures iv) impact of wearables on decision making regarding training procedures. Statistical analysis included correlation analysis including Bonferroni correction

RESULTS: 24 out of 36 coaches use wearables to individualize training procedures. Correlations exist between the current use of wearables with "job relevance" (0.84;$p<0.005$), "subjective norm" (0.57; 0.005), and "perceived usefulness" (0.49;$p<0.005$). Current decisions regarding training procedure only correlate with "output quality" (0.511;$p<0.005$), and "result demonstrability" (0.47;$p<0.005$). Future intention to use wearables to individualize training correlate with "perceived usefulness" (0.644;$p<.005$), "acquire knowledge about sensor technologies" (0.56;$p<0.005$), "result demonstrability" (0.53;$p<0.005$), and "whish for guidelines" (0.50;$p<0.005$).

CONCLUSION: Various factors are associated with the current and future intention to use wearables, as well as their impact on coaches decisions in individualizing training procedures. Our data suggests that it is advisable i) for manufacturers to produce wearables with high output quality and clear demonstrability of results, in order to influence coaching decisions and ii) to equip coaches with comprehensive knowledge and guidelines regarding the use of wearables for the effective individualization of training procedures.

RESEARCH ON THE APPLICATION AND VALUE OF DIGITAL TWIN OPTIMIZATION IN PHYSICAL EDUCATION TEACHING

ZHOU, L., SU, Q., WU, J., LIU, Y.
HARBIN ENGINEERING UNIVERSITY

INTRODUCTION: Digital twins, as a new technology and paradigm, have been applied in large-scale and complex industrial scenarios. It is not just about simple modeling and data collection, but also bi-directional mapping between physical objects in the real world and twins in digital space. Its purpose is to construct a mirror of the real world in virtual space, so as to observe, control, analyze, verify, and deduce at low cost and in multiple dimensions, The physical education teaching scenario is a complex system that requires the application and development of multiple abilities such as physical fitness, skills, thinking, emotions, and intelligence. Exploring the deductive ability of digital twins in analyzing this complex system has theoretical and practical significance.

METHODS: A comprehensive literature review was conducted, collecting papers and industry documents related to the application of digital twin technology in PE and other subject education. An analysis was conducted on the collected data, and a specific university badminton class was used as an example to evaluate the actual implementation ability of digital twins in PE teaching and to determine the current situation, challenges, and solutions of digital twin technology application in PE teaching.

RESULTS: Digital twin technology can adapt to the real-time, dynamic, and interactive characteristics of PE teaching. It can obtain multi-scale and multi-source data through various perception methods, and construct high-precision, high-fidelity, and high-reliability teaching twin scenes. Firstly, high-precision and visual teaching process simulation. It can monitor the present, trace history, and make forward-looking predictions. The second is to improve the quality of teaching and athletic performance. Real-time multimodal data can reflect real-time changes in physical indicators, helping teachers dynamically adjust their training plans. The third is training simulation and prediction. Teachers simulate the whole process of courses in the digital twin world to evaluate the effectiveness of teaching programs and use future data to adjust plans and

emergency drills in advance to improve teaching quality and reduce risks. The fourth is remote monitoring, which simulates game scenes in different environments, to improve its tactical adaptability.

CONCLUSION: Digital twins can provide comprehensive simulation, prediction, and analysis of the PE teaching process from multiple perspectives, improving the efficiency and effectiveness of physical education teaching. However, we still need to address challenges such as technological maturity, data privacy protection, cost, and user acceptance. We should gradually strengthen technological innovation, user education, cost control, and effectiveness verification. By combining digital twins and other emerging technologies, we aim to improve the accessibility and fairness of PE and build an intelligent, universal, and personalized physical education environment.

A COMPARISON OF THE INTERSTITIAL GLUCOSE AND BLOOD GLUCOSE RESPONSES TO CONSUMPTION OF CARBOHYDRATE-CONTAINING BEVERAGES IN HUMANS.

HAMILTON, R., BRACKEN, R.

SWANSEA UNIVERSITY

INTRODUCTION: Continuous Glucose Monitoring (CGM) has gained rapid interest in sports nutrition. CGM measures interstitial glucose as a proxy for blood glucose concentrations. However, consumption of large volumes, high concentration, or high glycaemic index carbohydrate containing solutions may alter the accuracy of the blood to interstitial glucose relationship observed when fasted or post-prandial due to the rapidly changing glucose environments. Thus, this study compared interstitial glucose and blood glucose responses to consumption of carbohydrate-containing beverages in humans.

METHODS: Ten healthy adults (9 males, age 22 ± 1, height 177±12 cm, body mass 75±14 kg) attended the laboratory on seven occasions to consume 0g, 10g & 25g dextrose in 500 ml water, 10% & 20% carbohydrate solutions, and 10% low- (isomaltulose) or 10% high- (dextrose) glycaemic index carbohydrates in a double-blind, randomised, counterbalanced fashion. Capillary blood was collected at rest and over a subsequent 2-h period and analysed for glucose concentration (EKF Diagnostics). Concurrently, interstitial glucose concentrations were recorded (SupersapiensTM, TT1 Products Inc., Atlanta, GA, USA). Glycaemic parameters were compared between both fluid compartments. Mean absolute relative difference (MARD) was determined for periods of hypoglycaemia (<4mM), euglycaemia (4-7.88 mM) and hyperglycaemia (>7.88mM). Plasma volume changes were estimated (Dill & Costill 1974). Data were analysed using ANOVA with Bonferroni correction, and P≤0.05 accepted as significant.

RESULTS: There was a slower time to reach peak glucose concentration in interstitial fluid than blood in 3 of the above carbohydrate consumption trials. Point concentration differences were lower in interstitial fluid than blood in the 25g (iG: 3.47±0.32 vs. BG: 3.75±0.20 mM , P=0.035) and 20% carbohydrate trials (iG: 3.35±0.29 vs. BG: 3.81±0.46 mM, P=0.015). MARD values were 14±16% across all timepoints, 20±28% in hypoglycaemia, 12.2±11.4% in euglycaemia and 14±16% during hyperglycaemia. MARD was greater during hypoglycaemia than during Euglycaemia (p>0.001) and all collective timepoints (p>0.001). Plasma volume changes were similar between carbohydrate trials.

CONCLUSION: These data reveal differences in the interstitial glucose to blood glucose concentrations following carbohydrate beverage consumption. Further, there is a time lag between interstitial and blood glucose concentrations. Finally, mean absolute relative differences were highest in hypoglycaemia. These data suggest caution in the use of continuous glucose monitoring during fast changing glucose environments such as carbohydrate beverage consumption.

Dill DB, & Costill DL. (1974). Calculation of percentage changes in volumes of blood, plasma, and red cells in dehydration. Journal of Applied Physiology, 37(2), 247-248.

AN INITIAL EXPLORATION OF AN INSTRUMENTED MOUTHGUARD TO ESTIMATE HEART RATE

AUSTIN, K., JONES, C.M., LOOSEMORE, M.

UNIVERSITY OF CHICHESTER

INTRODUCTION: Heart rate (HR) monitoring is critical in making informed decisions on training load and recovery prescription [1, 2]. Advancements and miniaturization of sensors have allowed for the monitoring of HR during sports performance, typically at the wrist or chest [3, 4]. There are however multiple sports where these sensors are not permitted, such as combat sports. The inclusion of an LED proximity sensor in some instrumented mouthguards (iMG), typically used for quantifying head impacts in sport, could estimate HR utilising photoplethysmography (PPG). Validation of such sensors is required before performance can be evaluated within combat sports. The aim of this study is to present an initial methodology and evaluate validity for estimating HR through an iMG mounted sensor under controlled conditions.

METHODS: Study methodology was devised in line with the INTERLIVE network recommendations [5]. Four healthy active completed a single laboratory trial of three conditions: five minutes of seated rest, five minutes of low intensity (1.5 W/Kg) and medium intensity (3 W/Kg) cycling (Wattbike, Nottingham, UK). Participants were instrumented with the PROTECHT iMG (Sport and Wellbeing Analytics, Swansea, UK) and a Polar H10 chest strap (Polar Electro, Kempele, Finland) as a gold standard measure [6]. The iMG contains an LED sensor positioned to sit firmly against the gum [7]. The iMG samples at 100Hz and utilizes red light PPG. A novel processing pipeline was devised to accounts for significant baseline noise present within the raw PPG signal. For both methods, the final three minutes of each condition was analysed, with HR averaged over five second intervals. Agreement was assessed using mean absolute percentage error (MAPE; %), root mean square error (RMSE; beats per minute [bpm]) and Lin's concordance correlation coefficient (CCC), with cutoffs of 10% and 0.9 generally accepted for MAPE and CCC, respectively.

RESULTS: Average MAPE was 6.7%, 6.8% and 4.6%, average RMSE was 6.7bpm, 8.1 bpm and 7.5 bpm and average Lin's CCC was 0.93, 0.92 and 0.73 for sitting, low and medium intensity exercise respectively.

CONCLUSION: The initial exploration of an iMG mounted HR sensor found that valid measurements of HR can be obtained from the mouth during sitting and low intensity exercise. Although agreement during medium intensity exercise fell below the pre-determined 0.9 threshold for CCC, average MAPE was the lowest of all conditions and RMSE 7.5 bpm. Although further data is required in sports specific scenarios, findings indicate that sufficient physiological signal can be collected from an iMG, which could allow for HR quantification in sports where traditional sensors are not viable.

GARMIN FÉNIX 7® UNDERESTIMATES PERFORMANCE AT THE LACTATE THRESHOLD IN COMPARISON TO STANDARDIZED BLOOD LACTATE FIELD TEST

SCHLIE, J., HEIBER, M., SCHITTENHELM, A., BECKERT, M., GRAF, P., SCHMIDT, A.

UNIVERSITY OF THE BUNDESWEHR MUNICH

INTRODUCTION: The lactate threshold (LT) is a critical performance measure traditionally obtained using costly laboratory-based tests. Wearables offer a practical and noninvasive alternative for LT assessment in recreational and professional athletes. However, the comparability of these estimates with the regular field tests requires further evaluation.

METHODS: In our sample of 26 participants (nf=7 and nm=19), we compared the estimated running pace and heart rate (HR) at LT with two subsequent tests. First, participants performed the Fenix 7® threshold running test after a calibration phase. Subsequently, they were tested in a standardized, graded blood lactate field test. Age was 25.97 (± 6.26) years, body mass index (BMI) was 24.58 (± 2.8) kg/m2. After the calibration phase, pace and HR at LT were obtained using the Fenix 7® threshold running test. Subsequently, participants underwent a graded blood lactate field test.

RESULTS: Pace at LT calculated by Fenix 7® (M=11.87 km/h ± 1.26 km/h) was 11,8 % lower compared to the field test (M=13.28 km/h ± 1.72 km/h), which was significant ($p < .001$, $d = -1.19$). HR estimated by the Fenix 7® at LT was 1,72 % lower ($p > .05$). LT data obtained in the field test showed greater overall variance.

CONCLUSION: Our results suggest sufficient accuracy of Fenix 7® LT estimates for recreational athletes. It can be assumed that for professional athletes, it would fail to provide the nuanced data needed for high-quality training management.

BALANCE PERFORMANCE OF HEALTHY YOUNG INDIVIDUALS IN REAL VERSUS VIRTUAL ENVIRONMENTS – A SYSTEMATIC REVIEW

SCHEDLER, S., MUEHLBAUER, T.

UNIVERSITY OF DUISBURG-ESSEN

INTRODUCTION: Due to the development of relatively low-cost but high-tech head mounted displays (HMDs), virtual reality (VR) is used more and more frequently in postural control research. However, it remains unclear whether balance performance is affected by for instance the physical characteristics of the hardware used or the application of a virtual visual stimulus. Further, balance performance has been shown to be age-dependent, especially in youth [1]. Therefore, VR may have different effects on balance performance in youth compared to young adults. Thus, the present systematic review aimed to analyse the influence of VR on balance performance in healthy children, adolescents, and young adults.

METHODS: A systematic literature search was performed in the databases of PubMed, Web of Science, and SPORTDiscus. Inclusion criteria were as follows: (i) healthy, young (age ≤ 30 years) participants, (ii) at least one measure of balance had to be tested in the real as well as in a virtual environment, and (iii) the virtual scene was applied using a HMD. To minimize the effect of different VR-scenarios, only studies using a VR environment which resembled the respective real-world condition were included.

RESULTS: A total of nine studies with 171 young adults (19–30 years, 50% females) met the inclusion criteria. Five studies investigated static balance, three studies analysed dynamic balance and one study examined static and dynamic balance performance. Regarding static balance, three studies did not find differences between performances in the real and the virtual scenario, whereas three studies found worse performances under virtual and more challenging (e.g., reduced base of support) conditions. Concerning dynamic balance, three studies reported declined performances in VR compared to the real condition, while one study did not find significant performance differences. No studies investigating children or adolescents met the inclusion criteria.

CONCLUSION: In healthy young adults, declined balance performances under demanding (e.g., reduced base of support) static and dynamic conditions indicate that VR has detrimental effects on postural control, especially when task difficulty increases. Consequently, results from balance assessments in the real world should not be equated with those obtained in VR, even if the VR-scenario resembles the real world surrounding. Future studies should investigate whether balance training difficulty in VR has to be reduced compared to real world training due to decreased balance performance in VR. Additionally, there is a high need for studies on the influence of VR on balance performance in healthy children and adolescents as no such studies met the predefined inclusion criteria.

AN ONTOLOGICAL REASONING-BASED TRAINING RECOMMENDATION SYSTEM FOR TABLE TENNIS AMATEURS

HUANG, W., REN, F.
THE UNIVERSITY OF SYDNEY

INTRODUCTION: The Chinese Table Tennis Association (CTTA) 2023 released the programme "CTTA Table Tennis Sport Level Testing Standards and Guidelines (Trial)", which is divided into four to nine levels, and each testing level can be selected for testing according to their skills, which provides a standardised guideline for professional training to amateur table tennis enthusiasts. This paper develops a table tennis training recommendation system based on the newly released test programme to provide professional training and level assessment goals for amateur table tennis players. This article also uses Ratings of Perceived Exercise (PRE) for subjective fatigue measurement after training to detect the entire training intensity for table tennis enthusiasts in mass sports. In this post, we first presented the system architecture and needs, after which we built a training knowledge base using ontological reasoning. The method was chosen to be used for training and testing by two amateur table tennis enthusiasts who attained a rating standard of level 5 and sought to improve to level 4. The outcomes demonstrated the systems potential as a guiding framework for table tennis aficionados training.

METHODS: The study reported here used a training programme detection system. For this purpose, following the workflow consisting of the collection and processing of the recommended data of not going, first we briefly introduced the use of the system, then we table tennis amateurs first logged into the table tennis recommendation system platform, clicked to enter the platform, the data of this self-testing input, clicked to carry out the recommendation of the training plan to view, you can click to enter the library of material or to the data in the period of The data can be visualised to give better feedback to the amateur table tennis player.

RESULTS: The first and second tests are similar, and the last two tests are very close to passing. If other enthusiasts dont meet the requirements for a tee, you can also use the system to find a fixed partner based on the time that two people attend training sessions together. The results showed that according to the system, there was a difference of 6 points in the final scores between those who trained with the coach and those who trained themselves. According to the self-fatigue tests of two table tennis enthusiasts, it can be seen that at the beginning, the fatigue level was relatively high, and later, they gradually adapted to the training load. This system has certain reference significance for table tennis enthusiasts.

CONCLUSION: This paper focuses on the recently standardized rules that serve as a knowledge base for table tennis enthusiasts searching for professional coaches in popular sports. It also helps to organize and improve the training load for these enthusiasts, provides them with professional and scientific training guidance, and enables real-time monitoring of their training abilities.

TABLE TENNIS PERFORMANCE INDICATORS RELATIONSHIP UNDER FATIGUE CONDITION. A PRELIMINARY ANALYSIS

DELUMEAU, T., PLOT, C., LE CARPENTIER, E., MOUSSEAU, P.
NANTES UNIVERSITÉ

INTRODUCTION: Table tennis player performance has already been defined in the literature by several aspects such as tactics, equipment, and technique. Ball quality of stroke could be one of them, especially ball speed, rotation, or even precision. Few studies have investigated the relationship between those indicators on different stroke conditions and under neuromuscular or mental fatigue which has been proven to be an influential factor in stroke performance. This study aims to observe the effect of fatigue on the relationship between these performance indicators and their evolution in fatigue.

METHODS: Nine young table tennis players men (age :15 ±1.5y; French ranking points: 2103±344) from a French table tennis national centre were selected to perform three experimental trials in a randomized order: a control session, a neuromuscular fatigue session, and a mental fatigue session. Neuromuscular fatigue was induced in biceps brachii. Participants realized ten biceps eccentric contractions with a load of 90% of their 1RM until they reached a 15% loss of their reference MVC. Mental fatigue session consisted of a mentally fatiguing task (90 min AX-CPT test), while the control session required participants to watch a 90 min neutral movie. Each session, athletes had to realize a pre/post table tennis performance test. Players had to perform four exercises using backhand and forehand strokes with backspin and topspin balls. They had to hit thirty balls thrown by a ball launcher. Players must hit the ball cross-court aiming for targets on either side of the table. Ball speed, spin, impact position, and racket acceleration profile were measured during the tests. Subjective feeling of Fatigue and perceived exertion levels were assessed during the sessions.

RESULTS: . Measured RPE and feeling of fatigue were significantly higher post Neuromuscular and Mental fatigue protocols. First results, shows that the ball spin appears to be highly correlated with ball speed ($r=0.96$, $p<0.001$) even under fatigue conditions. Ball speed was also observed slightly correlated with maximum racket acceleration ($r=0.62$, $p<0.001$). Ball speed and spin determine stroke conditions and ranges. Results suggest that forehand topspin produces a fastest ball speed and spin (12 $m{\cdot}s^{-1}$,100 rps to 16.6 $m{\cdot}s^{-1}$, 130 rps) , contrary to the backhand backspin which shows the lowest values (8.33 $m{\cdot}s^{-1}$,60 rps to 10 $m{\cdot}s^{-1}$,80rps). No significant effects of neuromuscular or mental fatigue on group performance were observed, possibly due to individual differences among players.

CONCLUSION: These first results suggest that mental or neuromuscular fatigue was induced with success. Observation of the preliminary results implies that the ball speed /spin relationship seems not affected by the player's fatigue. The determination of the range of speed/spin combination could lead to the design specific of training programs for the players. Further analysis may be needed to conclude properly the effect of fatigue on performance indicators.

DIFFERENCES IN RESPONSE TO A LOW ALTITUDE FOOTBALL TRAINING CAMP SUPPLEMENTED WITH ADDITIONAL HYPOXIC TRAINING

HAMLIN, M., MANIMMANAKORN, A., MANIMMANAKORN, N., SIMPSON, C.

LINCOLN UNIVERSITY

INTRODUCTION: Living and training at altitude is a popular training method for athletes, however, there is considerable individual variation in subsequent sea-level performance improvement where some athletes adapt successfully, while others do not adapt and fail to improve. Since such training is expensive, time consuming, and normally requires considerable logistical planning, coaches and athletes do not want unsuccessful altitude training experiences. Therefore, the aim of this study was to investigate possible physiological measures that might recognise athletes that respond positively to altitude training compared to those that do not.

METHODS: This longitudinal study included 20 male football players (20.6 ± 1.1 years, 173.9 ± 4.8 cm, 67.7 ± 8.3 kg, mean ± SD) who undertook an 8-week training camp at 825 m above sea-level (Khonsan, Chaiyaphum Province, Thailand). Players were also supplemented with intermittent hypoxic training via a hypoxicator (Altitude Training Systems, Australia) 15 min/day 3 times/week at FIO2 of 0.15 while cycling at an exercise intensity between 100-120 W. Based on the players 2800-m running performances between baseline and 14 days post training camp, players were separated into responders (improved by 10.7 ± 8.1%, mean ± 95% CI, n=14) and non-responders (decreased by 6.1 ± 12.8%, n = 6). Changes in the 2800 m run performance along with other physiological variables (resting heart rate, arterial oxygen saturation, heart rate variability, haematology and blood lactate) from the 3 trials (baseline, 1, and 14 days post training camp) and standard deviations representing the between-and within-subject variability were estimated using a mixed modelling procedure (Proc Mixed) in the Statistical Analysis System (Version 9.3, SAS Institute, Cary, North Carolina, USA). The effect size statistic (ES) was also calculated.

RESULTS: Compared to baseline, the responders had a lower heart rate at 1 (-4.6 ± 2.7 bpm, Effect Size = 1.2) and 14 days (-6.7 ± 3.3 bpm, ES = 1.7) post training camp, whereas the non-responders resting heart rate did not change substantially. Compared to the non-responders, the responders had higher pNN50 at 1 (12.2 ± 11.5, p = 0.04, ES = 1.6) and 14 days (10.1 ± 11.7, p = 0.09, ES = 1.4) post training camp. As a result of the training camp, the responders decreased their LF/HF ratio at day 1 (-1.1 ± 0.6, p < 0.01, ES = 1.0) and day 14 post camp (-0.9 ± 0.6, p < 0.01, ES = 0.8), whereas the non-responders LF/HF ratio moved in the opposite direction (0.8 ± 0.9 and 0.9 ± 0.9), with large effect sizes found between groups (ES = 1.7-1.8). Between-group differences in other variables measured were not substantive.

CONCLUSION: Reduced resting heart rate and increased cardiac parasympathetic tone was associated with improved run performance after the altitude training camp and may be used to differentiate athletes that respond to altitude training compared to those that do not.

STUDY ON THE CHANGE RULE OF INTERSTITIAL FLUID GLUCOSE (IFG) IN CYCLISTS DURING TRAINING WITH DIFFERENT LOAD

YU, J., YONG, L.

BEIJING INSTITUTE OF SPORTS SCIENCE

INTRODUCTION: This study aimed to explore the regularity of interstitial fluid glucose (IFG) changes during different load training and the correlation between IFG and training load, to provide new ideas for training monitoring and precise sugar supplementation.

METHODS: 10 male cyclists from Beijing cycling team, with average age of 15.9±0.7 years old, height of 179.08±4.60cm, weight of 69.33±7.54kg, subjected to take part in this study. All of them had more than 2 years of cycling training experience. Continuous glucose monitoring sensor (CGMs) was placed on the back of the upper arm which area has thicker fat and monitored IFG for 14 days. Body composition, Rest metabolic rate (RMR) and maximum oxygen uptake (VO2max) were measured before training sessions (COSMED K5,America and SRM,Germany). During track cycling, road cycling, treadmill training (Rodby 3500, Sweden) and interval high intensity training (Wattbike, England), athletes' heart rate(HR) and IFG were monitored. Athletes began exercise between 1.5-2h after meals and had no sugar intake during training and testing. SPSS 26.0 statistics was applied to analyse data. Repeated-measures ANOVA was used to analyse the results of VO2max and IFG over time with $p < 0.05$ being a significant difference. One-way ANOVA was used to detect the differences of heart rate, RPE and IFG results, with $p<0.05$ being considered a significant difference. All data are expressed as mean±SEM.

RESULTS: The results showed that IFG was significantly correlated with RMR ($p<0.01$). IFG was also significantly correlated with VO2 ($p<0.01$) and VCO2 ($p<0.01$). During the VO2max test, IFG values were obtained by scanning every minute. The average IFG value at 6min, 7min and 8min was significantly higher than that at 1min ($p<0.05$, $p<0.05$, $p<0.05$). Athletes' average IFG during incremental load exercise ranges from 7.6-8.6 mmol/L. The IFG reached its maximum value at the 8th minute and decreased in the following time. Results showed that the average heart rate of high-intensity interval training on wattbike was significantly higher than that of road cycling class ($p< 0.05$). Athletes' RPE after track cycling

and Wattbike training were significantly higher than those of road cycling. The mean value of IFG of track cycling was significantly higher than those of treadmill training, road training and Wattbike training ($p < 0.05$, $p < 0.01$, $p < 0.01$).

CONCLUSION: IFG value is positively correlated with RMR, VO2 and VCO2 in the resting state. IFG could reflect the level of basal energy metabolism of athletes. During exhaustive exercise with increasing load, IFG value increased with time and reached the highest level at an average heart rate 161 rpm, then decreased. The results indicated that IFG changed regularly with training load.It was also found that the average value of IFG in track cycling was the highest, suggesting that this training schedule may stimulate the highest carbohydrate-supplying energy efficiency in the body.

THE EFFECT OF THREE-WEEK MULTIPLE-JOINT EXERCISE COMBINED WITH SELF-EFFICACY THEORY ON SELF-EFFICACY IN OVERWEIGHT/OBESE OLDER ADULTS

KANLAYAWUT, O., KRITPET, T., MAPHONG, R.

CHULALONGKORN UNIVERSITY

The effect of three-week Multiple-joint exercise combined with self-efficacy theory on self-efficacy in obese older adults.

Kanlayawut, O.1, Kritpet, T.2, Maphong, R.3

Faculty of Sports Science, Chulalongkorn University, Bangkok, Thailand

INTRODUCTION: Multiple-joint exercise tends to be more effective in improving a variety of health outcomes across demographics, and self-efficacy theory can increase self-efficacy in older adults. However, the effectiveness of multiple-joint exercise combined with self-efficacy theory on self-efficacy in elderly people with obesity is unknown. This study measured and compared the self-efficacy changes to multiple-joint exercise (MJ) vs. multiple-joint exercise with self-efficacy theory (MJS) in obese older adults.

METHODS: The study included 45 obese seniors (MJ group; n = 22, BMI = 25.65±2.61 kg/m2; MJS group; n = 23, BMI =25.91±3.17 kg/m2) aged 60-75 years. MJ consisted of 8 exercises of 2 sets per exercise alternating with resting 1 minute between sets (MJ 60 minutes/day; exercise 40 minutes, warm-up, and cool-down 10 minutes) for 3 day/week. Self-efficacy theory consisted of four primary source: (a) master experiences: giving knowledge of multi-joint exercise; (b) modeling: 30-minute conversation with a model (c) verbal and compliment: encouraging and complimenting; (d) emotional arousal: giving awards for leaders. The MJ group received MJ only, but MJS group received MJ combined with self-efficacy theory. Self-efficacy was assessed by questionnaire.

RESULTS: Both groups had significantly greater knowledge (pre vs. post; MJS = 5.91±1.8 vs. 8.13±1.3; MJ =6.41±1.3 vs. 7.54±1.7) and self-efficacy for multi-joint exercise knowledge (pre vs. post; MJS = 20.74±3.2 vs. 29.13±1.45; MJ = 21.45±2.0 vs. 28.09±2.2; all $p<0.05$), but no significant differences were observed following the intervention. After receiving the intervention, both groups recognized an increase in personal efficacy following intervention (pre vs. post; MJS = 27.21±3.4 vs. 29.04±1.3; MJ = 27.68±2.3 vs. 27.86±2.0; all $p<0.05$), while the MJS group had a greater expectation (29.04±1.3 vs. 27.86±2).

CONCLUSION: In obese older adults, combining MJ with self-efficacy theory is possible and can be utilized to promote exercise self-efficacy and personal efficacy expectations. Future research is needed to assess the effects of MJS on physical function and blood chemistry in obese elderly people.

ADAPTATION AND SUPPORT METHODS OF CHINESE STUDENT-ATHLETES IN JAPANESE HIGH SCHOOL

LI, Y., NAMIKI, N., HORINO, H.

WASEDA UNIVERSITY

As the globalisation of sports progresses, it is not limited to professional sport. More and more international student-athletes（ISA）are playing sports in other countries. ISA in Japan are mainly concentrated in high schools and universities. While studying at Japanese schools, they compete for their school teams at various levels of competitions to win honours for their school. This paper uses interviews to explore the challenges encountered by Chinese student-athletes（CSA） who have studied in Japan during their high school years. It clarifies their problems in (1) economy, (2) academic, (3) social, (4) competitive, (5) personal emotional and (6)institutional attachment. We also discussed the direction of support for the challenges they encountered. The results of the survey show that CSA in Japan do not receive much pressure in terms of economic and academic pressure in Japan. However, there are greater troubles in socialising, and in managing personal emotions. In addition, CSA indicated that playing sports in Japanese schools is indeed competitive and challenging. However, there are many deficiencies in the rehabilitation and dietary support provided by the school for their injuries and illnesses.Also, because they do not know much about how to enter universities through sport selection in Japan, they do not enter their desired universities after graduation. Therefore, it is important to provide necessary psychological counselling and more timely guidance and assistance to them, and more information on how to enter universities after graduation.

THE EFFECT OF EXERCISE ON IDEAL SELF, EXPECTANCY VALUE AND PURCHASE INTENTION OF APPLE WATCH

WU, Y.T.
SOOCHOW UNIVERSITY

Introduction

Self-concept is linked to an individual's assessment of goods and services. Where the evaluation of products through themselves when using the product can be described as the self-congruence theory. This study attempts to understand consumers value when considering the smart wearable product with cognitively dominated attitude and intention theory model. Therefore, this study focuses on identifying the expectancy-value model (EVM) of attitude to adequately capture the effect of expected value toward the Apple Watch.

Methods

The current research consists of 350 participants recruited to participate in the study, after elimination of invalid questionnaire 325 questionnaires were used Firstly, questionnaires need back and forth translation from English to Traditional Chinese. Secondly, structural equation modeling was used to stipulate the phenomenon of the reason and consequence variables with the confirmatory factor analysis (CFA) using partial least square analysis. Lastly, reliability was tested to examine consistency and validity including the test of association between the variables. Results

The study consisted of 150 female participant 46.3%, and 174 male participants 53.7% from Taiwan who exercise at least once a week.. A good model fit was accepted with confirmatory fit index CFI >.9 was at .89, Tucker& Lewis index TLI >.9 was at .875. The squared multiple correlation was .10 for hedonic value and .12 for utilitarian value accounting for 10% and 12% of ideal self. Moreover, behavior intention was seen with .47 which is 47% variance accounted by hedonic value and utilitarian value. The study found positive relationship of ideal self and hedonic value b=.313: and positive relationship of ideal self and utilitarian value.345. Hedonic value and utilitarian both showed positive relationship for behavior intention b=.369; b=.538. Discussion

This study showed ideal self has a positive relationship with hedonic value as its emphases on the appealing characteristics of a product and produces desire, on the other hand ideal self also showed a positive relationship on the utilitarian value since the basics of utilitarian values consist of task related, and rational decision making. Hedonic value and utilitarian value have their differences in value, where one is personal value such as fun and playfulness and the other is more of completion of goal. According to the values this study focuses on the relationship it has of hedonic and utilitarian value toward the the behavior intention of buying a apple watch which all showed positive relationship between the variables.

IMPLICIT MOTIVES IN PROFESSIONAL FOOTBALL AND THEIR CONCLUDED NEEDS FOR COACHING PROCESSES

SPRECKELS, C.
UNIVERSITY OF HAMBURG

Introduction

Investigation showed that not only talent (Kang et al 2015) but certain personality traits could be predictive for a successful sports career (Kazén & Quirin 2018). As shown in other investigations confidence in success or fear of failure could be seen as states and not traits (Kazén, Kuhl & Quirin 2015). According to the Personality System Interaction Theory (PSI, Kuhl 2001) to hit the implicit motives support the confidence in success. Aim of this study was to explore if implicit motives of professional football players differ from the normal population and if certain clubs differ from others, so that it would a big point to coach them due to their individual personality. It also could be an explanation why certain coaches are successful within a certain club and others are not, because besides their football expertise their personality is matching.

Methods

N= 207 footballplayer of five clubs of the first and second league in Germany, aged 25 ± 7 years, were tested with the implicit personality test ViQ. This test includes the four main characters (worker, teamplayer, creative and dominant) as well as four motivational factors, which sums up to 16 different types. Comparing with the normal population of a mass media example (N= 24.000) and within different clubs the null hypothesis was, that the footballplayers don't differ from normal population and within different clubs and the hypothesis according to this is that they differ. The chi^2-Test was used for calculation.

Results

Results show that there is no significant difference from normal population to professional football players in the worker type ST (p=0,185) but differences in the three other types, TeamplayerType SF, Creative Type NF and Dominant Type NT, all significant (p<0,005). Differences between Clubs are also significant (p<0,005) within certain personality dimensions due to the PSI-Theory (Kuhl 2001).

Conclusions

Soccer coaches with their own combination of implicit motives should consider that their players may have different motives than other players in other clubs and themselves in order to be able to motivate them well, because the explicit motives have a directing effect and the implicit ones have an energizing effect, which determine the degree of motivation. Furthermore, it should be noted that this differs between clubs due to a specific club culture.

INVESTIGATING YOUTH PLAYERS PERFORMANCE UNDER COACH-CREATED MOTIVATIONAL CLIMATES IN HONG KONG: AN EMPOWERING COACHING THEORY PERSPECTIVE

CARMAN LEUNG, K.M., DUDA, J.L., SHI, Y., YIP, H.D.

THE EDUCATION UNIVERSITY OF HONG KONG

Introduction

Motivational climates are arguably to generate diverse outcomes in terms of youth players' psychological states as well as actual behaviors during sport participations. These outcomes can be explained by the theory of empowering coaching, reflecting the coach-created motivational climates which are characterized as either empowering or disempowering (Duda et al., 2017). To date, limited studies have examined the perceptions of Hong Kong sport coaches regarding the coaching environments they created. The present study aimed to examine perceptions of coaches regarding motivational climates, specifically what they witness of their players' participation attitudes and behaviors under empowering or disempowering climates and what elements can be associated with motivated and demotivated themes.

Methods

A semi-structured interview guide based on the Empowering Coaching Theory of Duda et al. (2017) was designed for adaptation to the local context. A total of 30 coaches with an age range from 19 to 63 years old (M=35.5; SD=11.94) were recruited. They were stratified by sex (50% male and 50% female) and coaching experience (60% with over six years and 33.3% with less than five years of coaching experience). Coaches were asked to recall their experience in carrying out specific coaching strategies that they thought were effective or ineffective in motivating young players, as well as young sport participants' attitudes and behaviors that they have coached during the training and competition. A six-step thematic analysis procedure was performed to process the data.

Results

With respect to the motivation and experiences of youth players during sport participation, eight themes were identified, namely (a) hunger to achieve more, (b) commitment, (c) team cohesion, (d) expectations regarding excellence, (e) lifelong progression were recognized as optimally motivated attributes reflecting an empowering climate, while (f) passive coping, (g) fear of being a liability, and (h) discouragement from further development were recognized as demotivated attributes reflecting a disempowering climate.

Discussion

The results revealed that players who were motivated and had experience in empowering climates exhibited empowered characteristics, including autonomy support, task involvement, and social support, whereas the attitudes and behaviors of demotivated players tended to exhibit psychological need thwarting features, such as ego involvement and controlling behaviors. This study embraces the Empowering Coaching Theory as the theoretical framework to produce contributions to the theoretical literature, which extends our understanding of the attributes that can reflect specific coach-created motivational climates.

and less disempowering environments in youth sport: Theory to evidenced-based practice. In Sport psychology for young athletes (pp. 81-93). Routledge.

EFFECTS OF SIDE-BY-SIDE PARTNER ON ENJOYMENT AND MOTIVATION IN HIGH-PACED TREADMILL RUNNING

HOSHINO, S., NARUSE, Y., HAMAURA, M., ARAUCHI, K., KOMORI, Y.

NARA WOMENS UNIVERSITY

INTRODUCTION

The phenomenon in which performance is improved by the presence of others is called social facilitation (Zajonc, 1965). For runners the interaction with running partner influences the appeal to run. We reported the importance of running partner regarding their enjoyment with a comfortable self-paced running (Hoshino et al, 2023). A theoretical approach that has shown evidence of how motivational factors can support enjoyment of a physical activity is self-determination theory (SDT) (Deci and Ryan, 1985). According to SDT, we investigated how different elements of "autonomy", "competence", and "relatedness" are influenced a running with the presence of a partner during high intensity running.

METHOD

Subjects: 14 female university and graduate students (20.9 ± 1.6 yr.) .

Tasks and conditions: Flat treadmill self-paced running for 30 minutes under two conditions (1) Solo condition (SC): running alone and (2) Partner condition (PC): running side by side with a partner. In both conditions, subjects were instructed to

"run as far as you can in 30 minutes. The rate of increase/decrease from the initial speed (each subjects lactate threshold) was presented as the feedback information on the screen.

Measurements: (a) Behavioral indices: total running distance, running speed, and rate of speed increase every 5 minutes (actual speed/initial speed), (b) physiological index: heart rate, and (c) psychological indices: Feeling Scale: FS, Exercise Enjoyment Scale: EES, Excitement, Anxiety, RPE (Borg's scale) reported at the base line (BL), every 5 minutes (R5-R30), and 20 minutes after the end of running (A20).

RESULT and DISCUSSION

The total running distance for 30 minutes in PC (4.12±0.536km) was significantly longer than in SC (3.96±0.544km) ($t(13)=1.787$, $p<.049$). The running speed was significantly higher in the PC after 15 minutes running (R15-R25). As a result of two-way ANOVA for heart rate, a significant main effect was shown for time factor ($F(1,13)=10.306$, $p<.007$, $\eta^2=.442$). In PC heart rate was higher than in SC. But there were no differences between groups in RPE.

At 20 min after running (A20) in PC was shown to be significantly higher in enjoyment (EES) than in the SC. The anxiety in PC was significantly declined to get lower from the BL to A20 compared with the SC.

Additionally, we divided participants into the leader and the follower groups based on feedback information and examined elements of SDT. As a result of three-way ANOVA, "relatedness" in PC at post-running compared with pre-running. In other words, relatedness got significantly higher on running with partner. Especially motivation was higher in the leader group.

CONCLUSION

We found that 30-minute high-paced running with a partner lowers perceived exertion and socially enhances running performance, increasing enjoyment and reducing anxiety after running. The running influenced on the "relatedness". From the point of the relationship between leader and follower, this phenomenon particularly observed in the leader. Since it is said that experiencing positive emotion during exercise enhances intrinsic motivation (Teixeira et al., 2012), increased relatedness due to the presence of a partner is thought to be effective in facilitating exercise behavior.

RELATIONSHIP OF EMPOWERING AND DISEMPOWERING MOTIVATIONAL CLIMATES TO INDICATORS OF HONG KONG YOUTH PARTICIPANTS' SPORT CHARACTERS

SHI, Y., LEUNG, K.M., CHI, L., DUDA, J.L.

THE EDUCATION UNIVERSITY OF HONG KONG

Introduction

Coach-created motivational climates are assumed to hold significant impact on young players' sustained engagement in sport as well as their well-being and enjoyment of sport activities. It has been suggested that sport participation can promote youth participants' character development and thus contribute to their future lives in adulthood. To date, some works have been done on assessing features of the coach-created motivational climates through the theoretical lens of empowering coaching theory and in regard to indices of prosocial/character development, particularly in non-Western regions. Guided by the theoretically-integrated Empowering Coaching conceptual framework, this study aimed to assess the relationships of empowering and disempowering motivational climates to indices of youth participants' sport character, including confidence, leadership, resilience, mental toughness, and social inclusion.

Methods

651 participants were 12 to 15 years old male and female students who attended sport training offered by five partnered sport associations in Hong Kong. They responded to scales which were translated into Mandarin for Cantonese speakers from the Empowering and Disempowering Motivational Climate Questionnaire-Coach (EDMCQ-C), Self-Description Questionnaire II (SDQ II), Youth Experience Survey 2.0 (YES 2.0), and Connor-Davidson Resilience Scale (CD-RISC). Structural equation modelling (SEM) was utilized to test the hypothetical relationships among empowering, disempowering, and five aspects of sport character.

Results

The goodness of fit to the data were satisfactory ($x2/df = 2.44$, $p < .001$, RMSEA = 0.06, TLI = 0.91, and CFI = 0.92). Youth participants perceived empowering motivational climate created by coaches positively predicted their leadership, resilience, mental toughness, and social inclusion. Moreover, the empowering motivational climate has a large effect on resilience, a medium effect on leadership and mental toughness, and a small effect on social inclusion, respectively.

Discussion

This study's results support and extends the Empowering Coaching framework in regard to the prediction of youth players' indicators of character and mental strength, particularly mental toughness, resilience, and social inclusion. Based on present findings, sport coaches should be encouraged to build a more empowering climate with an emphasis on promoting greater task involvement, feelings of autonomy, and belonginess.

THE EFFECT OF EXTRINSIC MOTIVATION, ESPORT FANDOM AND IMPULSIVE BUYING BEHAVIOR OF ESPORT PERIPHERALS AMONG ESPORT FANS

WU, Y.F.
MING CHI UNIVERSITY OF TECHNOLOGY

Introduction

In recent years the popularity of esport participation has changed the way people live. With this popularity of eSport it is important to acknowledge the behaviors of eSport fans. To sustain esport fan behavior, marketing psychology is an important topic that needs to be addressed. esport fans have multiple experiences such as overlapping behavior, feelings and thoughts. To understand this phenomenon, this study will adopt social identity theory and organismic integration theory.

Methods

Purposive sampling was administered to deliver questionnaires to eSport fans that attend eSport exhibitions. The Google online questionnaire recruited 300 esport fans and after deletion of invalid data 206 were analyzed. Item analysis and convergent validity analysis was conducted using Amos. Reliability and construct validity was analyzed with SPSS 23. The purpose of this study was to investigate the relationship of extrinsic motivation, esport fandom and impulsive buying behavior of esport fans using confirmatory factor analysis (CFA) with structural equation modeling (SEM). Results

The results showed that most of the esport fans that attended the esport exhibition were males, accounting for 167 (81.1)% and females accounting for 39 (18.9)%;the age of the participants who participated in this study were between 20 to 66 years old. The results showed that identified regulation is positively relevant to esport fandom; integrated regulation is positively relevant to esport fandom; identified regulation is positively relevant to impulsive buying behavior; integrated regulation is positively relevant to impulsive buying behavior; eSport fandom is positively related to impulsive buying behavior. Discussion

The findings in this study found that organismic integration theory (OIT) and social identity theory can explain consumer regulatory styles for different forms of motivation and that greater levels of identified and integrated regulation can be affected when an individual is provided with external recognition and internal choices through contextual support. For example, if an individual identified that eSport supports their psychological needs, then they will attend more eSport events and engage in impulse buying of eSport peripherals. Therefore, these findings suggest that antecedents of eSport fandom may be affected by individuals identifying and integrating regulation reflected in their impulsive buying behavior of purchasing eSport peripheral products.

ASSESSING VARIABILITY IN HAMSTRING MUSCLE STIFFNESS AFTER ECCENTRIC EXERCISE: A SHEAR-WAVE ELASTOGRAPHY STUDY

SCHWIETE, C., BROICH, H., MESTER, J., BEHRINGER, M.
GOETHE UNIVERSITY FRANKFURT

INTRODUCTION: Shear-wave elastography is an increasingly used method to evaluate muscle stiffness after exercise-induced muscle damage [1]. Research indicates that shear-wave speed variations are not uniform across a muscle group, with notable differences between [2] and even within muscle heads [3]. This study aimed to explore the uniformity of muscle stiffness changes across and within muscle heads following maximal eccentric exercise.

METHODS: Fourteen trained male participants (26.6 ± 3.1 years, 81.8 ± 8.2 kg, 180.5 ± 7.3 cm) underwent muscle stiffness evaluation at six distinct sites within the hamstring muscle utilizing shear-wave elastography. Subjects performed 5 x 15 maximal eccentric leg curls at 210°/s on an isokinetic dynamometer and muscle stiffness was assessed before, immediately after training, and on the consecutive four days (24 h – 96 h post).

RESULTS: There was no time-by-point interaction for shear-wave elastography ($F_{25, 360} = 0.60$, $p = 0.93$). The main effects of time ($F_{4.01, 288.9} = 2.98$, $p = 0.02$) revealed a significant increase in muscle stiffness from pre (2.04 ± 0.15 m/s) to post (2.11 ± 0.14 m/s) and 24 h post (2.11 ± 0.14 m/s). A significant main effect was also observed for the specific points of measurement ($F_{5, 72} = 4.85$, $p = 0.0007$).

CONCLUSION: Maximal eccentric exercise induced an immediate and sustained increase in hamstring muscle stiffness, observable up to 24 hours post-exercise. The findings suggest spatial heterogeneity in stiffness changes across the different hamstring measurement locations, possibly due to non-uniform muscle damage [4] or fiber activation [5].

INFLUENCE OF SUBCUTANEOUS FEMORAL FAT ON THE ACCURACY OF SMO2 MEASUREMENT BY MOXY NEAR-INFRARED SPECTROSCOPY

BARAWI, S., HAPP, K.A., BEHRINGER, M.

GOETHE UNIVERSITY FRANKFURT

INTRODUCTION: The MOXY is an innovative muscle oxygen monitor that uses near-infrared spectroscopy (NIRS) to measure local oxygen saturation (SmO_2) and total haemoglobin (THb). It continuously measures muscle oxygen saturation by emitting light beams into the muscle. The reflected light is collected by two sensor in near distance [1]. Since hemoglobin and myoglobin change their absorption of infrared light due to oxygenation, NIRS measurements can be used to estimate the oxygen saturation of the muscles (SmO_2). This study investigates the effect of subcutaneous femoral fat (SFF) on the accuracy of SmO_2 measurements, addressing a significant factor that can affect NIRS readings.

METHODS: Forty participants (25.4 ± 3.5 years, 68.4 ± 13.1 kg, 173 ± 8.9 cm) had the Moxy device (Idiag AG, Switzerland) placed on the rectus femoris muscle. At 50% of the distance between the spina iliaca anterior inferior and the base oft the patella. Resting SmO2 values were recorded for 5 minutes, and the average of the last 2 minutes was analyzed. SFF thickness was measured using ultrasound (ACUSON Redwood, Siemens, USA). The linear transducer (2.9 – 9.9 MHz) head was placed vertically with as minimal pressure to prevent compression of the underlying tissue. SFF thickness was defined as the distance from the subcutaneous fat tissue-muscle interface to the subcutaneous fat tissue-skin interface. Three images were taken, and the average SFF in centimeters (cm) was used for further calculations.

RESULTS: Linear regression analysis showed a moderate positive correlation between SFF in cm and SmO2 values ($r = 0.437$, $p < .001$). SFF in cm explained approximately 19.1% of the variation in SmO2 values. The regression coefficients showed that for every cm increase in SFF, SmO2 levels decreased by -1.67 % (intercept = 91.65, $p < 0.001$; SFF = -1.67, $p = 0.005$).

CONCLUSION: These results show a clear influence of SFF on the SmO2 values, that needs to be taken into account when interpreting SmO2 values. The linear relationship shows that the data of MOXY device are impaired with increasing fat layer, reducing the validity of the information about the muscular SmO_2.Further research is needed to investigate whether the influence of subcutaneous adipose tissue can be mathematically calculated out to improve the accuracy of muscular SmO_2 measurements in people with elevated subcutaneous fat layers.

SPORTS PARTICIPATION AND PREVALENCE OF FREQUENT UPPER RESPIRATORY TRACT INFECTION

SAWADA, S., SHIMIZU, S., TSUNEDA, U., NAKAZAWA, Y., SUZUKI, K., HIRAYAMA, K., LEE, D.C.

WASEDA UNIVERSITY

INTRODUCTION: Limited data on the relationship between sports participation and health are available. In particular, few studies have investigated the relationship between contact sports such as rugby, American football, wrestling, boxing, and karate and the prevalence of frequent upper respiratory tract infection (URTI). Therefore, we conducted a cross-sectional study to investigate the relationship between contact sports and the prevalence of frequent URTI among Japanese adults.

METHODS: This study was conducted using an Internet survey between July 30, 2021 and August 3, 2021 in Japan. The study participants consisted of 2,500 adults (mean age = 26.1 years, 50% women) Participants were asked about the frequency of URTI before the COVID-19 pandemic, and were asked to select the most appropriate answer among the following options: 'a few times each year', 'about once every year', 'once every few years' and, 'rarely.' Participants were also asked if they had ever participated or are currently participating in contact sports: 'have participated in the past and currently participating [CS]'; 'have participated in the past, but not currently [Past-CS]'; and 'have never participated [Neven-CS].' We combined 'a few times each year' and 'about once each year' and defined it as frequent URTI (case) and 'once every few years' and 'rarely' as non-frequent URTI (non-case). Multivariable-adjusted odds ratios (ORs) and 95% confidence intervals (95% CIs) for the prevalence of frequent URTI were obtained using logistic regression models while adjusting for age, sex, marital status, household income, and education levels.

RESULTS: There was a total of 487 (29.3%) frequent URTI cases. Compared to the Never-CS, the ORs (95% CIs) were 1.50 (1.16 – 1.94) for Past-CS, and 2.11 (1.70 – 2.63) for CS, respectively.

CONCLUSION: This study showed a higher prevalence of frequent URTI in adults who have participated or are currently participating in contact sports. However, prospective studies are needed to find a causal relationship between contact sports participation and URTI.

WARM-UP AND INJURY PREVENTION HABITS IN AMATEUR PADEL PLAYERS

ARRIAZA, R., HERNÁNDEZ VÁZQUEZ, C., FERNÁNDEZ ROMERO, J.J.
UNIVERSITY OF A CORUÑA

INTRODUCTION: Padel is considered as the fastest-growing sport in the world. It is considered to have over 25 million players across 110 countries. Female players make up 37.5% of recreational players and 54% of padel players are 26 years old and above. It is fun, and easy to play, which makes it very attractive for people who either has never practiced sport or who quit sport long time ago and consider it as a sport without risk of injury or physical requirements. The study from Sánchez-Alcaraz (2021) showed that the total time of a match is approximately 90 minutes, while the actual playing time is slightly over 30% of the total playtime). Regarding movement analysis, the distance covered is about 2000 meters per match, although this can vary depending on the match duration and player level

There is a lack of knowledge about the injuries and injury prevention habits of amateur padel players.

METHODS: A survey was conducted with 105 amateur paddle players, who play between 1 and 3 matches of 90 minutes duration per week and compete at a low level, about their warm-up and injury prevention habits, in order to understand the reality of the sport among regular, non-professional practitioners. There were 31 male and 74 female players.

RESULTS: 46 respondents declared that they practiced also other sporting activity other than padel. Only 53 players declared that they performed some kind of warming up. The duration of the warm-up was 10 minutes or less (in one case, "one minute"), and mostly in the court, practicing different types of shots, in 32 cases; 10-15 minutes in 14 cases; and more than 15 minutes in 7 cases.

The players reported a total of 69 injuries, most of them in the lower limbs (35), and more frequently triceps surae injuries and ankle ligament sprains, followed by elbow tendinopathies (17). There were only 5 shoulder injuries (4 tendinopathies and one clavicle fracture due to a fall). There were 6 fractures (5 of them due to falls and one due to the impact of the partner's racquet in the face). In 50 cases, the injured players required more than 21 days to return to sport, and in 14 cases the injuries recurred.

CONCLUSION: Even while the frequency of the triceps surae and ankle ligament injuries is high in amateur padel tennis players, their warming-up and injury prevention habits should improve, as only 50% of the survey respondents include them into their sport protocols

EFFECT OF ACUTE INTERVENTION OF FLOSS BAND ON CHRONIC KNEE PAIN IN BOXERS

CHEN, J., WANG, Q.R., LI, Y.Z., WANG, W., WANG, D.
SHANGHAI UNIVERSITY OF SPORT

INTRODUCTION: Epidemiological data reveal that knee injuries constitutes 53% of all lower limb injuries among Chinese elite boxers, with an incidence rate of 80.9% in athletes at national level one and above. The boxing technique requires the rotation inward of knees to enhance the range of motion and power in each striking. However, this abnormal knee position leads to knee injuries and causes knee pain. Recovery from knee injuries typically spans approximately 21 days. Nonetheless, due to the systematic and protracted nature of training, athletes often struggle to get adequate rest to recover and treatment after an injury, which may ultimately result in chronic knee pain (CKP). CKP refers to knee pain that persists for more than three months. Its primary symptom is pain, which can partially impede athletes ability to compete and train normally, thus negatively influencing performance and decreasing training motivation. Floss band are a novel tool for managing injuries, functioning primarily through the application of compressive force to muscles and joints to improve function and promote recovery. Current research on floss band mainly focuses on long-term interventions. Very few studies used floss band specifically targeting at the immediate release of knee joint pain. Therefore, this study was to investigate the acute effect of floss band on boxers with CKP.

METHODS: Nine boxers (6 males: 19.3±1.6 y, 183.5±11.4 cm, 78.7±22.1 kg, trained for 3.4±1.4 y, suffering from CKP for 15.8±7.1 month; 3 females: 18.0±0.0 y, 168.8±6.8 cm, 57.2±8.7 kg, trained for 3.0±1.0 y, suffering from CKP for 9.7±5.9 month) were recruited from a provincial boxing team. After 5-minute jog and 5-minute dynamic stretching of warm-up, visual analogue scale (VAS) of knee joint pain, Lysholm knee joint function score, range of motion (ROM) of knee joint flexion, maximal isometric muscle strength of knee joint extensors and knee joint stability were measured pre- and post-intervention (a 3-minute floss band intervention with the pressure ranged 150mmHg ± 10mmHg).

RESULTS: After acute intervention of floss band, score of knee pain in boxers with CKP decreased from 4.9 (2.7, 6.0) to 2.9 (1.9, 3.5) ($Z = 2.668$, $P = 0.008$); the Lysholm knee joint function score increased from 68.2 ± 14.0 to 77.4 ± 10.2 ($t = 3.530$, $P = 0.008$); knee joint range of motion increased from 117.4 ± 7.6° to 123.7 ± 6.0°($t = 4.094$, $P = 0.003$); the maximal isometric muscle strength of knee extensors increased from 40.7 ± 12.3 kg to 50.2 ± 14.4 kg ($t = 6.070$, $P < 0.001$); and the knee joint stability increased from 15.2 (9.2, 73.0) s to 31.4 (17.5, 78.1) s ($Z = 2.310$, $P = 0.021$).

CONCLUSION: Acute intervention of floss band in boxers with CKP can significantly release the pain, reduce knee joint pain, improve Lysholm knee joint function score, increase ROM of knee joint flexion, increase maximal isometric muscle strength of knee joint extensors and enhance knee joint stability.

THE IMPACT OF ENDOMETRIOSIS ON PROPERTIES OF SKELETAL MUSCLES: A SCOPING REVIEW

HERZOG, K.M., BERNSTEIN, C., BEHRINGER, M.
GOETHE UNIVERSITY FRANKFURT

INTRODUCTION: Endometriosis is a chronic estrogen-dependent gynecological disorder characterized by the presence of endometrial tissue outside the uterus that affects approximately 10 to 15% of women of reproductive age worldwide [1]. Research suggests that the symptoms of endometriosis are due to a localized inflammatory peritoneal response triggered by ectopic implants experiencing cyclic bleeding [2,3]. Although there is evidence that physical activity can alleviate symptoms via anti-inflammatory processes, it is still unclear whether endometriosis affects the function of the skeletal muscles [4,5]. This review therefore provides a comprehensive overview of the data available to date on the influence of endometriosis on muscle contractility and muscle stiffness.

METHODS: We conducted a literature review on the influence of endometriosis on skeletal muscle characteristics. For this purpose, articles in English or German were searched in PubMed and Web of Science.The search strategy included the combination of key words 'endometriosis' and 'skeletal muscles' and 'physical activity'. The search included all topic-specific papers published during the year 1970 to 2024. Then, the findings were classified in order to summarize the evidence.

RESULTS: Using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement, 12 studies were included in this review. We grouped the studies into two major categories based on the influences of endometriosis on the skeletal muscle function that were studied: (1) endometriosis in animal studies and (2) endometriosis in human studies.

CONCLUSION: Our data indicate that endometriosis can impact muscle stiffness. Preliminary results have shown that there is an alteration in muscle stiffness due inflammatory processes. However, proposed mechanisms are often deduced from animal studies and still remain to be verified in humans with endometriosis. Although the data available to date indicate that endometriosis increases oxidative stress, consequently affects muscle elasticity and stiffness, we need high quality randomized controlled trials to confirm these results.

MEDIUM-FREQUENCY NEUROMUSCULAR ELECTRICAL STIMULATION IN CRITICALLY ILL PATIENTS PROMOTED LARGER FUNCTIONAL CAPACITY IMPROVEMENT DURING RECOVERY THAN LOW-FREQUENCY NEUROMUSCULAR ELECTRICAL STIMULATION

GUERRA-VEGA, P.1, GUZMÁN, R.2, BETANCOURT, C.2, GRAGE, M.1, VERA, C.2, ARTIGAS-ARIAS, M.3, MUÑOZ-COFÉ, R.3, VITZEL, K.F.4, MARZUCA-NASSR, G.N.3
1 CLÍNICA ALEMANA OSORNO, OSORNO, CHILE; 2 HOSPITAL BASE SAN JOSÉ OSORNO, OSORNO, CHILE; 3 UNIVERSIDAD DE LA FRONTERA, TEMUCO, CHILE; 4 MASSEY UNIVERSITY, AUCKLAND, NEW ZEALAND.

INTRODUCTION: Low-frequency neuromuscular electrical stimulation (NMES) attenuates the loss of functional capacity of Intensive Care Unit (ICU) patients. However, it has been shown that medium-frequency may be better than low-frequency NMES for the maintenance of strength, skeletal muscle mass and physical performance in healthy subjects. This study compares the effects of low- and medium-frequency NMES, along with a standard physical therapy (SPT) program, on functional capacity in critically ill patients.

METHODS: Fifty-four critically ill patients admitted into ICU and on mechanical ventilation participated in this randomized clinical trial. Participants were allocated to one of the following groups: Control Group, received a standard lower limb SPT program, 2x/day; Low-frequency NMES Group, received lower limb SPT+NMES in the quadriceps muscle at 100 Hz, 2x/day; and Medium-frequency NMES Group, received lower limb SPT+NMES in the quadriceps muscle at 100 Hz and carrier frequency of 2500 Hz, 2x/day while at ICU. Interventions were concluded when sedation cessation procedures were implemented. The functional capacity outcomes were muscle strength (MRC-SS), handgrip strength (dynamometry), thickness and quality of the quadriceps muscle (ultrasonography), functional status (FSS-ICU), degree of independence for activities of daily living (Barthel Index), functional mobility and dynamic balance (Timed Up and Go Test), and quality of life (SF-36) during hospital stay. Total days of hospitalization were also recorded.

RESULTS: Both low- and medium-frequency NMES in combination with SPT were effective strategies to improve functional capacity when compared with control group during hospital stay. Compared with low-frequency, medium-frequency NMES provided additional improvements on dynamic balance (TUG test, P<0.001), in the degree of independence to perform activities of daily living (Barthel Index, P<0.001) and quality of life (SF-36, P<0.001) prior to hospital discharge. It also promoted larger gains on functional status (FSS-ICU, P<0.05) prior to ICU discharge and in knee extension strength (MRC-SS, P<0.05) prior to intermediate care unit discharge. Finally, medium-frequency NMES induced a persistent improvement in handgrip strength earlier than low-frequency NMES (prior to intensive and intermediate care unit discharges and prior to hospital discharge) when compared with control group. Those effects could explain why the medium-frequency NMES was the only intervention to reduce total duration of hospital stay (from ICU admission to hospital discharge) in comparison to control group (P<0.05). Quadriceps muscle thickness and quality did not decrease in ICU when using either of the two NMES protocols.

CONCLUSION: Medium-frequency NMES along with a SPT program in critically ill patients showed greater benefits on functional capacity during recovery than low-frequency NMES, despite similar effects on the prevention of quadriceps muscle mass loss.

Clinical trial registration: NCT05287919.

PREDICTED RISK FACTORS FOR PATELLAR TENDINOPATHY IN ADOLESCENT BADMINTON PLAYERS USING DEEP LEARNING: A PROSPECTIVE PRELIMINARY STUDY

CHAN, Y.H., LIN, W.C.2, WU, K.P.2, LIN, C.Y.3, HUANG, T.S.1

1NATIONAL YANG MING CHIAO TUNG UNIVERSITY; 2NATIONAL YANG MING CHIAO TUNG UNIVERSITY; 3TAIPEI MUNICIPAL DATONG HIGH SCHOOL

INTRODUCTION: Badminton players frequently suffer from patellar tendinopathy (PT). Identifying the underlying risk factors of the injury is essential to mitigate the occurrence or recurrence of PT. Previous studies have not investigated the potential risk factors of PT in badminton players. Furthermore, previous prospective studies on sports injury risk factors have typically involved only a single measurement, ignoring the complex and ever-changing nature of injury risk. Regular measurements and continuous data monitoring are essential to capture changes in the data. Deep learning techniques have been used to analyze time series and process the collected data. The purpose of this prospective study was to explore the risk factors of PT by utilizing deep learning methods in adolescent badminton players. Concurrently, the deep learning analysis findings were compared with those obtained through traditional analytical methods.

METHODS: Forty-nine adolescent badminton players who exhibited no PT at the beginning of the study were recruited. The prospective study involved regular assessments twice weekly with eight measurements for four months. Measurement items included (1) training load, (2) ankle dorsiflexion range of motion (ROM), (3) thigh muscle length, (4) Y-balance test, (5) countermovement jump, and (6) agility test. The occurrence of PT within four months was evaluated. This study employed the gated recurrent unit (GRU) in deep learning to analyze time series data as a predictive model and employed SHapley Additive Explanation (SHAP) analysis to elucidate the significance of features. In traditional analysis, baseline data was utilized for logistic regression analysis, with the significance level set at 0.05.

RESULTS: Out of the 49 participants, five players experienced PT. The GRU model had an accuracy of 91.84% of prediction. The top 3 SHAP features were dominant and non-dominant ankle dorsiflexion ROM and the performance of the Y-balance test. The logistic regression analysis did not find any significant risk factors for predicting the development of PT.

CONCLUSION: This research employed deep learning methods with SHAP analysis to develop a novel predictive model. Our findings showed that essential features of developing PT were bilateral ankle dorsiflexion ROM and the performance of the Y-balance test. There were trends of decreased ankle dorsiflexion ROM and a disparity in the measurements of both legs in the Y-balance test before developing PT. The utilization of deep learning has the potential to improve the efficacy of injury prevention for PT compared to traditional analysis.

1H-NMR URINARY METABOLOMIC ANALYSIS IN RECREATIONAL ATHLETES: EFFECT OF PHYSICAL EXERCISE AND WHOLE BODY CRYOSTIMULATION.

DOUZI, W., BON, D., BIEUZEN, F., DUGUÉ, B.

UNIVERSITE DE POITIERS FACULTE DES SCIENCES DU SPORT

INTRODUCTION: Physical exercise induces various metabolic changes, influencing energy expenditure and substrate utilization. Metabolomics provides a comprehensive understanding of the metabolic adaptations occurring in response to physical exercise and recovery

METHODS: Urine metabolomics with 1H-NMR spectroscopy was used to investigate the impact of sub-maximal cycling bout (SMC) in healthy young athletes at 60 % of their peak aerobic power on urine metabolome before and after a 4-week

of high intensity interval training (HIIT) with or without the use of whole-body cryostimulation (WBC) as a recovery technique after each training session (WBC group, N=11; control group (CTL), N=12).

RESULTS: Principal component analysis (PCA) revealed a distinct separation between the urine NMR profiles of WBC and CTL groups induced by SMC. However, these changes appeared to be more pronounced in the CTL group. Targeted analyses revealed that, prior to HIIT, SMC significantly increased lactate and adenine levels in CTL group compared to WBC group. SMC resulted also in a substantial reduction in citrate and formate levels only in CTL group before HIIT. Post-HIIT, alanine level increased only in WBC group, while N-phenylacetylglutamine decreased in the WBC group compared to CTL group. However, in both groups, there was a notable increase in lactate, acetate and adenine levels accompanied by a significant decrease in formate level.

CONCLUSION: The SMC-induced changes following HIIT seem to be influenced by the repeated exposure to cryostimulation. The metabolic adaptations associated with SMC and HIIT contribute to a more comprehensive understanding of their combined effects and offer a distinctive perspective for unraveling the effects of physical activity and recovery on metabolic pathways.

DEVELOPMENT OF A VIRTUAL REALITY SYSTEM FOR EVALUATING CERVICAL SENSORIMOTOR FUNCTIONS

LIM, P.L., LAI, Y., CHENG, K., TSAI, Y.

NATIONAL CHENG KUNG UNIVERSITY

INTRODUCTION: Neck pain is increasingly prevalent due to factors such as poor posture associated with use of computers and smart phones and workplace conditions (Mahmoud et al., 2019). It affects a significant portion of the population and ranks as the second leading cause of musculoskeletal disability (Fejer et al., 2006). Sensorimotor control impairments including proprioceptive deficits, loss of eye-head coordination, poor balance and increased motion variability have been identified in patients with neck pain. In addition, visual symptoms or disturbances, such as blurred vision, words jumping on the page, or difficulty concentrating to read, often accompanied by symptoms of dizziness and unsteadiness are also often reported in patients with neck pain. Traditional clinical tests for assessing cervical sensorimotor control face challenges in setup and reliability (Kristjansson et al., 2001). Virtual Reality (VR) assessment systems offer a promising alternative, simplifying testing procedures and potentially improving reliability. However, the VR application in assessing cervical sensorimotor control is still developing. Therefore, the purpose of this study was to develop a VR system capable of assessing sensorimotor control function in the cervical spine, and investigate its test-retest reliability.

METHODS: This observational study involved 28 healthy volunteers, comprising 13 males and 15 females. All participants underwent four sensorimotor control tests including cervical range of motion, figure of eight, modified subjective visual vertical, and head tilt response using the VR system (HP Reverb G2 Omnicept, Tobii, Sweden) and self-designed virtual scenarios. All participants received the same assessment twice and test-retest reliability was evaluated using the Intraclass Correlation Coefficient (ICC).

RESULTS: The results demonstrated that all of the tests conducted with the VR system exhibited high to excellent reliability. The ICC values for cervical range of motion in directions of flexion, extension, side bending to left and right, and rotation to left and right were ranged from 0.611 to 0.870. The ICC value for the figure of eight, modified subjective visual vertical and the head tilt response tests was 0.780, 0.734, and 0.801, respectively.

CONCLUSION: This self-designed VR assessment system demonstrated high to excellent reliability in evaluating cervical sensorimotor control function. Notably, this VR system provides precise measurements, simplifies testing with its single-device capability, and enhances operational efficiency. Future applications may include clinical assessments of patients with neck pain and interactive therapeutic interventions.

THE EFFECT OF A BODYBUILDING CARBOHYDRATE-LOADING PROTOCOL ON ANTHROPOMETRY: PRELIMINARY FINDINGS FROM A RANDOMISED CROSSOVER TRIAL.

HOMER, K., JUKIC, I., CROSS, M., HELMS E.

AUCKLAND UNIVERSITY OF TECHNOLOGY

INTRODUCTION: To acutely enhance appearance and thus performance, bodybuilders implement carbohydrate (CHO) loading protocols in the week before the competition (known as peak week [PW]) to increase muscle size through the supercompensation of muscle glycogen. While the use of such strategy is seemingly prevalent, experimental designs in the context of bodybuilders are lacking, whereby the only existing trial is limited. Thus, the aim of this study was to assess the effect of an ecologically valid bodybuilding CHO-loading protocol on anthropometric measures.

METHODS: Four dieting, resistance-trained males who met the inclusion criteria of ∑8 skinfolds (SF) ≤48mm (range: 34.5-45mm) participated in this randomised crossover design. This criterion was used to replicate the very low body fat levels of male bodybuilders during PW. Participants were also dieting for ≥8 weeks to represent the physiological conditions of bodybuilders during competition preparation. Each experimental period, separated by a 9-day wash-out, consisted of

data collection on days 1, 4, and 5 which correspond to baseline, post-depletion, and post-loading phases of the protocol, respectively. During depletion, participants followed a standardised training regime and diet (2.2-2.6g/kg protein, 1-2g/kg CHO, 0.5g/kg fat relative to body mass (BM)) representative of the practices of bodybuilders during PW. This diet was maintained on day 4 with the addition of placebo (PLA) or CHO shakes which contained 9g/kg CHO for the post-loading data collection on day 5. Outcomes comprised of BM, SF, and ∑5 ultrasound muscle thickness (MT) which were obtained at each data collection in the morning at the same time (±1hr) after an overnight fast. Descriptive data at the group level from each day was used to assess changes.

RESULTS: From baseline, BM (CHO: 76 to 75.5kg; PLA: 75.4 to 75.1kg), SF (CHO: 38.9 to 37.6cm; PLA: 38.8 to 38.8mm), and MT (CHO: 23.9 to 23.7mm; PLA: 24.3 to 24.1mm) mostly decreased following depletion in both conditions. After loading, all outcomes increased in the CHO condition (BM: 76.1kg, SF: 38mm, MT: 24.4cm) but not in PLA (BM: 74.7kg, SF: 38.6mm MT: 24.1cm) from post-depletion. However, these changes were not as pronounced in comparison to the baseline in both conditions.

CONCLUSION: The implementation of a bodybuilding CHO-loading protocol may not meaningfully change BM, SF, and MT following the ingestion of 10-11g/kg of CHO in a day. While small group level changes seemingly favour CHO-loading, it is difficult to interpret these differences as large enough to exceed potential measurement error and daily biological fluctuations, and thus may not represent a meaningful change. Based on the preliminary findings, it can be interpreted that it may not be worthwhile for competitors to implement such a drastic protocol. However, outcomes such as change in visual appearance need to be quantified to fully elucidate the effects of the protocol on bodybuilding performance.

EFFECT OF TIME RESTRICTED EATING (16/8) AND AEROBIC EXERCISE ON FAT MASS AND WAIST CIRCUMFERENCE IN FEMALES WITH OBESITY: A PILOT RANDOMIZED CONTROLLED TRIAL

DAI, Z., WAN, K., ZHANG, S., WONG, S.H.

THE CHINESE UNIVERSITY OF HONG KONG

INTRODUCTION: This pilot randomized controlled trial aimed to investigate the effects of time-restricted eating (TRE), aerobic exercise, and their combination on fat mass and waist circumference in females with obesity. Additionally, the study aimed to determine whether the combination of TRE and aerobic exercise produces superior changes in body composition compared to each intervention alone.

METHODS: A total of 48 female participants with obesity were randomly assigned to one of four intervention groups: (1) TRE group (≤8-hour daily eating window, with ad libitum energy intake), (2) aerobic exercise group (three moderate-intensity exercise sessions per week), (3) combination group (TRE plus aerobic exercise), or (4) control group. The interventions were conducted over a 12-week period in free-living settings. Fat mass and waist circumference were measured at baseline and after the intervention.

RESULTS: Of the 48 participants who underwent randomization, 47 completed the 12-week intervention. After the intervention, fat mass and waist circumference decreased in the aerobic exercise, TRE, and combination groups, but there were no significant differences between the groups. However, participants in the combination group showed a statistically significant reduction in fat mass from 25.07 ± 2.31 kg to 23.33 ± 2.31 kg compared to the control group (p=0.047). In terms of waist circumference, both the aerobic exercise group (-6.02 cm; 95% CI -0.01 to -12.03) and the combination group (-6.50 cm; 95% CI -0.64 to -12.40) showed significant decreases compared to the control group (p=0.049 and p=0.021, respectively).

CONCLUSION: This pilot randomized controlled trial suggests that both TRE and aerobic exercise interventions are effective in reducing fat mass and waist circumference in females with obesity. Moreover, the combination of TRE and aerobic exercise appears to have an additive effect on fat loss. Further research with larger sample sizes and longer intervention durations is warranted to confirm these findings and explore the impact on fat mass and waist circumference.

EFFECTS OF TIME-RESTRICTED EATING COMBINED WITH ENDURANCE OR RESISTANCE TRAINING ON BODY COMPOSITION IN MALES

CORREIA, J.M., PEZARAT-CORREIA, P., MINDERICO, C., MENDONÇA, G.

POLITÉCNICO DO PORTO

INTRODUCTION: Improving body composition by increasing muscle mass and decreasing fat mass is a common approach for eliciting positive health outcomes and augmenting athletic performance. Many people aiming at modifying body composition combine dietary strategies with regular exercise. We sought to explore the effects of four weeks of time-restricted eating (TRE) vs. regular diet, combined with endurance or resistance training, on body composition of trained young males.

METHODS: The order of dieting was randomized and counterbalanced, and participants served as their own controls. As in one previous study, a two-week washout period (no specific diet or exercise) separated both conditions. The experimental design consisted of two dietary interventions: (1) four weeks of TRE, in which 100% of energy intake was restricted to a time window of 8-h each day, and (2) four weeks of regular diet (non-TRE), in which 100% of energy intake were freely distributed throughout the 24-h day. Height and body mass were used to calculate body mass index (BMI). Each participant was scanned with dual-energy X-ray absorptiometry at baseline and post-intervention. The participants followed structured training routines during each dietary intervention, with a frequency of 3 times/wk (endurance group: 10 km of continuous heavy-outdoor running + 1 severe running bout of 1000 m; resistance group: 4 sets of maximum repetitions at

85% one-repetition maximum - five multi-joint dynamic full body exercise routine). One-way repeated measures ANOVA was used to determine baseline differences between conditions on body composition variables. ANCOVAs were computed for the change in each variable over time, using baseline measures as covariates.

RESULTS: There were no significant differences between groups or conditions at baseline. The results from ANCOVA indicate that, in both groups, TRE elicited a greater magnitude of decrease in BMI than the non-TRE condition (F=4.2, p=0.048; ES=0.128). Moreover, we found a significant group main effect on fat-free mass (FFM) (p=0.024) indicating that, regardless of diet, the resistance training group exhibited greater magnitude of change in FFM at post-intervention time point. No other variable (i.e. fat-free mass, absolute or relative fat mass) was affected by either intervention over time.

CONCLUSION: In conclusion, four weeks of TRE can be used with endurance running or resistance training to elicit BMI reductions in trained young males. However, when compared to that seen with a regular diet, TRE does not offer any additional benefit for potentiating meaningful changes in body composition during the course of 4 weeks of endurance or resistance training.

EFFECTS OF INTERMITTENT FASTING AND EXERCISE WINDOW ON WEIGHT LOSS AMONG OBESE WOMEN

HANIM HAMZAH, S., MD AKIR, S., SELVANAYAGAM, V.S., JAAFAR, Z., MUSTAFA, N.

UNIVERSITI MALAYA

INTRODUCTION: Intermittent Fasting (IF) is reported to produce significant weight loss for long-term intervention and promotes adherence. In addition, its combination with the right exercise plan may produce a greater impact on weight loss. Therefore, it is important to identify the suitable exercise window to address the desired outcome when designing IF and exercise intervention program for weight loss. The aim of this study was to examine the effect of exercise during fasting and eating state among obese and sedentary women performing IF on body weight status.

METHODS: Thirty-four women aged between 30-55 years old with BMI ≥25 were recruited in this 6-week weight loss intervention program. In this randomised control trial design, the participants performed the modified alternate day fasting (MADF) and exercise (functional training). They were divided into exercise during MADF fast-state (FastE, n=17) and exercise during MADF eating-state (EatE, n=17) groups. The exercise were designed in a form of circuit training of 7-8 different stations or movements during the intervention. Body weight, body mass index (BMI), fat mass (FM) and fat free mass (FFM) were measured at pre- and post-intervention. A statistical level of $p < 0.05$ was accepted. All data are expressed as mean ± SD.

RESULTS: Seventeen participants (FastE, n=8, age 41.9±6.0 yrs, BMI 31.3±5.6,) and (EatE, n=9, age 41.3±6.5 yrs, BMI 29.5±2.5) completed the intervention. The results of this study showed that body weight was significantly reduced by 1.89 ± 2.26 kg in the FastE group and by 1.21±0.96 in the EatE group after 6-week intervention. We found that BMI, FM and FFM were significantly reduced in the EatE group but not significant in the FastE group. However, the reduction of BMI and FM were higher in FastE (by 0.75 ± 0.94 and by 1.00 ± 1.79 kg, respectively) compared to EatE (by 0.40 ± 0.38 and by 0.71 ± 0.84 kg, respectively). However, greater FFM reduction in FastE (by 0.79 ± 1.64 kg) compared to EatE (by 0.50 ± 0.44 kg).

CONCLUSION: The exercise during IF (fast-state) intervention program produced a comparable improvement in body weight, BMI and FM to exercise during IF (eating-state). However, this conclusion cannot be established based on the small number of participants who completed the intervention due to the high rate of dropout. Improving the adherence of this IF and exercise intervention program may provide more pronounced results.

COMPARING ACCEPTANCE AND WEIGHT CHANGES OF PROVIDED INTERMITTENT FASTING, OMNIVOROUS OR VEGAN DIETS: A SECONDARY OUTCOMES ANALYSIS.

KEENAN, S., AL-REFAI, W., COOKE, M., CAMERA, D.

SWINBURNE UNIVERSITY

INTRODUCTION: Control of dietary variables, in particular intake of dietary energy (and subsequently energy balance) and protein, is important when undertaking human nutrition research studies. To adequately control energy balance and reach a certain level of protein intake, food and beverages are sometimes provided to participants, and in order to maintain high rates of adherence, these diets need to be effective, palatable and acceptable. This research reports on secondary diet acceptability and weight outcomes following short-term (i.e., 2-week) intermittent fasting, vegan, and omnivorous diets in recreationally active males.

METHODS: Participants were randomly allocated to one of three dietary groups: Intermittent Fasting (IF, n=6, 26.7±2.1yrs, BMI 26.0±1.2), Omnivorous (Omni, n=7, 25.9±1.5yrs, BMI 24.6±1.4), and Vegan (n=9, 25.3±2.2yrs, BMI 25.8±1.3). Each group underwent a 2-week dietary intervention, where all meals and snacks were provided on a 3-day rotating menu, with changes made only to breakfast, lunch, and dinner (snacks provided were consistent). Food provision included frozen main meals, pre-packaged snacks, and protein supplements. The IF group consumed ~30% of their energy requirements via protein supplements on two, non-consecutive days per week, while the other 2 groups (euenergetic) consumed 100% of their estimated requirements daily. All 3 groups consumed an average of 1.6 grams of protein per kilogram of bodyweight per day. Weight was recorded daily, and diet acceptability was determined at the end of the study utilising the Food Acceptability Questionnaire, which consists of 7 questions utilising 7-point Likert scales.

RESULTS: The IF group exhibited a significant weight loss of -1.8kg ± 0.5kg post-intervention, while the other groups did not show significant changes in weight (Omni = -0.6 ± 0.7kg, Vegan = 0.0 ± 0.5 kg), indicating a negative energy balance in the IF group, and neutral energy balance in the remaining two groups. There were no statistically significant differences in

ratings of acceptability of the diets, although those in the IF group rated the diet as requiring less effort to maintain (median [range] = 6 [4-7] vs Omni = 3 [3-7] and Vegan = 4.5 [1-6]).

CONCLUSION: Dietary acceptability was equal across all diets over a short-term intervention, with the addition of 2 fasting days per week having no significant impact on these outcomes. Furthermore, changes in weight indicated that the intended energy balance was achieved over this 2-week period. These results indicate that controlling energy and protein intake via provided food is equally acceptable to participants across the three diets studied when pre-packaged food was provided, and effective for controlling participant weight over a short-term intervention.

ASSOCIATIONS AMONG ENERGY AVAILABILITY AND SLEEP QUALITY IN ELITE SWIMMERS

DE SOUZA, M.J., LUNDSTROM, E., WILLIAMS, N.
PENN STATE UNIVERSITY

INTRODUCTION: There is a high prevalence of poor sleep quantity and quality in athletes, and similarly, there is often a high prevalence of low energy availability (EA) in endurance athletes. Poor sleep quality during high training loads has been identified as an early sign of overreaching, which may result in improper recovery and limit training adaptations. Similarly, adequate energy availability (EA) is necessary to sustain physiological function and prevent training maladaptation in athletes. Previous data support worsened sleep quality during periods of heavy training in swimmers and low EA has been demonstrated in athletes during periods of heavy training. Endurance athletes during heavy training may experience both poor sleep quality and low EA, which may affect a range of training metrics. As well, emerging evidence supports a role of EA in sleep quantity, however, it is still unclear how EA affects sleep quality among athletes. Therefore, our objective was to determine the interrelationships between EA and sleep quality, where we assessed EA via 3-day diet log and daily exercise energy expenditure, and matched data collection for sleep quality (sleep duration (hrs), sleep debt (hrs), and hours and % of: slow wave sleep (SWShrs and SWS%), rapid-eye movement (REMhrs and REM%)), via a wearable device.

METHODS: In 26 elite male (n=10) and female (n=16) collegiate swimmers, data were collected over 2-weeks of heavy training. Frequency analysis was used to determine the number of athletes meeting or exceeding current athlete sleep duration recommendations. Pearson correlations were utilized to determine relationships between variables unless sex effects existed in which case linear regression analyses were utilized to control for sex-differences.

RESULTS: In all swimmers, 42% (11/26) had a sleep duration ≥ 7hrs. 38% (6/16) female swimmers and 50% (5/10) male swimmers achieved a sleep duration ≥ 7hrs. There was a trend toward a correlation between EA and sleep duration in all swimmers (R=0.33; P=0.06). EA positively correlated with REMhrs (R=0.64; p=0.001). EA was not related to sleep debt. Regression analyses revealed that when controlling for sex, EA was a predictor of SWShrs (R2 = 0.448; F=9.35, p<0.001). Controlling for sleep duration, EA was a significant predictor of REMhrs (R2 = 0.425; F=8.509, p<0.002). Similarly, when controlling for sleep duration, EA was a significant predictor of sleep debt (R2 = 0.261; F=4.055, p<0.031).

CONCLUSION: Significant relationships were found between EA and sleep quality in all swimmers, where elite swimmers with lower EA exhibited worse sleep quality. To avoid negative consequences of poor sleep quality and low EA, athletes should consume adequate calories to support energy needs and optimize sleep quality. Future research should explore underlying mechanisms and whether low EA causally impacts sleep quality.

THE INTERPLAY BETWEEN RESISTANCE EXERCISE AND TIME-RESTRICTED EATING: STRONGER TOGETHER THAN ALONE?

STIRCU, V., SAMPIERI, A., PAOLI, A., MORO, T.
UNIVERSITÀ DEGLI STUDI DI PADOVA

INTRODUCTION: The 16/8 method of intermittent fasting (IF), also known as time-restricted eating (TRE), is often associated with positive health effects. However, the role and interplay of TRE and exercise remain unclear. Building on the results of a study that investigated the effects of the TRE protocol in association with resistance training (RT), this study aims to explore the differences between combining training and TRE versus diet alone.

METHODS: We selected 40 subjects and divided them into a total of four groups of 10 people each. Twenty subjects (age 29.1±4.1; weight 83.5±5.9 kg) were part of a previous study by Moro et al. (2016), who had undergone resistance training. These were further divided into two groups: one followed a time-restricted eating (TRE) regimen (n=10), and the other followed a standard diet (SD; n=10). We compared these twenty trained subjects against 20 other subjects (age 42.05±13.6; weight 73.11±14.8 kg) who did not engage in physical exercise. This new group was also divided into two: one followed time-restricted eating (TRF; n=10) and the other a standard diet (SD; n=10). The TRE groups fasted for 16 hours and consumed three meals over an 8-hour period at 1 p.m., 4 p.m., and 8 p.m., while the SD groups ate at 8 a.m., 1 p.m., and 8 p.m. Subjects were tested before and after 8 weeks of their assigned intervention. We measured body composition (fat mass, fat-free mass) using dual-energy X-ray absorptiometry and conducted blood analysis for total and free testosterone, insulin-like growth factor 1, blood glucose, insulin, leptin, triiodothyronine, thyroid-stimulating hormone, interleukin-6, interleukin-1β, tumor necrosis factor α, total cholesterol, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, and triglycerides.

RESULTS: After 8 weeks, a significant effect of intermittent fasting on weight was observed, with TRE pre compared to TRE post showing a significant difference (p=0.002). A 2-way ANOVA (Time * Diet interaction) revealed a decrease in fat mass (p< .001), %FAT (p< .001), and BMI (p=0.003) in TRE pre compared to TRE post, while fat-free mass was maintained in all groups. Testosterone and insulin-like growth factor 1 levels decreased, considering the interaction of time * diet (p=0.075;

p=0.033), and glucose levels also decreased in the group combining exercise and TRE compared to their levels post-exercise and TRE (p=0.010).

CONCLUSION: These preliminary data suggest that physical exercise, particularly resistance training in relation to TRE, appears to improve glucose levels in subjects. Furthermore, intermittent fasting is confirmed as an interesting strategy for weight loss and muscle mass maintenance.

THE EFFECT OF ACUTE MODERATE-INTENSITY CONTINUOUS RUNNING ON OXYNTOMODULIN CONCENTRATIONS IN HEALTHY MEN AND WOMEN.

JIN, Z., LI, J., THACKRAY, A., KING, J., STENSEL, D.
LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Oxyntomodulin (OXM) is an appetite-related gut hormone, implicated in weight management through its roles in reducing energy intake, and increasing energy expenditure. This study examined 1) the effect of acute moderate-intensity continuous running on oxyntomodulin concentrations; and 2) whether exercise-induced oxyntomodulin fluctuations are correlated with subsequent energy intake.

METHODS: 20 healthy-weight individuals (10 men, 10 women; age: 25 ± 4 years; BMI: 22 ± 2 kg·m-2 (mean ± SD)) completed two, 3.5-hour trials, exercise (EX) and control (CON), in a randomised order. Participants were required to fast overnight and engaged in a 60-minute treadmill run at 70% of their peak oxygen uptake (EX) or rested (CON) for the first hour of each trial. Participants then remained in the lab for an additional 2.5 hours and were served an ad libitum pasta meal one-hour after completion of exercise/rest i.e., at 2 hours. Blood samples were collected to measure oxyntomodulin concentrations at baseline (t = 0 minute), immediately after-exercise/rest (t = 60 minutes), and every 30 minutes thereafter up to 210 minutes (3.5 hours).

RESULTS: Linear mixed model analysis indicated no significant main effect of exercise on OXM concentrations ($p = 0.227$). However, a significant trial by time interaction was noted ($p = 0.041$). At t = 60 minutes, control was associated with a decrease in OXM concentrations relative to baseline, while the exercise trial exhibited an increasing trend. No significant differences were observed in time-averaged total area under the curve (tAUC) or incremental area under the curve (iAUC) for OXM between the exercise and control trials. Absolute energy intake (EI) remained unaffected by exercise. However, exercise led to a significant reduction in relative EI ($p < 0.001$) when considering the energy expended during exercise. No significant correlations were identified between OXM tAUC or iAUC and absolute EI.

CONCLUSION: Acute moderate-intensity exercise transiently modulates OXM concentrations. However, these exercise-induced alterations in OXM do not last and do not translate into changes in subsequent energy intake, at least in the short term.

EFFECTS OF REPEATED SPRINT CYCLING DURING THE LUTEAL PHASE ON FOOD REWARD IN FEMALE ATHLETES

KAMEMOTO, K., MIYAGUCHI, A., WANIFUCHI, M., HIRAMATSU, J., HAYASHI, N., SAKAMAKI-SUNAGA, M.
NIPPON SPORT SCIENCE UNIVERSITY

INTRODUCTION: Increased appetite before menstruation is a symptom of premenstrual syndrome, and is observed in many female athletes (Kamemoto K et al., 2021). While appetite can be divided into homeostatic and non-homeostatic system, premenstrual increase in appetite also includes changes in the reward system of appetite control, which is classified as non-homeostatic appetite (Strahler J et al., 2020). Although a recent study revealed acute exercise altered food reward in healthy males (Thackray AE et al., 2023), no study has investigated the influence of acute exercise on food reward in females. This study examined the effects of acute high-intensity exercise on the food reward system during the luteal phase (the premenstrual phase) in female athletes.

METHODS: Four female athletes (age: 21.8 ± 1.0 years; VO2 peak: 39.6 ± 9.7 mL/kg/min) with normal menstrual cycles, completed a resting trial (RE) and exercise trial (EX) in the luteal phase. In the exercise trial, after consuming a standard breakfast (29.3 kj/kg body weight) and seated rest for 45 min, participants performed repeated sprint cycling (consisting of two sets of 8 × 6-second maximal pedalling with a 30-second recovery period). Blood samples, subjective appetite and food reward data were obtained and assessed before exercise (PRE) and immediately post-exercise (POST). Food reward and subjective appetite were assessed by the Leeds Food Preference Questionnaire in Japanese (LFPQ-J) and a visual analogue scale (VAS), respectively. The LFPQ-J is a computer-based task that directly measures explicit liking and wanting, and indirectly measures implicit wanting using images of 16 foods familiar to the Japanese, including high-fat savoury, low-fat savoury, high-fat sweet and low-fat sweet foods (Hiratsu A et al., 2022). The luteal phase was confirmed by serum progesterone and estradiol concentrations. All participants were asked to record their food intake for the trial day. Statistical significance was set at $P < 0.05$. Effect sizes (ES) (Cohen's d) were calculated to indicate the magnitude of the differences between trials.

RESULTS: Overall, subjective appetite scores were higher in EX than RE ($P < 0.05$, ES = 0.58), indicating that participants were hungrier in RE than EX. The results of LFPQ-J showed that relative preference for high-fat foods was higher in RE than EX in POST ($P < 0.05$, ES = 0.52), but with no significant differences between the trials in PRE ($P = 0.23$, ES = 0.13). There was a main effect of trial on taste appeal bias, with EX having higher values than RE ($P < 0.01$, ES = 0.34). It means that participants were more likely to prefer sweet foods during exercise trials. Energy, protein, and fat intake after the trial were significantly higher in RE than EX (all for $P < 0.01$).

CONCLUSION: Repeated sprint exercise by female athletes during the luteal phase decreases appetite, particularly the preference for high-fat foods.

A SURVEY OF PREVALENCE, KNOWLEDGE, AND PRACTICES TOWARD IRON-DEFICIENCY AND IRON-DEFICIENCY ANEMIA AMONG AMATEUR FEMALE LONG-DISTANCE RUNNERS IN POLAND

GREN, A., KASZUBA, M.1, PIATKOWSKA, E.2, SADOWSKA-KREPA, E.1, FILIP-STACHNIK, A.1
1THE JERZY KUKUCZKA ACADEMY OF PHYSICAL EDUCATION IN KATOWICE; 2UNIVERSITY OF AGRICULTURE IN KRAKOW

INTRODUCTION: In recent years, long-distance running has become a popular sport, while iron deficiency (ID) and iron deficiency anemia (IDA) are common in long-distance runners. Although there has been a recent and rapid growth in understanding of the negative impact of ID and IDA on the health and physical performance of female runners, there is a lack of data about athletess knowledge in this field. This study aimed to evaluate the prevalence, knowledge of long-distance runners about ID and IDA and their causes, prevention, and treatment.

METHODS: A sample of 167 Polish amateur female long-distance runners completed a survey focused on dietary habits, knowledge of ID and IDA, prevention, and treatment practices.

RESULTS: The occurrence of ID and IDA was reported by 60% and 38% of women, respectively. 19% of the subjects followed a vegetarian or vegan diet, and 52% of them reported ID or IDA. Women who reported IDA believed that iron was important in their diet in comparison to those without IDA ($p < 0.02$). There was a statistically significant correlation between lack of knowledge of the iron role ($p < 0.009$), iron sources ($p < 0.001$), iron absorption ($p < 0.001$), vegan or vegetarian diet ($p < 0.009$), weight loss practices ($p < 0.016$), and the occurrence of ID or IDA. 74% of the women did not know the difference between heme and non-heme iron, which influenced the wrong identification of their sources ($p < 0.005$). Only 37% of women who reported IDA correctly indicated the difference between heme and non-heme iron ($p < 0.048$).

CONCLUSION: IDA and ID are important health issues among amateur female long-distance runners. Insufficient knowledge and nutrition practice among them may lead to ID or IDA, especially in vegans and vegetarians. Women who have experienced IDA present greater awareness of iron in their diet. These results highlight the need for education to ensure proper prevention practices and minimize the risk of ID and IDA among amateur female long-distance runners.

THE EFFECTS OF 8 WEEKS POST EXERCISE HOT WATER IMMERSION ON CARDIORESPIRATORY FITNESS, VASCULAR HEALTH AND CARDIOMETABOLIC HEALTH IN PHYSICALLY INACTIVE MIDDLE-AGED ADULTS

STEWARD, C., HILL, M., MENZIES, C., RUSSELL, S., PUGH, C., THAKE, D., CULLEN, T.
COVENTRY UNIVERSITY

INTRODUCTION: Heat therapy can replicate some of the long-term adaptations of exercise training which underpin improvements in cardiovascular health [1]. It is estimated that 25% of adults do not meet the minimum recommended physical activity guidelines [2]. However, many take part in irregular, less intense and infrequent bouts of physical activity within their weekly routines. The use of hot water immersion after exercise has the potential to augment the cardiovascular health benefits from smaller amounts of exercise. Therefore, this study investigated whether post exercise hot water immersion (EX+HWI) can improve cardiovascular health by a greater extent than post exercise thermoneutral water immersion (EX+TNWI).

METHODS: After ethical approval, twenty-four physically inactive middle-aged adults (14 females and 10 males; age: 58 ± 5 years; weight: 78 ± 12 kg; height: 1.67 ± 0.08 m; VO2 peak: 18 ± 3 ml/kg/min-1) were randomised to either 8-weeks of EX+HWI (n=12) or EX+TNWI (n=12). Volunteers visited the laboratory 2-4 times per week to take part in exercise plus immersion sessions (total 24 sessions). The exercise component was for a duration of 30 minutes and consisted of 10 minutes cycling, rowing and brisk walking at 65%-75% of heart rate maximum. Water immersion was for 30 minutes at a temperature of either 40 °C or 34 °C. A range of cardiovascular health parameters were measured pre, midway and post intervention, including cardiorespiratory fitness, blood pressure, brachial artery endothelial function, carotid to femoral arterial stiffness and serum cardiometabolic/inflammatory biomarkers.

RESULTS: A time × condition interaction was detected for mean arterial pressure (P=0.039) and diastolic blood pressure (P=0.044). EX+HWI resulted in a greater reduction in mean arterial pressure and diastolic blood pressure at midway (MAP: P<0.001, mean difference= 5 mmHg and DBP: P=0.001, mean difference=5 mmHg) and post (MAP: P=0.011, mean difference= 4 mmHg and DBP: P=0.007, mean difference=4 mmHg) intervention in comparison to EX+TNWI. Furthermore, a main effect of condition was apparent for systolic blood pressure (P=0.003, mean difference=4 mmHg) and central arterial stiffness (P=0.048, mean difference=2.08 m/s). There were no differences between conditions for cardiorespiratory fitness, brachial artery endothelial function and serum cardiometabolic/inflammatory biomarkers (P>0.05).

CONCLUSION: Eight weeks of post exercise hot water immersion improved vascular health through reducing blood pressure and central artery stiffness to a greater extent than exercise followed by thermoneutral water immersion in physically inactive middle-aged adults.

THE EFFECTS OF SIMULTANEOUS ISOMETRIC AND ECCENTRIC EXERCISE ON CARDIOVASCULAR FUNCTION IN YOUNG NORMOTENSIVE INDIVIDUALS.

BAROSS, T., BAXTER, B., WRIGHT, B., LANGDON, D., KAY, A.
UNIVERSITY OF NORTHAMPTON

INTRODUCTION: The World Health Organisation has reported hypertension, a major risk factor for stroke, coronary heart disease and cardiovascular-related mortality to be near epidemic levels globally with over 30% of the world's population affected. Individually, isometric resistance training (IRT) has been established as one of the most efficacious nonpharmacological interventions for the prevention and treatment of hypertension, whilst eccentric exercise has also demonstrated improved cardiometabolic health in older populations (1). Simultaneous training (aerobic and isometric) produces larger reductions in resting blood pressure (BP) compared to single exercise protocols (2), however the effects of simultaneous isometric and eccentric training on cardiovascular parameters remain unknown. Therefore, the purpose of this study was to determine the effects of a 6-week simultaneous IRT and eccentric or concentric exercise intervention on resting cardiovascular parameters in young normotensives.

METHODS: Fifty-four normotensive individuals (33 men, age = 21 ± 1 yr; 21 women, age = 20 ± 1 yr) were randomly assigned to four groups: simultaneous isometric exercise and stair descent (ISO-ECC, n = 14), simultaneous isometric exercise and stair ascent (ISO-CON, n = 13), isometric handgrip exercise (ISO, n = 13), or a passive control (CTRL, n = 14). Resting BP and haemodynamics (cardiac output, stroke volume, systemic vascular resistance) were measured prior to and after an incremental 6-week (3 day/week) training period. Initially participants completed 9 reps (1 repetition = 108 steps) of either stair ascending or descending in each session with the number of reps increasing by three each week. Sessional rate of perceived exertion was measured following each training session.

RESULTS: The two-way ANOVA revealed a significant interaction effect ($F_{3,48} = 3.198$, $P = 0.032$, $\eta_p^2 = 0.167$) for resting systolic BP (SBP), with significant ($P < 0.05$) reductions in all training groups (ISO, 8 ± 9 mmHg; ISO-ECC, 8 ± 5 mmHg; ISO-CON, 6 ± 4 mmHg). SBP was significantly lower post-training in ISO compared to CTRL (10 ± 16 mmHg). No significant changes were revealed for all other measures ($P > 0.05$).

CONCLUSION: All three training modalities were identified as efficacious therapeutic exercise interventions to lower SBP, however the magnitude of the change in SBP was greater in both the ISO and ISO-ECC groups, which were also perceived to be less demanding than the ISO-CON exercise. Although these results support the limited published data highlighting the hypotensive effects of eccentric exercise, as there was no difference in the reported decreases in SBP between the ISO and ISO-ECC groups, it may be more appropriate and time efficient to use the established isometric intervention if BP reduction is the main goal of the therapeutic exercise intervention.

DESPITE IMPAIRED MICROVASCULAR FUNCTION IN MALES OF BLACK-AFRICAN DESCENT, ACUTE HOT WATER IMMERSION ELICITS SIMILAR BLOOD PRESSURE AND MICROVASCULAR RESPONSES AS IN SOUTH-ASIANS AND WHITE-EUROPEANS

BELLINI, D., LLOYD, A., HAVENITH, G., LEICHT, C.A., BAILEY, S.J., ROBERTSON, A., MALEY, M.
LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Impaired microvascular function in individuals of Black-African (BA) and South-Asian (SA) descent compared to White-Europeans (WE) suggests greater endothelial dysfunction, contributing to an increased risk of cardiovascular disease (CVD). The associated reduction in CVD risk from chronic passive heating (e.g., hot baths or sauna bathing) has been suggested to be underpinned by the repeated strain from acute exposures. Therefore, we investigated the effect of acute hot water immersion (HWI) on blood pressure and microvascular responses compared to a thermoneutral control (CON) between BA, SA, and WE individuals.

METHODS: Thirty-one recreationally active males (10 BA, 11 SA, 10 WE) completed a submaximal cycling test to determine VO2peak. Thereafter, two experimental visits of HWI (39.0°C) or CON (36.0°C) were completed, involving 30-minutes of shoulder-height, then 30-minutes of waist-height immersion. Venous blood samples were collected immediately pre- and post-immersion, and blood pressure was assessed throughout immersion. Following an additional 60-minutes of seated thermoneutral rest, forearm and toe cutaneous vascular conductance (CVC) responses to occlusion (OC) and local heating (LH) were investigated.

RESULTS: After both immersion protocols, baseline CVC was similar between racial groups. During OC, peak forearm CVC was lower in BA (0.51 ± 0.21 flux/mmHg) than SA (0.87 ± 0.21 flux/mmHg) and WE (0.85 ± 0.21 flux/mmHg; $p < 0.001$). Peak toe CVC was also lower in BA (2.46 ± 0.74 flux/mmHg) than SA (3.32 ± 0.74 flux/mmHg) and WE (3.80 ± 0.74 flux/mmHg; $p < 0.013$), in addition to a reduced area under the curve (BA: 8983 ± 4835, SA: 14087 ± 4836, WE: 18005 ± 4836 flux/s; $p < 0.023$). Furthermore, toe CVC responses to 42°C LH were attenuated in BA (1.08 ± 0.82 flux/mmHg) compared to SA (2.00 ± 0.82 flux/mmHg) and WE (2.13 ± 0.78 flux/mmHg; $p < 0.033$), as well as to 44°C LH (BA: 1.26 ± 0.78, SA: 2.29 ± 0.78, WE: 2.13 ± 0.78 flux/mmHg; $p < 0.020$). During immersion, HWI reduced both systolic (-7 ± 7 mmHg; $p < 0.019$) and diastolic (-16 ± 5 mmHg; $p < 0.001$) blood pressure compared to CON, with no differences observed between racial groups. HWI increased toe CVC during 44°C LH (2.07 ± 1.07 flux/mmHg) compared to CON (1.72 ± 0.7 flux/mmHg; $p = 0.039$), despite no change in plasma [nitrite] or differences between racial groups ($p > 0.05$).

CONCLUSION: Between racial groups, microvascular reactivity to OC and LH were lower in BA than SA and WE individuals. Despite this racial difference in microvascular function, the beneficial effects of HWI on blood pressure and CVC were similar between individuals of BA, SA, and WE descent.

EFFECTS OF ACUTE AEROBIC EXERCISE FOR UPPER OR LOWER LIMBS ON SEGMENTAL ARTERIAL STIFFNESS

NISHIWAKI, M., KUME, D., KIKUCHI, K.
OSAKA INSTITUTE OF TECHNOLOGY

INTRODUCTION: Many previous studies have demonstrated that acute or regular exercises reduce Pulse Wave Velocity (PWV) as an index of arterial stiffness. The increased arterial stiffness is an independent risk factor for future cardiovascular diseases or mortalities, so preventing arterial stiffness by exercise is of paramount importance, regardless of age. In recent, one-legged physical exercise (aerobic, resistance, and stretching) has been shown to acutely reduce arterial stiffness in the exercised limb, but not in the none-exercised limb. These findings thus raise the possibility that arterial stiffness responses and adaptations to exercise are mainly involved in physical exercise-induced local factors as exercise stimuli. However, the influences of acute exercise types on segmental arterial stiffness are now well unknown. Therefore, this study aimed to examine the effects of acute aerobic exercise for upper or lower limbs on segmental arterial stiffness.

METHODS: Twelve young adults (22 ± 1 years) participated in three separate trials of 40 min in random order and on different days: (1) resting and sitting on a comfortable chair, as a control (CON); (2) aerobic mock gardening activity exercise for upper limbs (UE); (3) aerobic cycling exercise for lower limbs (LE). Both exercises were performed at the same heart rate levels (target heart rate: 117 ± 17 beats/min), as determined beforehand by a pretest for each participant. Before (Pre) and after (Post) the exercises, heart-brachial PWV (hbPWV), which reflects arterial stiffness of the upper limbs from the aorta to the brachium; brachial-ankle PWV (baPWV), which reflects arterial stiffness of central (large arteries in the cardiothoracic region) and leg from the femoral to the ankle; and heart-ankle PWV (haPWV), which reflects systemic arterial stiffness, were measured as an index of segmental arterial stiffness.

RESULTS: No significant differences in baseline parameters were observed among trials. After the exercise, hbPWV significantly reduced in both UE (-11.4 ± 9.7%) and LE (-6.6 ± 8.1%) trials, but did not in CON (5.1 ± 6.0%) trials. On the other hand, interestingly, baPWV was significantly reduced only in the LE (-2.9 ± 5.2%) trials. In addition, baPWV in UE (3.1 ± 5.6%) trials significantly increased after exercise regardless of no significant changes in CON (1.8 ± 4.6%) trials. Finally, haPWV significantly reduced in both UE (-5.0 ± 5.7%) and LE (-4.7 ± 6.1%) trials, but did not in CON (3.4 ± 3.6%) trials.

CONCLUSION: Therefore, our data indicate that cycling exercise for lower limbs induces reductions in relatively systemic arterial stiffness (i.e., exercise-related direct and indirect regions). However, the influences of upper limb exercise on arterial stiffness are relatively limited and have a strong locality.

EFFECTS OF NOS3 GENE POLYMORPHISM ON CARDIO-ANKLE VASCULAR INDEX AS AN INDEX OF ARTERIAL STIFFNESS

YASUI, T., OI, N., TAGA, K., KUME, D., OKUDA-ASHITAKA, E., NISHIWAKI, M.
OSAKA INSTITUTE OF TECHNOLOGY

INTRODUCTION: Endothelial nitric oxide synthase 3 (NOS3) is involved in the production of nitric oxide (NO) in the endothelium, and the NOS3 gene polymorphism T-786C (rs2070744) is reported to reduce NOS3 promoter activity by mutation. However, in the general population, the effects of NOS3 gene polymorphisms on arterial stiffness using the Cardio-Ankle Vascular Index (CAVI), which is theoretically adjusted by blood pressure, have not been reported. This study thus aimed to examine the effect of the T-786C (rs2070744) gene polymorphisms on CAVI.

METHODS: Saliva sampling, CAVI assessment, and physical tests were conducted on 217 Japanese adult participants (18-84 years). DNA was extracted from saliva, and T-786C polymorphism (rs2070744) was screened using a TaqMan allelic discrimination assay. The subjects were also divided into three groups according to age: 122 young (18-37 years), 46 middle-aged (38-57 years), and 49 elderly (58 years and older).

RESULTS: In the Japanese group, the frequency of NOS3 gene polymorphism rs2070744 was TT type in 184 participants (84.8%), TC type in 30 participants (13.8%), and CC type in 3 participants (1.4%). No significant differences in CAVI value were observed between TT and TC+CC. However, the CAVI value tends to be higher in TC+CC than in TT (TT young: 6.0 ± 0.1 unit, TC+CC young: 6.0 ± 0.1 unit, TT middle-aged: 7.3 ± 0.1 unit, TC+CC middle-aged: 7.6 ± 0.2 unit, TT elderly: 9.0 ± 0.2 unit, TC+CC elderly: 9.3 ± 0.2 unit; Two-way ANOVA indicates Factor of Polymorphism: $P = 0.2132$, Factor of Age: $P < 0.001$, and Interaction: $P = 0.5675$).

CONCLUSION: These findings indicate that the tendency towards higher CAVI is found due to the mutations, but the gene polymorphism in NOS3 could not significantly affect age-related increases in arterial stiffness as assessed by CAVI in the Japanese general group, suggesting that the impacts of gene polymorphism in NOS3 may be a lesser magnitude compared to the polymorphism of monogenic disorders.

INCREASED ARTERIAL STIFFNESS GRADIENT IN BADMINTON PLAYERS WITH DOMINANT UNILATERAL ARM MOVEMENTS IS DIFFERENT FROM THE INCREASE IN ARTERIAL STIFFNESS GRADIENT WITH ADVANCING AGE

KIM, D.Y., LEE, R., HWANG, M.
INCHEON NATIONAL UNIVERSITY

INTRODUCTION: Pulse wave velocity (PWV), a validated measure of arterial stiffness, is a clinical indicator for cardiovascular disease risk. Arterial stiffness gradient, a novel marker of cardiovascular morbidity and mortality, is the ratio of central (aortic or carotid to femoral, cf) PWV to peripheral (arm or leg) PWV. Increased central arterial stiffness is a negative feature seen in the aged vasculatures. Regular physical activity reduces central arterial stiffness in various populations including the aged adults and chronic disease patients. But its effect on peripheral PWV is still controversial. In addition, to date, few studies have investigated changes in peripheral PWV in response to unilateral exercise, and no studies have investigated changes in arterial stiffness gradient. Therefore, the purpose of this study was to compare the differences in arterial stiffness gradient as well as to analyze the difference in armPWV between both arms according to the degree of unilateral arm exercise participation.

METHODS: Twenty-six young women participated in this study; eight elite-level badminton players (ELIT), ten club-level badminton players (CLUB), and eight age-matched sedentary participants (CONT). Central blood pressure and carotid-femoral PWV (cfPWV) as the central artery stiffness were measured using SphygmoCor Xcel system. Brachial-radial PWV (armPWV) as the peripheral stiffness was measured using Doppler Flowmeters and the associated data was collected and analyzed by PowerLab data acquisition system including Labchart Pro V8 software. Arterial stiffness gradient was calculated as the ratio of cfPWV to armPWV at both dominant and non-dominant arm, respectively. Body composition was assessed by using a segmental bioelectrical impedance analyzer.

RESULTS: In the dominant arm, the arterial stiffness gradient of ELIT and CLUB were significantly higher than CONT (0.73 vs. 0.46, ELIT vs. CONT, $P<0.001$; 0.59 vs. 0.46, CLUB vs. CONT, $P=0.04$). The arterial stiffness gradient of ELIT was also significantly higher than CLUB (0.73 vs. 0.59, ELIT vs. CLUB, $P=0.03$).

In the non-dominant arm, the arterial stiffness gradient of ELIT was significantly higher than CONT (ELIT: 0.59 vs. CON: 0.44 $P= 0.01$), but there was no significant difference between ELIT and CLUB, and CLUB and CONT (0.59 vs. 0.53, ELIT vs. CLUB, $P=0.36$; 0.53 vs. 0.44, CLUB vs. CONT, $P=0.09$).

The dominant and non-dominant armPWV were positively correlated with cfPWV and central blood pressures ($r\geq0.41$, $P\leq0.04$). The dominant and non-dominant armPWV were also inversely associated with the dominant arm muscle mass and whole-body muscle mass ($r\leq-0.49$, $P\leq0.01$).

CONCLUSION: The more unilateral exercise accumulated in the dominant arm, the higher the arterial stiffness gradient. Since the increased arterial stiffness gradient in active young adults is caused by decreased armPWV rather than increased cfPWV, an increase in arterial stiffness gradient may be associated with a reduced cardiovascular disease risk in the future.

CARDIAC DIFFERENCES BETWEEN PHYSICALLY ACTIVE AND NON-ACTIVE HYPERTENSIVE AND NORMOTENSIVE OLDS

KNEFFEL, ZS., PAVLIK, G., TÓTH, M., RADÁK, ZS.
HUNGARIAN UNIVERSITY OF SPORTS SCIENCE

INTRODUCTION: Hypertension is one of the most frequent diseases, approximately 40% of the adult population is involved, in the older adults its incidence is even higher, nearly 70%-80%. It is responsible for more than 50% of the risk factors of cardiovascular diseases, such as stroke, atherosclerosis and coronary diseases. With aging, either with or without hypertension, the cardiac condition becomes impaired; its main manifestation is left ventricular (LV) hypertrophy and a worsened function. Regular physical training is recognized for its positive impact on both hypertension and age-related cardiac issues. Given the limited research on older individuals with hypertension, this study aimed to focus on the cardiac advantages of an active lifestyle in this specific population.

METHODS: Cardiac morphology and function in 199 normotensive (NT) and hypertensive (HT), active and sedentary individuals, (male, n=111), were assessed at age >60 yrs. Echocardiography was performed in all subjects including two-dimensional guided M-mode, Doppler- and tissue Doppler measurements. Results were compared either by ANOVA, or by Kruskall-Wallis test.

RESULTS: LVM was referred to the body dimension by an index in which the exponent of the numerator and denominator is matched. Left ventricular muscle index (LVMI), is higher in active young than in sedentary ones, in our sample this variable was smaller in actives except in HT females (male NT: 82.9 vs. 98.3 g/m3; HT: 87.7 vs. 107 g/m3; female NT: 76.7 vs. 89.1 g/m3, HT:80.6 vs.91). Diastolic function was better in the following active groups (male, NT: 1.03 vs. 0.76, HT: 0.98 vs. 0.77 ns; female, NT: 1.21 vs. 0.9, HT: 1.04 vs. 0.88). Tissue Doppler results were also better in the active groups.

CONCLUSION: Our results indicates that at the older age the LV hypertrophy, which is a characteristic of the athlete's heart at the young age, becomes inverted between active and sedentary groups indicating that active lifestyle can prevent pathologic LV hypertrophy. The diastolic function, was also better in the active groups, the difference between the active and sedentary groups was more marked in the normotensive male groups than in the hypertensive ones.

ACUTE EFFECTS OF HIGH-INTENSITY INTERVAL EXERCISE DURING DIFFERENT MENSTRUAL STAGES ON PULSE WAVE VELOCITY AND BLOOD PRESSURE

YU, T.A.1, WANG, C.W.2, CHEN, L.Y.1, WANG, C.K.3, FANG, S.H.2, WANG, S.C.1, HE, C.S.1

1 NATIONAL CHUNG CHENG UNI, CHIAYI COUNTY, TAIWAN, 2 NATIONAL TAIWAN UNI OF SPORT, TAICHUNG CITY, TAIWAN 3 GRADUATE INSTITUTE OF EDUCATION NATIONAL CHUNG CHENG UNI, CHIAYI COUNTY, TAIWAN

INTRODUCTION: High-Intensity Interval Exercise (HIIE) has been proven to have positive effects on improving cardiovascular function (1). However, disparities in arterial stiffness improvement may exist among premenopausal women in different menstrual phases (2). Therefore, this study aimed to investigate the acute effects of HIIE on cardiovascular function in healthy young women during different menstrual phases, aiming to clarify the benefits on cardiovascular function.

METHODS: Thirteen female college students with regular exercise habits were recruited, and their menstrual cycle status was determined through a menstrual cycle questionnaire. One week before formal HIIE, the participants peak heart rate (HRpeak) was measured. Subsequently, one HIIE session was conducted during both the follicular and luteal phases of the same menstrual cycle. Each session comprised 10 sets of 1-minute exercise at 90% HRpeak intensity with 1-minute rest intervals. Blood pressure and finger-toe pulse wave velocity (ftPWV) were measured at Rest, immediately post-exercise (T0), and at 15 (T15), 30 (T30), 45 (T45), and 60 (T60) minutes post-exercise. Repeated-measures two-factor analysis of variance was employed for statistical analysis.

RESULTS: ftPWV at Rest, T0, T15, and T30 was significantly lower in the luteal phase group compared to the follicular phase group ($p < 0.05$). Systolic blood pressure (SBP) at Rest was significantly lower in the luteal phase group ($p < 0.05$), while the follicular phase group showed a significant decrease in SBP at T30, T45, and T60 compared to Rest ($p < 0.05$). Diastolic blood pressure (DBP) at Rest, T30, T45, and T60 was significantly lower in the luteal phase group ($p < 0.05$). The area under the curve (AUC) of ftPWV, AUC SBP, and AUC DBP during Rest-T0 was significantly lower in the luteal phase group ($p < 0.05$).

CONCLUSION: The acute effects of HIIE vary among different population groups. In healthy young women, cardiovascular stability is observed in the luteal phase following HIIE, potentially associated with elevated estrogen levels, suggesting a lower cardiovascular risk. Conversely, despite poorer vascular function, the follicular phase exhibits a significant decrease in SBP post-exercise, indicating a more pronounced vascular response, and implying a higher cardiovascular risk during HIIE in the follicular phase. Future exercise programs should consider the influence of different menstrual phases on vascular function to select appropriate exercise timing.

TONGUE'S THE WORD: EXERCISE TRAINING ALTERS THE NO2- PRODUCING MICROBIOME OF THE TONGUE DORSUM AND IMPACTS NO METABOLITE LEVELS IN SALIVA, SERUM, AND PLASMA.

SIMPSON, A., PILOTTO, A., BROCCA, L., MAZZOLARI, R., ROSIER, B., CARDA-DIÉGUEZ, M., CASAS-AGUSTENCH, P., BESCOS, R., PORCELLI, S., MIRA, A., EASTON, C., HENRIQUEZ, F., BURLEIGH, M.

UNIVERSITY OF THE WEST OF SCOTLAND

INTRODUCTION: Nitric oxide (NO) is a multifunctional signalling molecule, produced by NO synthase (NOS) enzymes or the stepwise reduction of nitrate (NO3-) to nitrite (NO2-) by commensal oral bacteria(1). Exercise training upregulates NOS expression, improving systemic health(2). Physical activity is also associated with oral health in the general population(3). This may be underpinned by actions of oral NO2- producing bacteria which increase oral resilience to acidification, preventing tooth demineralisation(4). We provide novel data exploring the effect of exercise training on the oral microbiome and NO metabolites.

METHODS: An exercise training and detraining study was used to explore changes to the oral microbiome and systemic and oral NO metabolite levels. Eleven untrained males (age 25±5 years, body mass 64.0±11.2kg, stature 171±6 cm, VO2peak<45ml·min−1·kg−1) underwent 8-weeks of high-intensity interval training (HIIT), followed by 12-weeks of detraining. Samples were collected at baseline, after training and after detraining. The tongue dorsum microbiome was examined using long-read 16S rRNA sequencing. Changes in NO3- and NO2-in saliva, serum and muscle were measured with high-performance liquid chromatography.

RESULTS: Multiple alterations were seen in the microbiome following changes in activity level (all p≤0.049). These changes were relevant to systemic and oral NO availability. At the genus level, post-HIIT, NO2producing Rothia and Prevotella increased in abundance and Neisseria decreased in abundance. Five of the nine species which increased in abundance post-HIIT demonstrate NO2producing capacity. These were Rothia mucilaginosa, Streptococcus salivarius, Streptococcus parasanguinis, Prevotella salivae and Prevotella melanginogenica. NO3- increased in plasma post-training (Δ 14.15, 95%CI 1.44-26.85uM, p≤0.03) and decreased post-detraining (Δ-9.91, 95%CI -1.10-18.73μM, p≤0.033). NO2- increased in saliva post-training (Δ+78.27, 95%CI 16.21-140.3μM p=0.016) but decreased in plasma (Δ-182.0, 95%CI -20.26343.7nM, p<0.029) and muscle (Δ-0.57, 95%CI -0.250.89 μMol.kg-1, p≤0.002), before returning to baseline post-detraining (both p≤0.011).

CONCLUSION: Structured exercise training altered the composition of the tongue dorsum microbiome, increasing the abundance of several NO2producing species. While NO3- levels in the muscle and saliva remained unchanged following HIIT, plasma NO3- increased. Exercise training also elevated salivary NO2- while decreasing NO2- levels in the plasma and muscle. These changes did not persist after detraining. When taken together, these results may have implications for general and oral health due to the potential impacts of oral NO2- production on NO availability.

HEART RATE VARIABILITY RESPONSE TO LOW-FREQUENCY SOUND VIBRATIONS IN REGULARLY ACTIVE MALE SUBJECTS

HAUSER, R., BESSON, C., GREMEAUX, V., DEGACHE, F.

CHUV: CENTRE HOSPITALIER UNIVERSITAIRE VAUDOIS

INTRODUCTION: Heart Rate Variability (HRV) exhibits a strong association with the autonomic nervous system (ANS) activity. In recent years, HRV has been used as an effective and reliable method of measurement to assess different fatigue status and recovery in athletes [1]. Low-frequency sound vibration (LFV) has been proved to increase the reactivity of cardiac vagal regulation and physical relaxation [2]. LFV is perceived through the auditory pathway and through skin mechanoreceptors. This study analyzed a unique pattern of LFV (RubesaSounds), which are highly structured and designed to create a neural saturation to enhance recovery. The aim of this study was to assess the acute effects of LFV on vagally-related HRV variables in regularly active male.

METHODS: 27 participants went through 2 different randomly chosen sessions in the exact same conditions. A conventional relaxation session (CRS) with no sounds nor vibrations and another LFV session. The LFV session consisted of 50 minutes of sounds (40-80Hz) inducing whole body vibrations. The duration of each session was 50 minutes. R-R intervals were collected in a supine position during the entire experience and lasted until 30 minutes post-session. HRV data was acquired using a heart rate monitor (Polar H10) and analyzed with Kubios Premium software.

RESULTS: A significant intervention effect (P=0.003) for HR between pre-session (63±8.5) and 30 minutes post-session (59.2±8.2) was observed in the LFV group only. Another significant intervention effect (p=0.035) was found in the ratio of low and high frequency powers in relation to heart rate ((LF+HF)/HR) which increased between pre-session (81.7±80.8) and 30 minutes post-session (135.1±130.3) in the LFV group only. No significant time effect was observed in RMSSD and LnRMSSD between pre- and post-30 in both groups. The recovery HRVs (between during and post-30) were significant in LFV for LnRMSSD (p=0.015), (LF+HF)/HR (p=0.007) and RMSSD (p=0.02) and non-significant in all variables for the CRS session.

CONCLUSION: This study was able to describe evidence of increased vagal tone post-intervention in LFV vs conventional relaxation session. A major finding of the study was a 1.5-fold increase in recovery speed compared to a conventional recovery session. Positively influencing vagal tone with LFV could offer a new perspective in sports-related recovery technologies. Our results are congruent with previous studies on the effect of vibrations on the ANS.

IMPACT OF A SCHOOL HEALTH EDUCATION PROGRAM ON PHYSICAL ACTIVITY AND FITNESS IN CHILDREN AGED 10 TO 13

BLACKBURN, P., LAROUCHE, A., PLOUFFE, J.

UNIVERSITÉ DU QUÉBEC À CHICOUTIMI

INTRODUCTION: School-based interventions combining nutritional education, physical activity, reduced sedentary activities and a behavioral management component have been reported to promote a healthy body weight, cardiometabolic health, and the acquisition of a healthy lifestyles. It also appears that school health education programs are associated with higher levels of physical activity and a better physical fitness among children. Interventions in which parents are involved also appear to be more effective than those performed without parents. Indeed, parents play an important role in acquiring a healthy lifestyle for their children, such as a balanced diet and a physically active lifestyle.

METHODS: Thirty-three children (6 boys / 27 girls) aged between 10 and 13 years were included in this study. They participated in two to three workshops per week for 25 weeks. One to two sessions were devoted to physical activity and the last weekly meeting was specific to nutrition. Anthropometric measurements and physical fitness were measured at the beginning as well as at the end of intervention.

RESULTS: Based on body mass index, our participants were not considered as overweight or obese. Furthermore, participants had a good perception of their sports skills. Indeed, participants indicated that they perceived themselves as having excellent or good sports skills. In terms of motivation, we asked the students what motivated them to be active. Here are the three reasons encouraging our participants to practice a sport or physical activity. These reasons remain similar from the beginning to the end of the program. The first motivation is to be in better shape (19 (70.3%) at the beginning and 21 (77.8%) at the end), the second is to maintain good health (19 (70.3%) at the beginning and 21 (77.8%) at the end), and the third motivation is to spend more time with their friends (15 (55.6%) at the beginning and 16 (59.3%)). During the intervention, participants reported more hours of moderate and high-intensity physical activity per week (+2.34 hours/week). However, this increase was not significant. We found a significant improvement in most of the physical tests performed during the study: grip strength (p=0.0015), seated sit-ups (p<0.0001), arm extensions (p<0.0001) and flexibility (p=0.0099).

Cardiorespiratory fitness, measured with the 20-m shuttle run, was also significantly improved during the intervention (p=0.0002).

CONCLUSION: This study demonstrates that a 25 weeks school intervention program is sufficient to improve physical fitness of children.

CP-MH09 Obesity/Weight loss/Elderly

EXAMINATION OF CUT–OFF VALUES FOR DETERMINING JAPANESE MALE UNIVERSITY ATHLETES WITH VISCERAL FAT OBESITY

TOMOMI, T.H., ASAKO, Z.M., YUKA, K., TOMOHIRO, K., SHUICHI, M.

JOSAI INTERNATIONAL UNIVERSITY

INTRODUCTION: Excessive visceral fat accumulation, which leads to lifestyle-related disease, causes the risk of cardiovascular disease. We have reported that approximately 40% of overweight Japanese male university athletes have a visceral fat area (VFA) ≥100 cm2, and the markers of liver function and lipid metabolism are higher than those of their peers with VFA < 100 cm2.

In Japan, visceral fat obesity is defined as VFA ≥100 cm2, and the cut-off value for determining visceral fat obesity is 85 cm in waist circumference (WC) for ordinary men. However, it is unknown whether it is appropriate to use WC as a criterion for determining visceral fat obesity in daily training athletes.

This study aimed to obtain cut-off values for determining visceral fat obesity in Japanese male University athletes.

METHODS: The participants were 200 male university athletes. Body measurements were taken in the early morning after an overnight fast. The body mass index (BMI) was calculated based on height and body weight. The VFA and WC were measured using abdominal bioelectrical impedance analysis (Panasonic, EW-FA90). Spearmans correlation analysis was used to examine the relationship between anthropometric parameters and VFA. Then, logistic regression analysis was performed with VFA ≥ 100 cm2 as the objective variable, and correlated anthropometric parameters as the explanatory variable. Furthermore, cut-off values were calculated using ROC curves.

RESULTS: Aged 18-24 years, the participants had a median (interquartile range) height of 175.3 cm (170.7 - 179.2 cm), body weight of 69.4kg (62.9 – 77.8 kg), BMI of 22.5 kg/m2 (21.0 – 24.9 kg/m2), VFA 44.0 cm2 (29.0 - 65.0 cm2) and WC 78.9cm (75.0 – 84.7cm). Those with VFA ≥ 100 cm2 accounted for 11.5% (23/200) among participants, with physical characteristics of height 176.9 cm (171.7 – 181.7 cm), body weight 99.0kg (89.3 – 103.9 kg), BMI 31.1 kg/m2 (30.1 – 32.2 kg/m2), VFA 122.5 cm2 (103.5 – 142.0 cm2) and WC 98.4 cm (93.9 – 103.8 cm). Positive correlations were found between VFA and body weight ($r = 0.851$, $p < 0.0001$), BMI ($r = 0.822$, $p < 0.0001$), and WC ($r = 0.937$, $p < 0.0001$), among which WC had the strongest correlations. Results of logistic regression analysis showed that the odds ratio (95% confidence interval) for body weight was 0.81 (0.59 - 1.10、$p = 0.172$), BMI was 1.88 (0.89 - 3.97、$p = 0.097$), and WC was 2.02 (1.13 - 3.62、$p < 0.05$), indicating WC was the only parameter associated to visceral fat obesity.

The area under the curve for WC 0.994 (0.987 - 1.00, $p < 0.001$) was the largest compared to body weight 0.977 (0.958 - 0.996、$p < 0.001$) and BMI 0.989 (0.978 - 1.00、$p < 0.001$). The cut-off values were body weight 82.7kg (sensitivity 95.7%, specificity 91.5%), BMI 26.4kg/m2 (95.7%, 93.8%), and WC 89.7cm (100%, 96.6%).

CONCLUSION: It is suggested that the cut-off value of WC for determining Japanese male university athletes with VFA ≥100 cm2 was 89.7 cm.

IS HIGH-INTENSITY INTERVAL TRAINING IN HYPOXIA MORE EFFECTIVE THAN IN NORMOXIA TO IMPROVE CARDIOMETABOLIC HEALTH IN SEDENTARY AND OVERWEIGHT/OBESE ADULTS? A META-ANALYSIS

DENG, S., YIN, M.1, CHEN, Z.1, GIRARD, O.2, LI, Y.1

1 SHANGHAI UNIVERSITY OF SPORT, SHANGHAI, CHINA; 2 UNIVERSITY OF WESTERN AUSTRALIA, PERTH, WA, AUSTRALIA

INTRODUCTION: Obesity is becoming a critical global public health concern [1]. Recently, high-intensity interval training in hypoxia (HIHT) has presented an innovative therapeutic approach to optimize fat loss strategies and mitigate cardiometabolic risks among inactive and obese populations [2, 3]. To date, currently available studies have produced mixed results [4]. This systematic review and meta-analysis aimed to determine the effects of HIHT compared with high-intensity interval training in normoxia (HINT) to improve cardiometabolic health outcomes in sedentary, overweight/obese adults.

METHODS: A systematic search was conducted on PubMed/MEDLINE, Web of Science, EBSCOhost, Embase, and Cochrane Library databases (up to January 2024) to identify original articles assessing cardiometabolic health outcomes in sedentary and overweight/obese adults following both HIHT and HINT. Subsequently, a meta-analysis was performed to determine the standardized mean difference (SMD) between the effects of HIHT and HINT on cardiometabolic health outcomes.

RESULTS: Eight studies with a total of 218 participants were included. HIHT induced greater improvement in maximal oxygen uptake (VO2max) (SMD = 0.53; 95% confidence interval [CI]: 0.22, 0.83; $I2 = 0\%$; $p < 0.001$) compared with HINT. There

were no significant differences in fat mass (SMD = -0.01; 95%CI: -0.42, 0.39), systolic blood pressure (SMD = -0.16; 95%CI: -0.54, 0.23), diastolic blood pressure (SMD = 0.02; 95%CI: -0.36, 0.41), triglycerides (SMD = -0.15; 95%CI: -0.45, 0.14), total cholesterol (SMD = 0.27; 95%CI: -0.03, 0.57), glucose (SMD = 0.06; 95%CI: -0.51, 0.64), as well as high-density (SMD = 0.20; 95%CI: -0.17, 0.56) and low-density lipoprotein cholesterol (SMD = 0.07; 95%CI: -0.30, 0.43) between HIHT and HINT.

CONCLUSION: Based on current evidence, HIHT induces greater VO2max improvements compared with HINT in sedentary and overweight/obese adults. However, due to the limited research, further investigation of this novel nonpharmacological therapeutic intervention is warranted with larger sizes, standardized protocols, and exploration of potential mediators (e.g., exercise intensity, hypoxic severity, sex, and age) to substantiate and expand the evidence across diverse populations.

PHYSICAL ACTIVITY LEVEL OF UNDERGRADUATE STUDENTS

GUERRIERO, M., BRUNO, A.3, MESSINA, G.4, MOSCATELLI, F.3, POLITO, R.1, DIPACE, A.3

1 UNIVERSITY OF FOGGIA, ITALY; 2 IUL TELEMATIC UNIVERSITY, FIRENZE, ITALY; 3 PEGASO TELEMATIC UNIVERSITY, NAPOLI, ITALY; 4 UNIVERSITY OF CAMPANIA

INTRODUCTION: The WHO emphasizes the value of regular exercise in preventing various health issues and enhancing general wellbeing [1]. Global recommendations regarding physical activity (PA) understood both as exercise but also as everyday moments involving movement or activity, agree in identifying at least 150 minutes per week of moderate to vigorous intensity exercise. The risk of incurring chronic diseases, for who meet or exceed these recommendations, is reduced by 20 to 30 per cent [2]. Sedentary lifestyles and low levels of PA are increasingly common in modern culture, and peaks are reached among young people, compared to children and adults, especially among university students away from home. The aim of this study was to investigate the habits and lifestyles among students living in ADISU-Puglia facilities, through the use of a questionnaire aimed at assessing how the choice to live away from home, impacted on their lifestyle and PA habits during a particular period of life.

METHODS: Eighty students, aged between 18 and 28, were recruited from ADISU Puglia (Agenzia per il Diritto allo Studio Universitario). The questionnaire was provided via Google Forms and accepted both multiple and open-ended responses. One of the researchers supervised the procedure. The variables were evaluated using descriptive statistics. The frequencies and distribution of the parameters sought were documented. Every participant gave written, informed consent prior to participation.

RESULTS: The results show the following: 1) 52.5% of the study subjects claimed to practice PA, while 38% claimed not to practice PA; 2) 45% of the students claimed not to practice any PA; 11.3% claimed to practice PA less than once a week; 6.3% claimed to practice PA one to two times a week; 25% claimed to practice PA two to three times a week; and 12.5% claimed to practice PA more than three times a week; Three points stand out in this survey: 3) 60% of the included students smoke; 4) non-smoking students claim to practice PA more than smoking students; 5) male students claim to practice PA more than female students.

CONCLUSION: The results show low levels of PA among students and habits such as smoking. This pilot study shows that, despite the limitations of this survey, research of this type is fundamental to carrying out actions to promote well-being among university students and their academic achievements, as well as becoming prevention tools among younger people.

THE EFFECT OF VOLUNTARY EXERCISE ON COLLEGE STUDENTS IN TAIWAN

CHUANG, Y.T., YANG, P.C., CHIU, Y.H., CHUANG, P.H., CHEN, I.T.

KAOHSIUNG MEDICAL UNIVERSITY

INTRODUCTION: In recent years, college students do not have enough time for exercise after class on Taiwan, resulting in a downward trend in physical fitness levels. Currently, there is no objective record and evaluation method for the analysis

of voluntary exercise performance on college students, and finding an exercise method that can improve physical fitness is an important issue. This study used wearable devices to collect data of voluntary exercise on college students, factor analysis was employed to extract a limited number of indexes factors from the parameters to analyze and identify objective exercise performance factors for college students. The developed indexes will be applied to a new voluntary exercise performance factor for voluntary exercise and physical education in physical fitness assessment.

METHODS: The 33 college students who completed the "100 Days and 100 Kilometers" running or brisk walking of exercise implementation plan; with pre and post running test, and voluntary running group activities once every week; the total 824 exercise data were selected for analysis; factor analysis was employed to extract a limited number of factors from the parameters to analyze and identify objective exercise performance factors.

RESULTS: 1. The The endurance fitness has improved on male and female college students who completed the "100 Days and 100 K" goal; 2. The "new voluntary exercise performance factors" extracted through factor analysis namely "exercise volume capacity", "exercise speed capability" and "exercise intensity", and based on this, a "sports performance radar chart" is constructed which can provide comprehensive performance evaluation; 3. For regular exercisers, the performance of each factor in the exercise performance radar chart is better than or equal to the mean value; 4. Group running activities can effectively to help students maintain the amount of exercise and intensity.

CONCLUSION: Promoting voluntary exercise implementation plan can effectively improve their endurance fitness level on college students; regular exercisers and those participating in running group activities can maintain a certain amount of exercise, speed and intensity; this study used wearable devices and the exercise record data to constructed exercise performance radar chart which can obtain comprehensive exercise performance results, and the developed new voluntary exercise performance factors for college students are feasible.

RISK FACTORS FOR SUDDEN CARDIAC DEATH DURING RACING IN JAPANESE THOROUGHBRED RACEHORSES

SUGIYAMA, F., MUKAI, K., TAKAHASHI, Y., EBISUDA, Y., YOSHIDA, T.

JAPAN RACING ASSOCIATION

INTRODUCTION: Thoroughbred flat races involve distances of 1,000-2,600 m and an approximate speed of 60 km/h, such that they are completed in only 1-3 minutes. Similar to human athletes, sudden cardiac death (SCD) has been reported in Thoroughbred racehorses, and it is one of the most common causes of fatality during races, second only to musculoskeletal disorders. Previous studies have identified some risk factors for SCD, such as age and season, whereas the results regarding other potential factors, such as race distance, have been conflicting (1, 2). Given the variation in horse populations and racing systems among horse-racing jurisdictions, individual assessments of these risk factors for SCD are essential. However, there have been no studies of the risk factors for SCD in Japan. Therefore, we aimed to analyze the incidences of SCD and the associated risk factors in Japanese Thoroughbred flat racing.

METHODS: Race information and the veterinary records for thoroughbred horses competing in flat races held by the Japan Racing Association (JRA) between 2001 and 2022 were collected from the official database, and a retrospective unmatched case-control study was conducted to identify the risk factors for SCD. Horses that were diagnosed with "acute heart failure" or "heart failure" at JRA racecourses were defined as SCD cases, whereas horses that were not were regarded as controls. Age, sex, body weight, track condition, surface type, race class, race distance, season, and training center were included as variables in the analysis. Variables were initially analyzed by a combination of forward- and backward-stepwise procedures and were included in the final model if $P \leq 0.2$. Multivariable logistic regression analysis was then performed to identify the risk factors for SCD, and variables with $P < 0.05$ were considered to be statistically significant.

RESULTS: During the study period, data for 1,039,096 race starts were extracted, and 81 cases of SCD were identified (prevalence 0.006%). Of the nine variables considered, five were included in the final model. Body weight was significantly associated with SCD ($P = 0.047$), but age ($P = 0.051$), race class ($P = 0.069$), sex ($P = 0.141$), and surface type ($P = 0.146$) were not. Compared with horses weighing ≤ 449 kg, the odds ratio for SCD for horses weighing ≥ 490 kg was 2.33 (95% confidence interval 1.08-5.05).

CONCLUSION: In Japan, the incidence of SCD during flat races is comparable to that previously reported (1, 3). In contrast to previous studies (3, 4), age and race distance were not found to be significant risk factors for SCD. However, body weight was significantly associated with SCD, which may provide a novel perspective regarding the etiology of SCD in Thoroughbred racehorses.

EFFECT OF EXERCISE INTENSITY RELATIVE TO THE VENTILATORY THRESHOLD ON AFFECTIVE RESPONSES DURING EXERCISE: A SYSTEMATIC REVIEW AND META-ANALYSIS

KINGHORN, D., PAVAL, D.R., GALLAGHER, I.J., VOLLAARD, N.B.J.
THE UNIVERSITY OF STIRLING

INTRODUCTION: Affective valence (AV; i.e., feelings of pleasure (positive affect) or displeasure (negative affect)) can be modified by exercise. Whether exercise makes someone feel 'good' or 'bad' may influence exercise enjoyment, and subsequently the uptake of, and adherence to, exercise routines. The dual-mode theory (DMT; Ekkekakis et al., 2008) proposes a homogenous increase in affective valence during exercise at intensities below the ventilatory threshold (VT), and a decreasing level of pleasure above the VT. This has led to an increase in studies investigating the effect of exercise at intensities prescribed relative to the VT on AV. The aim of the present study was to analyse the relationship between exercise intensity relative to the VT and the change in affective valence during exercise.

METHODS: A systematic review and meta-analysis (PROSPERO ID: CRD42022331507) was performed according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). The databases PubMed, Web of Science, Scopus and PsycInfo were searched up to August 2022 for the 4 possible combinations of the search terms "affective valence" OR "feeling scale" AND "ventilatory threshold" OR "lactate threshold". Studies were eligible if they investigated affective responses to exercise in apparently healthy adults with intensities set relative to the VT or lactate threshold (LT). Bayesian meta-analysis using linear and non-linear modelling was conducted to examine the relationship between exercise intensity relative to the VT and the greatest change in affective valence from baseline (pre-exercise) to any time points during exercise. Studies missing baseline affect data and trials implementing interventions in addition to exercise were excluded.

RESULTS: The search yielded 18 trials, involving n=533 participants, and exercise intensities equivalent to 80-110% of VT. Four of eight trials at intensities ranging from 80% to 96% of VT, four of five trials at 100% of VT, and all trials at intensities >100% of VT resulted in decreases in affective valence. Meta-regression analysis demonstrated a considerable effect of exercise intensity (effect size=1.41, 95% highest density interval (HDI): 0.41-2.39). No meaningful moderating effects of age, sex, BMI, and VO2max were observed at 95% HDI. The DMT proposes a non-linear relation between exercise intensity and the change in AV during exercise, but over the (limited) range of intensities in the available trials, the best fitting non-linear model was not superior to a linear model.

CONCLUSION: Although the analysis provides some support for the role of the VT as a turning point for changes in AV during exercise, there was no evidence for a homogenous positive response at intensities at or below the VT. Future research should identify factors explaining the variance in the change in affective valence during exercise at intensities at or below the VT.

ADHERENCE TO, AND SATISFACTION WITH, BALLISTIC RESISTANCE TRAINING VERSUS CONVENTIONAL RESISTANCE TRAINING: FINDINGS FROM THE REPROOF STUDY

BROOKE-WAVELL, K., MARQUES, E.A., CALISKAN, O., FOLLAND, J.P.
LOUGHBOROUGH UNIVERSITY

INTRODUCTION: Resistance training (RT) has been endorsed as a key component in the prevention and management of osteoporosis and osteoarthritis, both being prevalent in postmenopausal women. Both low-load ballistic (high-velocity, propulsive; BRT) and high-load conventional (low velocity) RT (CRT) are generally acknowledged as safe and effective in improving physical fitness outcomes in young adults. However, little is known about the feasibility of BRT in older populations. Assessing the adherence and satisfaction of postmenopausal women to this RT approach compared to CRT is thus crucial for understanding its acceptability and potential for wider implementation.

METHODS: The Resistance Exercise Programme on Risk of Osteoporosis and Osteoarthritis in Females (REPROOF) study was a randomised, three-arm intervention trial enrolling healthy postmenopausal women (mean age = 62.8 ± 3.8 years, mean BMI = 24.4 ± 3.4 years, with no recent RT participation), designed to compare the efficacy of BRT and CRT on several risk factors for osteoporosis and osteoarthritis relative to control. RT groups (38 BRT, 39 CRT) were prescribed similar training sessions (same exercises and repetitions, but different loads, velocities and ballistic intent) twice a week for 32 weeks. We assessed the retention rate and adherence to the RT programs via attendance records. Participants satisfaction was measured by questionnaire at the end of the study. Results are reported descriptively, and between-group comparisons of participants experiences were analysed using chi-square tests.

RESULTS: The same proportion of participants (74%) assigned to BRT and CRT completed the study (n=28 and n=29, respectively) and had a similar adherence rate of 98%, while 78% allocated to control completed the study (n=25). Overall satisfaction with the exercise programs was high and no differences were found between groups. Almost all participants (94.7%) would recommend the programme they completed to friends and family, and the endorsement was supported mainly by perceived health benefits (57.9%). Almost all participants in BRT and CRT enjoyed the sessions (96.4 vs 96.5%) and enjoyed exercising with other people (85.7 vs 96.6%). Similarly, they reported liking the exercise (100 vs 93%), feeling interested (89.3 vs 93.1%), feeling good physically while doing it (96.4 vs 89.7%), and that it gave them a strong sense of accomplishment (92.9 vs 96.6%).

CONCLUSION: These findings indicate that both BRT and CRT are feasible in a university research setting. Also, the success of a wider-scale application may benefit from considering some key aspects perceived by participants as positive such as

trained staff, one-to-one approach, flexible training schedule, and short sessions. The high intervention adherence and participant satisfaction suggest that a BRT is as acceptable and feasible as CRT in this population.

HEART RATE RESPONSE DURING MAXIMAL EXERCISE AND RECOVERY IS AFFECTED BY CHRONOLOGICAL AGE, AND NOT TRAINING AGE.

MELVIN, A., AUDET, A., NAAZ, S., KOZLOFF, K., LEPLEY, A.
UNIVERSITY OF MICHIGAN

INTRODUCTION: Habitual physical activity has numerous holistic benefits; however, some research suggests long-term participation in endurance exercise may lead to alterations in autonomic function. Existing research aiming to understand the relationship between endurance exercise exposure and heart rate control have focused primarily on older lifelong runners, elite athletes, and males. Evaluating the connection between cumulative years of regular endurance training (training age; TA) and heart rate (HR) response during and immediately following exercise provides an opportunity to understand autonomic control in a generalizable population of endurance exercisers. The purpose of this study was to determine if TA has an effect on HR response during exercise and recovery in healthy male and female endurance runners.

METHODS: 189 runners (94M, 95F; 35.9±12.1y; VO2max M: 51.9±8.8, F: 46.8±6.9ml/kg/min) training for an upcoming competition performed a graded maximal treadmill cardiopulmonary exercise test. Test protocol was dictated by self-selected half marathon race pace with 1kph increments every 3min until volitional fatigue. Metabolic data were collected breath-by-breath. HR at 10% increments of VO2max were calculated as five-breath moving averages corresponding to the first instance when five consecutive VO2 values met or exceeded the % value. Recovery HRs were recorded every min for 5min post-exercise. Participants self-reported TA and were grouped in 5y increments up to >20y. Pearson correlations assessed the relationships between chronological age (CA) and TA as continuous variables, with HR at each % VO2max and post-exercise HR recovery each min. Repeated measures ANCOVA (TA group x % VO2max stage) with CA as a covariate assessed the overall effect of TA on HR response at each stage during and after exercise.

RESULTS: CA and TA had significant, moderate negative correlations to HR at each stage (r^2 = -.17 to -.63, $p<.001$) and HR recovery at each min (r^2 = -.25 to -.49, $p<.001$). There was no significant interaction effect for TA group by stage ($p>.05$). A significant effect for stage showed that HR was different at all % VO2max and recovery intervals regardless of group ($p<.001$). There was a significant effect for group, where those with TA >20y had significantly lower HR than all other groups regardless of stage of exercise or recovery ($p<.05$), however the effect was insignificant when using CA as a covariate ($p=.95$).

CONCLUSION: CA is significantly related to lower HR at comparable workloads throughout an exercise test and recovery, regardless of TA. This suggests that autonomic HR control during and after exercise is driven more by CA than TA in a general healthy population of endurance runners.

This study received funding from Apple Inc. The funding source had no role in the analysis and interpretation of the data or in the submission of this abstract.

6-MONTHS MULTICOMPONENT TRAINING EFFECTS ON FUNCTIONAL CAPACITY, FRAILTY AND MUSCLE MASS IN SARCOPENIC AND NON-SARCOPENIC OLDER ADULTS.

VICENTE-RODRÍGUEZ, G., MORADELL FERNÁNDEZ, A., FERNÁNDEZ-GARCÍA, A.I., NAVARRETE-VILLANUEVA, D., SUBÍAS-PERIÉ, J., PÉREZ-GOMEZ, J., GONZALEZ-GROSS, M., ARA, I., CASAJÚS, J.A., GÓMEZ-CABELLO, A.
UNIVERSITY OF ZARAGOZA

INTRODUCTION: Sarcopenia and frailty are two geriatric syndromes that share the deterioration of functional capacity. Multicomponent training (MCT) appears to be an effective method for improving functional capacity, potentially serving as a tool for preventing and treating frailty and sarcopenia. The main aim was to evaluate the differences obtained by following a 6-month supervised MCT program in older adults at risk of sarcopenia and without sarcopenia in variables used to assess sarcopenia, functional capacity and frailty.

METHODS: A total of 66 older adults (80.4±5.6 y.) were conveniently divided into an intervention group (IG) and control group (CG) and were subdivided into two groups: at risk of sarcopenia (CG: N=11; IG: N=20) and no sarcopenia groups (CG: N=12; IG: N=23) according to the revised European consensus [1]. The IG underwent a supervised 6-month multicomponent exercise program, three days a week, while the CG continued with their usual activities. Skeletal muscle mass, handgrip strength, speed, and SPPB, Fried, and FTS-5 batteries were evaluated. A repeated measures ANOVA was conducted to study if there were significant changes after six months of training between groups (GxT) and within each group.

RESULTS: Those at risk of sarcopenia and without sarcopenia which belong to the intervention group show improvements in handgrip strength (from 15.7 ± 4.3 to 19.0 ± 4.4 kg and from 25.9 ± 9.0 to 27.9 ± 8.6 kg, respectively); walking speed (from 6.5 ± 2.1 to 4.4 ± 1.8 m/s and from 6.1 ± 3.9 to 4.4 ± 1.8 m/s, respectively); SPPB (from 7.2 ± 1.5 to 10.6 ± 1.7 and from 7.7 ± 1.4 to 11.1 ± 1.3 points, respectively); FTS-5 (from 21.7 ± 4.7 to 14.5 ± 6.2 and from 16.8 ± 5.5 to 11.5 ± 4.7 points, respectively) and Fried (from 1.7 ± 0.9 to 1.0 ± 0.8 and from 1.3 ± 1.1 to 0.7 ± 0.9 points, respectively) (all $p<0,05$). No GxT was observed when comparing these two groups, but it was observed for all these variables when compared to control and train pairs ($p<0,05$).

CONCLUSION: This MCT effectively enhances functional capacity and frailty in older adults with and without sarcopenia. However, further investigation is needed to determine if more specific exercise is required for skeletal muscle mass as those who improve muscle mass will probably improve their sarcopenic state.

STUDY OF THE CHANGES IN THE SALIVARY PROTEOME PROFILE BY OBESITY AND PHYSICAL ACTIVITY IN CHILDREN

HOMS AVILA, J., VASILEVA, F., CAZORLA-GONZÁLEZ, J., PLANS-SALAS, E., FONT-LLADÓ, R., PRATS-PUIG, A.
UNIVERSITY SCHOOL OF HEALTH AND SPORT, UNIVERSITY OF GIRONA

INTRODUCTION: Obesity is a complex and multifactorial chronic disease caused by the interaction between the genotype and the environment. A sedentary lifestyle in children can lead to a decrease in physical activity, which can contribute to the development of obesity and other health related problems such as cardiovascular diseases, metabolic syndrome, and type 2 diabetes. The World Health Organization (WHO) recommends that children and adolescents accumulate 60 minutes of moderate or vigorous physical activity (PA) per day (1), therefore regular PA during childhood is one of the most effective means of improving and preserve health.

Saliva offers a promising diagnostic alternative to detect inflammatory, metabolic and cardiovascular risk factors in pediatric populations. Saliva sample collection offers advantages such as being an easy and non-invasive technique. Therefore, the use of saliva as a diagnostic and prognostic fluid is of interest for childhood obesity research.

Our aim was to study whether obesity and physical activity can influence the salivary proteome.

METHODS: BMI was calculated as follows: (Weight (kg))/〖Height (m)〗^2. Age- and sex-adjusted standard deviation scores (SDS) for body mass, height and BMI were calculated using regional normative data. Participants were classified as underweight, normal weight, overweight or obese (2). Physical activity level (sedentary, light, moderate, moderate to vigorous, and vigorous) was assessed using the triaxial accelerometer that allows determining the quantity and quality of physical activity (Actigraph GT3X). Salivary proteome analysis was performed on 20 saliva samples [7.53±0.33 years; 56% girls] by MALDI-TOF mass spectrometry using the positive linear mode and a mass range of 5 to 20 KDa. Differences in mass spectra (MS) and peaks (m/z) were analyzed using the Mann-Whitney U test.

RESULTS: By comparing the proteome profiles in saliva of normal-weight and obese children, a total of 20 MS peaks with significant intensity differences ($p < 0.01$) were identified. When children meeting and not meeting physical activity recommendations were compared, 2 peaks were identified ($p < 0.05$).

CONCLUSION: These results suggest that both, obesity and physical activity can change the salivary proteome profile in children, which would allow the identification of core salivary proteins and the correlation of salivary levels of these core proteins with obesity, cardiovascular parameters and a healthy lifestyle in children.

PS-PL01 Mental health perspectives from the general population to elite level sport

PHYSICAL ACTIVITY AND EXERCISE FOR MENTAL HEALTH: HOW, WHY, AND IN WHOM?

HERRING, M.
UNI OF LIMERICK

Physical inactivity and mental illness are longstanding, interrelated global pandemics. Substantial evidence supports the prophylactic effects of regular physical activity and the efficacy of exercise for mental health, particularly anxiety and depression, across the lifespan in the general population. However, how, why, and in whom physical activity and exercise protect and improve mental health are less well known. Recent reviews from the World Health Organization Guidelines Development Group (DiPietro et al., 2021) revealed that knowledge on optimal/minimal physical activity dose has remained limited. Moreover, investigations of modifiable sources of variability in the physical activity—mental health relationship, which could prime or enhance implementation and benefits, are limited. For example, evidence of the efficacy of understudied exercise modes, including muscle-strengthening exercise, is comparatively scarce. To this end, Dr. Herring will discuss the protective associations of physical activity, including doses lower than those recommended for overall health, for mental health, effects of diverse modes of acute exercise and exercise training, particularly resistance exercise training, on mental health, and biopsychosocial factors that may predict/influence benefits of physical activity and exercise for mental health.

ELITE ATHLETES ARE HUMANS FIRST: THEIR MENTAL HEALTH CHALLENGES.

GOUTTEBARGE, V.

AMSTERDAM UNIVERSITY MEDICAL CENTERS

Mental health symptoms and disorders are common among elite athletes, may be induced by sport-related or environmental factors, and may impair performance. In June 2019, the International Olympic Committee (IOC) published its first consensus statement on mental health in elite athletes and created its Mental Health Working Group. These initiatives have been the foundation for prevention strategies that mitigate mental health symptoms and disorders in elite athletes. Prevention strategies include primary, secondary and tertiary prevention. This presentation touches the prevalence of mental health symptoms and disorders in elite sport, describes their contributing factors, stresses the importance of the prevention of mental health symptoms in athletes and introduces the various initiatives from the IOC Mental Health Working Group.

Invited Symposium

IS-PN04 Bone Health in Endurance Sports

EXERCISE FACTORS INFLUENCING THE BONE HEALTH OF ENDURANCE ATHLETES

SALE, C.
NOTTINGHAM TRENT UNIVERSITY

The career of competitive athletes is short, but it spans an important period for bone health, particularly in relation to the attainment of peak bone mass. For those athletes involved in high-intensity, high-impact activities, it is likely that involvement in their sport will positively influence their bone accrual during adolescence and early adulthood. The picture might not, however, be quite so positive for endurance athletes. Endurance athletes involved in both weight bearing sports, such as running, and non-weight-bearing sports, such as swimming and cycling, have been reported to have lower bone mass than other types of athlete or non-athletic controls. Although it is not necessarily straightforward to compare the bone health of athletes to population norms or even across sports, it is possible that the bone-loading characteristics and patterns experienced by endurance athletes during training and competition might place them at a relative disadvantage regarding their bone health. The major concern during the competitive years of an athlete is the potential for an increased risk of stress fracture injury, which can be significant injuries requiring a significant time off from training and competition. This is, of course, predominantly a concern for those athletes involved in weight bearing sports, since it is unusual to find large numbers of stress fracture injuries in non-weight-bearing sports, such as cycling and swimming. The major concern once an endurance athlete retires relates to an increased incidence of osteopenia and osteoporosis, which in turn increases the risk of fragility fracture occurrence. It is far from clear, however, whether the exercise training engaged in by endurance athletes during their competitive years significantly damages their bone health into later life in terms of an increased risk of these negative bone health outcomes. This talk will explore the relationship between the exercise factors, particularly in relation to loading characteristics, that might place different endurance athletes (e.g., distance runners, cyclists, swimmers, and triathletes) at an increased risk of poor bone health and its associated consequences. The talk will conclude by highlighting where future research efforts might best be employed to further our understanding of this vitally important issue for endurance athletes.

DIETARY FACTORS INFLUENCING THE BONE HEALTH OF ENDURANCE ATHLETES

DOLAN, E.
UNIVERSITY OF SAO PAULO

Bone is a nutritionally modulated tissue, requiring sufficient energy, macro and micro-nutrients for optimal metabolism, namely capacity to dynamically respond to fluctuating environmental demands, while simultaneously maintaining the structural integrity required to withstand habitual loading without injury. Endurance athletes face a number of challenges to meeting bone-specific nutritional requirements, which may contribute, at least in part, to the compromised bone health and high risk of bone injury reported for some groups of endurance athletes. Energy availability is a particular relevant issue to consider in this regard, given the high energetic demand of endurance training programs. Maintaining a lean phenotype is often considered desirable in many endurance sports, with athletes frequently restricting energy intake in an attempt to achieve or maintain a low body mass, further limiting the amount of energy available to support basic physiological processes, including bone metabolism. Low energy availability is often accompanied by an inadequate intake of macro and micro-nutrients that are key to bone health, including protein, carbohydrate and calcium. Furthermore, endurance exercise induces a range of acute metabolic perturbations, including to calcium, pH and redox status, all of which may increase bone catabolism and may potentially be counteracted with targeted nutritional strategies. This talk will summarize the bone-specific nutritional challenges that endurance athletes face, provide nutritional recommendations to support bone health in this group, and describe future research priorities within this area of investigation.

BREAKING MORE THAN RECORDS: BONE HEALTH IN ELITE CYCLING

VAN DIJK, J.
HAN UNIVERSITY OF APPLIED SCIENCES

Elite cycling, characterized by prolonged periods of low-impact activity in combination with high energy demands, presents unique challenges to maintaining bone health. This sport inherently lacks the high-impact mechanical loading found in weight-bearing activities, which is crucial for stimulating osteogenesis and preserving bone mineral density. Consequently, the skeletal system in cyclists is not subjected to the stresses that typically promote bone strength. Moreo-

ver, elite cyclists are prone to energy deficits due to the high energy demands of training and competition, often coupled with insufficient energy intake. This scenario can lead to a state of low energy availability, which may disrupt bone remodeling processes and accelerate bone loss. The interplay between suboptimal mechanical stress and inadequate dietary intake can thus create a perfect storm for bone deterioration, potentially heightening the risk of fractures during the career, and osteoporosis later in life. This presentation aims to dissect these intricate concerns and provide a blueprint for addressing them. The latest research on counteractive strategies will be presented, including nutritional strategies and exercise interventions to introduce necessary mechanical stimuli to the bones. Integrating these strategies will yield a framework aimed at preventing and addressing bone health issues among elite cyclists, with the dual benefit of not only extending their time in competition but also securing their bone health for life beyond their professional career.

IS-MH04 50 shades of adapted physical activity: Towards inclusive sport and exercise for all

HIGH INTENSITY ADAPTED PHYSICAL ACTIVITY FOR DIVERSE POPULATIONS, SUCH AS PEOPLE LIVING WITH CANCER OR DIABETES-2

KLAVINA, A.
LATVIAN ACADEMY OF SPORT EDUCATION

Positive effects from a healthy lifestyle are primarily derived from physical activity (PA), with secondary benefits encompassing psychosocial development and personal growth, along with a reduction of stress and unhealthy habits. While exercise statements have consistently recommended regular PA, the definition of health-promoting PA has shifted over time. Most PA guidelines recommend adults to engage in moderate-intensity aerobic physical activity (150 – 300 min), however, many health-related research studies have presented more beneficial effects of high intensity interval training (HIIT) in multiple patients' groups, including, breast cancer, type 2 diabetes, heart failure. Researchers play a crucial role in investigating the reliable potential of feasible and enjoyable high-intensity interval exercise (HIIT) interventions. This presentation aims to outline the evidence-based physiological, psychosocial health and quality of life benefits as a result from the HIIT interventions applied as part of health therapy programs. In addition, I will highlight the ecological model toward a healthier lifestyle as the rationale to demonstrate evidence-based examples of facilitating and limiting factors associated with technological innovations that may foster healthy lifestyle choices and well-being. I will elaborate on positive effects of HIIT on body mechanisms in people with cancer and using HIIT interventions to address cardiometabolic factors and quality of life in persons with type 2 diabetes (T2D). We have found that HIIT provides participants cardio-metabolic adaptations benefiting health and quality of life. Wearable technologies provide a promising opportunity to effectively assess functional capacities of the individual in an ecological environment. A major challenge is to apply innovative personalized technologies that can help individuals maintain healthy lifestyles and wellness by keeping track of their everyday activities in long term.

50 SHADES OF DATA USED IN ADAPTED PHYSICAL ACTIVITY

NG, K.
UNIVERSITY OF TURKU

Participants with specific impairments often do not meet the inclusion criteria in sport science studies. With an estimated 15% of the world's population living with disabilities, a sizable population where scientific knowledge is lacking. One of the challenges faced by researchers and practitioners is the awareness of how to identify people with disabilities in their own study. The aim of this presentation is to provide an overview of instruments used to measure various dimensions of adapted physical activity (APA), such as prevalence, functional and clinical tests. The individual's disability status can be captured through standardised self-report or proxy measures. Consistency between researchers during observations and classification tests is essential for understanding the range of movement, strength, and function in adapted physical activity. Furthermore, the boundaries in the use of technology to assist with data collection have been reduced since the COVID-19 pandemic, but may still exist in areas with low resources. Norms in functional tests, measured physical activity and overall movement could be inappropriate when participants have functional difficulties, and solutions to overcome these limitations are required. Despite these advances in understanding and measuring such dimensions, a myriad of ways to collect data is present in the field of adapted physical activity. This talk will go into a detailed review of the ways data is collected for prevalence rates, with emphasis on the Washington Group questions. The strengths and limitations of such methods are outlined. From the use of national datasets, a demonstration of the substantial changes to prevalence rates appears due to different cut-offs. Subsequently, selecting cut-offs has an important role when pooling data sets. Further discussions on what it means for data provision on adapted physical activity are brought up.

PHYSICAL ACTIVITY, EXERCISE AND SPORT IN PEOPLE WITH DISABILITIES AND/OR CHRONIC DISEASES

HETTINGA, F.

NORTHUMBRIA UNIVERSITY

People living with physical disabilities or chronic conditions experience many barriers to engage in physical activity. In particular in the period directly after rehabilitation discharge, we see that people struggle to integrate physical activity in their daily living. It is therefore that we started the Rehabilitation, Sport and Active Lifestyle (ReSpAct) research programme in 2012. This research programme aimed to use a prospective multi-center cohort study design to evaluate the nationwide implementation of the Rehabilitation, Sport and Exercise program (RSE, Dutch: 'Revalidatie, Sport en Bewegen') across eighteen rehabilitation centers/hospitals in the Netherlands. RSE is an evidence-based physical activity counselling programme involving multiple counselling sessions based on motivational interviewing during and after rehabilitation to stimulate a physically active lifestyle in adults with physical disabilities and/or chronic diseases. Since the start of ReSpAct in 2012, 14 publications have appeared providing insights into how we can optimize health and active lifestyle advice and support after rehabilitation discharge. I will shortly overview the main outcomes and highlight subsequent research we have conducted on physical activity and exercise in three particularly interesting populations in the field of adapted physical activity and sport: 1) wheelchair users, 2) people suffering from an invisible disability such as fatigue or pain and 3) people with intellectual disabilities.

BEYOND THE SURFACE: INVESTIGATING THE INFLUENCE OF BODY COMPOSITION AND ANATOMICAL FACTORS ON THE NUMBER OF IDENTIFIED MOTOR UNIT FROM HIGH-DENSITY SURFACE EMG RECORDINGS

SAMPIERI, A., SPINELLO, G., GOLDIN, E., MASARIN, A., FRANCHI, M.V., PAOLI, A., MORO, T., CASOLO, A.

UNIVERSITY OF PADUA, ITALY

INTRODUCTION: High-density surface EMG (HDsEMG) offers valuable non-invasive insights into individual motor unit (MU) activity and properties. However, large intersubject variability in the number of identified MU is often observed due to specific neural aspects and anatomical factors (e.g. volume conductor properties)1,2. A recent study3 on young males revealed that greater muscle electrode distance (MED), which includes skin, subcutaneous fat and superficial muscle aponeurosis, adversely affects HDsEMG signal decomposition in biceps brachii, especially at low force levels. Here, we investigated the influence of body composition and anatomical features on the number of identified MU in the human vastus lateralis (VL) muscle.

METHODS: To date, 48 healthy participants (17% female) representing two age categories (young adults (YG): 19-30 yr., elderly: 66-82 yr.) were enrolled in this study. They performed submaximal isometric knee extensions at 15%, 35%, 50%, and 70% of maximal voluntary contraction (MVC), while HDsEMG recorded the activity of the VL of the right leg (RL). HDsEMG signals were decomposed into individual MU for each force level. Multiple body composition features were evaluated using BIA and DXA, while ultrasonography (US) was used to measure MED precisely below the HDsEMG electrodes. Correlations and regression analyses were used to assess the relationships between the number of detected MU and body composition features according to force levels.

RESULTS: A total of 1476 unique MU were detected from the VL. Significantly negative correlations (Spearman's, $p<.05$ in all cases) were observed between MU number and fat mass (FM) estimated by BIA (15%: r=-.33; 50%: r=-.32; 70%: r=-.35) and DXA (15%: r=-.36; 35%: r=-.36; 50%: r=-.32; 70%: r=-.39), as well as FM RL estimated by DXA (15%: r=-.50; 35%: r=-.58; 50%: r=-.59; 70%: r=-.59), and MED (15%: r=-.69; 35%: r=-.72; 50%: r=-.72; 70%: r=-.72). Conversely, no associations were found between any other anthropometrical variable and the number of detected MU. When stratified by age group, simple linear regression analysis revealed that MED alone explained 79%, 66%, 61%, and 64% of the variance in the number of detected MU at 15%, 35%, 50%, and 70% MVC, respectively, in elderly, whereas 38%, 37%, 30%, and 32% at the same force levels in YG.

CONCLUSION: Our findings further confirm the influence of FM, and particularly MED (mainly composed of subcutaneous fat), on the quality of HDsEMG signal decomposition among healthy individuals with diverse characteristics. Specifically, greater body FM assessed by BIA and DXA were associated with decreased detectable MU. Notably, a more localized analysis of the anatomical area underlying HDsEMG electrodes enhanced the accuracy of MU number prediction. Our results highlight the importance of assessing MED using the US prior to HDsEMG recordings, as it emerges as the primary predictive parameter for MU number identification.

TENDON VIBRATION-INDUCED MUSCLE SPINDLE DESENSITIZATION DECREASES EFFORT PERCEPTION DURING CYCLING

MARCHAND, F., PAGEAUX, B., MONJO, F.

UNIVERSITÉ SAVOIE MONT-BLANC

INTRODUCTION: Effort perception is a major regulator of physical activity engagement and pacing strategies for endurance races [1,2]. In this framework, reducing effort perception during physical activity could be beneficial to both performance and physical activity engagement. A study has demonstrated that muscle spindles desensitization induced by a 10-min tendon vibration protocol reduces effort perception during subsequent isometric contractions of elbow flexors [3]. However, the effects of tendon vibration on effort perception during ecological tasks such as cycling remains to be explored. Therefore, the present study aims to assess the effects of tendon vibration on effort perception during cycling. We hypothesized that, for a same perceived effort, power output and vastus lateralis electrical activity would be higher after a tendon vibration protocol.

METHODS: Fifteen participants attended the laboratory for 2 experimental visits, involving Vibration and Sham Vibration conditions. In each visit, participants completed two 3-minute cycling bouts on an ergometer before (PRE) and two 3-minute bouts after (POST) a 10-minute tendon vibration protocol administered bilaterally to the patellar and Achilles tendons (100Hz frequency 1mm amplitude for Vibration; 15 Hz frequency 0.5mm amplitude for Sham Vibration). For each individual bout, participants were instructed to maintain a constant perceived effort level. Specifically, they pedaled at either a moderate (23) or a strong perceived effort level (50), as determined by the CR100 scale. Relative changes in power output and vastus lateralis electromyography (EMG) between PRE and POST were analyzed with a 2-Condition × 2-Intensity repeated analysis of variances (ANOVAs). Effect sizes were expressed as partial eta-squared and when ANOVAs were significant, Bonferroni post hoc tests were performed. Significance was set at $p < 0.05$.

RESULTS: For mean power output, the ANOVA revealed a significant main effect of the condition ($F = 20.8$; $p < 0.001$; $\eta 2p = 0.598$). Relative power output changes in the Vibration condition were positive (+18% at 23 and in +2% at 50) but were negative in the Sham vibration Condition (~-7% for both intensities). The ANOVA revealed similar outcomes for vastus lateralis EMG.

CONCLUSION: In line with our hypothesis, we found that power output and VL electrical activity increased after the ten-minute vibration protocol at controlled perceived effort intensities. This suggests that the desensitization of muscle spindles actually leads to a reduction in the perception of effort during submaximal cycling exercises.

EVENT-RELATED SPECTRAL DYNAMICS IN CENTRAL MOTOR AREAS DURING PASSIVE AND ACTIVE KNEE EXTENSIONS: AN EXPLORATORY EEG STUDY

VISSER, A., BÜCHEL, D., LEHMANN, T., BAUMEISTER, J.

UNIVERSITY OF PADERBORN

INTRODUCTION: Passive movement in early injury rehabilitation aims to increase the range of motion and restore capabilities for active movement control. Passive movement activates motor brain areas [1], which may address the neurophysiological deficits associated with joint injuries. Comparing passive and active movement could provide insights into how passive movement contributes to the recovery of active motor control. This study aimed to describe differences in spectral brain dynamics in central motor areas between passive and active knee extension using a mobile electroencephalography (EEG) approach.

METHODS: A total of 22 healthy participants performed knee extensions in passive and active manners. Each participant completed 10 blocks of 12 trials with a pause of 3 seconds before each extension. Torque and EEG oscillations were recorded during the experiment. EEG data was analyzed using independent component analysis to identify independent sources of brain activity. For investigating the effects of passive and active knee extension on motor brain activity, event-related spectral perturbations (ERSPs) in the fronto-central cluster were computed. Statistical comparisons were conducted using permutation-based analysis with false discovery rate correction ($p < 0.01$).

RESULTS: ERSPs in the central motor cluster revealed significant differences between passive and active knee extension before and during movement. While alpha desynchronization in the active condition started 500 ms before movement initiation, it started with a delay of 250 ms in the passive condition. In the theta frequency band, a significant increase in synchronization was observed immediately after movement onset (50 to 250 ms) in the passive compared to the active condition.

CONCLUSION: The results show differences in movement-related spectral brain dynamics between active and passive knee extension in healthy adults. Active movements elicit significant alpha desynchronization before movement onset, potentially linked to movement planning. In contrast, passive movements lead to an increased theta synchronization after movement onset, suggesting augmented sensory processing related to motor control [2]. Considering the different cortical

patterns of passive and active movement, further studies should look deeper into the functional relevance of passive movements in musculoskeletal rehabilitation.

STUDY ON THE MORPHOLOGICAL AND FUNCTIONAL PLASTICITY CHARACTERISTICS OF CEREBELLUM IN ATHLETES WITH DIFFERENT TRAINING YEARS

ZHANG, K., KAI, J., DONG, Z., CHUNMEI, C.

SOUTHEAST UNIVERSITY; CAPITAL UNIVERSITY OF PHYSICAL EDUCATION AND SPORTS;TSINGHUA UNIVERSITY

Introduction

It is widely accepted that consistent engagement in motor training leads to plasticity in the cerebellum, a region intricately associated with motor skill learning and motor control. Nonetheless, a lack of evidence currently exists regarding the patterns of cerebellar adaptations over a prolonged period of motor training.

Methods

A total of 142 physically active adults were recruited into this study. Based on the years of exercise training, they were divided into three groups, namely group 1 (n = 25, training for less than 1 year, 15M/10F, 20.0 ± 3.8 years old), group 2 (n = 43, training for 1-5 years, 31M/12F, 21.0 ± 2.6 years old) and group 3 (n = 74, training for over 6 years, 47M/27F, 20.9 ± 2.8 years old).

The brain imaging data were acquired using a Philips 3T scanner equipped with a 32-channel standard head coil. The T1 weighted image (T1WI) sequence was used to capture brain structure signals. In addition, echo planar imaging (EPI) sequence was utilized to obtain the resting state blood oxygen level dependent (BOLD)signal. Voxel-based morphometry analysis was conducted on T1WI images to evaluate the morphological plasticity, specifically the gray matter volume (GMV). Simultaneously, BOLD images were processed to obtain such as fractional amplitude of low-frequency fluctuations (fALFF), degree centrality (DC), and regional homogeneity (ReHo) for the assessment of functional plasticity characteristics.

In order to extract the signal values for GMV, fALFF, DC, and ReHo within the specified brain region, a cerebellum template was employed as a mask and applied to the whole brain signal maps. Subsequently, an analysis of covariance (ANCOVA) was conducted among the three groups, with gender and age serving as covariates in these statistical analyses.

Results

(1) As the years of training increase, the GMV shows an increasing trend. ANOVA indicated a main effect ($p \leq 0.001$) with significant interactions for GMV of both the left ($F(2,139) = 8.148$, $\eta 2 = 0.106$) and right ($F(2,139) = 7.979$, $\eta 2 = 0.104$) cerebellum.

(2) fALFF, DC, and ReHo exhibit a remarkable consistent trend: as the years of training increase, there is an initial rise followed by a subsequent decline. ANOVA indicated a main effect ($p \leq 0.05$) with significant interactions for both bilateral cerebellum in fALFF and DC (F left fALFF (2,139) = 3.798, $\eta 2 = 0.053$, F right fALFF (2,139) = 3.455, $\eta 2 = 0.048$, F left DC (2,139) = 3.998, $\eta 2 = 0.055$, F right DC (2,139) = 4.186, $\eta 2 = 0.058$).

Conclusion

With the increase in training year, cerebellum structural plasticity shows a continuous upward trend, while functional plasticity exhibits an initial positive change followed by a negative change. The current findings offer new insights into the adaptive responses of the central nervous system during different stages of motor skill learning.

INTERLIMB CROSS-EDUCATION EFFECTS OF MOTOR SKILLS IN THE LEFT-HANDERS.

ZHANG, W., WANG, Y., ZHAO, J., NAGATOMI, R.

TOHOKU UNIVERSITY

INTRODUCTION: The phenomenon of training one limb and improving the motor skills of both the trained and untrained contralateral limb is defined as cross-education. It was demonstrated that a cross-education effect of a finger-tapping task was only observed from the right dominant hand to the left non-dominant hand in the right-handers. Whether cross-education effect is also limited to the dominant hand training to non-dominant untrained hand in the left-handers is not determined.

METHODS: Left-hand (n = 24) dominant participants (age = 22.50 ± 6.56 years, male: female = 10:14) were asked to complete a set of finger-tapping training tasks (two digits with five fingers). 12 of them performed left-handed finger tapping training and 12 of them performed right-handed finger tapping training. The task consisted of both left- and right-handed tests before and after the experiment and ten trials of 2-min practice each on the same apparatus. The speed and task errors were measured and analyzed.

RESULTS: All subjects who trained either left hand or right hand improved their performance of the trained hand. The task correctness, and speed were improved for both trained and untrained hands, regardless of the side of training. The completion time of the tasks before training of the non-dominant right hand was 182.42 ±37.08 s and 136.56 ±26.00 s after

training, while that of non-trained left hand improved from 175.93 ±36.18 s to 118.45 ±42.75 s without training. The completion time of dominant left hand improved from 167.22 ±35.73 s to 130.03 ±27.33 s, while that of the non-trained right hand improved from 154.08 ±31.79 s to 118.54 ±21.66 s. A paired t-test revealed the improvements in both dominant to non-dominant, and non-dominant to dominant were statistically significant ($p < 0.05$).

CONCLUSION: Our results indicate that the interlimb transfer effect is also present in left-handed individuals, but from both dominant to non-dominant and non-dominant to dominant sides unlike the right-handed individuals.

OP-PN08 Nutrition IV

EFFECTS OF KETOGENIC DIET ON MUSCLE HYPERTROPHIC RESPONSE TO RESISTANCE EXERCISE

CERULLO, G., CHARRIER, D., CANATO, M., MORO, T., PAOLI, A.
UNIVERSITY OF PADUA DEPARTMENT OF BIOMEDICAL SCIENCES

INTRODUCTION: The ketogenic diet (KD) is a nutritional approach, commonly recognized for its efficacy in promoting fat loss, characterized by a high fat content, an adequate protein intake, and restricted carbohydrate consumption (<50 grams per day). However, the metabolic adaptations promoted by KD may potentially contrast with the pathways that regulate the hypertrophic response.

Indeed, the KD mimics several effects of caloric restriction by enhancing the activity of key factors involved in fat oxidation and oxidative phosphorylation. Among these factors, AMP-activated protein kinase (AMPK) stimulates mitochondrial activity while concurrently inhibiting the mechanistic target of rapamycin (mTOR), a critical regulator of protein synthesis.

In this regard, the aim of this study is to investigate the impact of the KD on the muscular response to resistance training in trained male subjects.

METHODS: Eight healthy trained male adults (29.9 ± 8.7 years) have been enrolled and randomly divided into a ketogenic diet (KD) or control diet (CD) group. Both diets were similar for energy (35 kcal/kg bw) and protein content (2 g/kg bw). All participants performed the same resistance training (RT) protocol for 4 weeks. Resting metabolic rate, body composition (Dual-energy X-ray absorptiometry), total body water (TBW via bioelectrical impedance analysis), quadriceps cross-sectional area via ultrasound and muscle strength were assessed at baseline and after 4 weeks of RT. In addition, muscle biopsies from the vastus lateralis were sampled at rest, 6 and 24 hours after a single bout of RT performed before and after 4 weeks of intervention. Histological data and phosphorylation of regulatory signaling proteins (i.e., mTOR, 4EBP1, and S6K) are under evaluation.

RESULTS: Preliminary data confirmed that participants in the KD group enhanced fat oxidation compared to the CD group (-12% vs. -6% mean decrease in respiratory ratio). Fat free mass was not significantly affected by the intervention in both groups. However, pronounced fat loss was reported in KD groups (-2,3 kg vs. +0,6 kg). In the KD group, a fluid loss was observed (-3% vs. 0% mean changes in TBW).

CONCLUSION: According to these preliminary results, KD seems to improve body composition without impacting gains in fat-free mass or muscle force. Further analysis of biopsies samples will show the effect of KD on histological parameters and hypertrophic signaling after RT.

EFFECTS OF EXOGENOUS KETOSIS ON MAXIMAL EXERCISE CAPACITY AND OXYGENATION FOLLOWING THREE-DAY HIGH-ALTITUDE RESIDENCE

TOMINEC, D., STALMANS, M., NARANG, B., MILLET, G.P., POFFÉ, C., DEBEVEC, T.
FACULTY OF SPORT, UNIVERSITY OF LJUBLJANA

INTRODUCTION: Altitude-related decrease in ambient pressure results in reduced oxygen availability for mitochondrial respiration. This leads to augmented physiological strain and decreased exercise capacity (1). To counteract this, ventilation, cardiac output, as well as muscle and lung blood perfusion are increased (2). However, even long-term acclimatisation at high altitudes does not fully counteract the negative effects of hypobaric hypoxia (2). Interestingly, we recently showed that elevating blood ketone bodies via oral ketone ester intake can attenuate the decline in blood and muscle oxygenation, while increasing oxygen uptake during submaximal cycling exercise at a simulated altitude of 2500–3000 m (3). In the present work we aimed to investigate whether ketone ester intake can attenuate the drop in blood and muscle oxygenation and subsequently alleviate the reduction of cycling exercise capacity during terrestrial high-altitude sojourn.

METHODS: Thirty-four participants (28 males, 6 females) underwent two experimental trials, one near sea level (295 m; Ljubljana, Slovenia) and one on the 3rd day of a high-altitude sojourn (3375 m; Torino hut, Aosta Valley, Italy). During the high-altitude sojourn, participants received, in randomized order, either a placebo (PLA group, n = 17) or ketone ester (KE group, n = 17) – with the aim to intermittently elevate blood ketone (e.g., D-ß-hydroxybutyrate ([ßHB])) levels to ~2–4 mM. Minute ventilation, oxygen uptake, systemic oxygen saturation and muscle tissue oxygenation, were continuously measured at rest, across submaximal work rates, and at peak exercise during the ramp-wise incremental cycling test (1 W

increment per 3 s) to volitional exhaustion. Independent t-tests with a Bonferroni correction were employed to evaluate differences between groups with significance set a-priori at $p < 0.05$.

RESULTS: KE ingestion resulted in stable ketosis (blood [ßHB] of ~2–4 mM in KE) at altitude, while blood [ßHB] remained low (~0.3 mM) in the PLA group ($p < 0.05$ for KE vs. PLA). No differences between groups were observed for hypoxia-related changes in oxygen uptake, systemic oxygen saturation and muscle tissue oxygenation or concomitant increase in minute ventilation at all relative power outputs. Also, no differences in altitude-related exercise capacity reduction were noted between groups (KE: Δ50 ± 16W vs. PLA: Δ53 ± 20 W, $p = 0.999$).

CONCLUSION: These data suggest that exogenous ketosis induced by ketone ester ingestion does not attenuate high-altitude related drop in blood and muscle oxygenation nor cycling exercise capacity.

EIGHT-HOUR TIME-RESTRICTED EATING WITH EXERCISE IMPROVES METABOLIC HEALTH IN ADULTS WITH CENTRAL OBESITY

ZHENG, C., CHEN, X.K., SUN, F.H., WONG, S.H.S.

THE EDUCATION UNIVERSITY OF HONG KONG

INTRODUCTION: Obesity is associated with several chronic diseases and has become a serious public health concern globally and also in Hong Kong. Time-restricted eating (TRE) is a popular dietary strategy as it only limits eating time without calorie restriction for weight loss. Both TRE and exercise have been examined as useful strategies to treat obesity-induced health problems, but there have been limited studies investigating the combined effect of TRE and exercise. Therefore, this study examined the effect of eight-hour TRE, with or without exercise, on metabolic health in adults with central obesity.

METHODS: This was a 16-week, four-arm randomized controlled trial. A total of 54 participants were randomly assigned to one of the four groups: control group (n=14), TRE group (n=14), exercise group (n=11), and TRE + exercise group (n=15). For the TRE group, participants could eat ad libitum in a self-selected eight-hour eating window with a 16-hour fasting period (allowed to consume water and no-calorie beverages). The exercise group was required to engage in 40 minutes of moderate exercise (55–70% of maximum heart rate) three times per week. Insulin, C-peptide, leptin, adiponectin, and resistin were measured using commercial ELISA kits. Linear mixed models with Bonferroni post-hoc comparisons were applied to examine the intervention effects.

RESULTS: All 54 male participants with central obesity (age = 35.8 ± 6.2 years) completed the 16-week intervention. The eating window was significantly reduced in the TRE and TRE + exercise groups after 16 weeks. All three intervention groups showed reductions in body weight, body mass index (BMI), and waist circumference after the intervention, while only the TRE + exercise group had lower measurements than the control group after the intervention (body weight = 91.3 ± 13.8 vs. 94.7 ± 15.3 kg, BMI = 30.4 ± 4.0 vs. 30.9 ± 4.1 kg/m2, waist circumference = 97.9 ± 9.2 vs. 103.4 ± 9.5 cm). Compared to the baseline, lower levels of glucose were observed in both the TRE (5.3 ± 0.5 mmol/L) and TRE + exercise groups (5.2 ± 0.3 mmol/L). After 16 weeks, reductions in leptin and resistin levels were found in all three intervention groups. However, only the leptin levels in the TRE + exercise group were lower than those in the control group (8.5 ± 4.6 vs. 10.6 ± 4.5 ng/ml) after 16 weeks. Furthermore, the decrease in insulin levels was only observed in the TRE + exercise group (12.8 ± 5.8 vs. 17.9 ± 9.3 mU/L), while no significant change in adiponectin.

CONCLUSION: Although all three interventions showed benefits in weight loss and improved metabolic health-related markers, the combination of TRE and exercise provided additional benefits. These results show that the combination of TRE and exercise may be useful in treating populations with central obesity and improving their metabolic health.

ASSESSING THE CONTRIBUTIONS OF TECHNICAL ERROR AND BIOLOGICAL VARIABILITY TO ERROR OF MEASUREMENT IN RELIABILITY STUDIES

PUEO, B., HOPKINS, W.G., JIMENEZ-OLMEDO, J.M.

UNIVERSITY OF ALICANTE

INTRODUCTION: A neglected issue in reliability studies is the separation of standard (typical) error of measurement into its two components: technical error arising from the measuring device, and biological variability arising from the subjects. Estimation of these components would allow evaluation of the devices performance independent of subject variability. Such estimation is possible when subjects are measured simultaneously with two different or identical devices, followed by analysis with a mixed model (1). We have now developed an alternative analysis implemented with a spreadsheet, which we have validated by simulation. We have also demonstrated its practical application to real data consisting of jump-height measurements.

METHODS: The basis of the spreadsheet is the analysis of the four pairs of change scores between the tests and devices. The standard deviations (SDs) representing technical errors and biological variability were derived with formulae in raw units, percent units (via log-transformation) and standardized units, and their confidence limits were derived with 1800

bootstrap samples (the maximum possible in the latest version of Excel). The spreadsheet analyses were reproduced in a SAS Studio program and compared with a mixed model. The program generated and analyzed 2000 datasets for chosen true (population) values of means and SDs simulating real data. These simulations allowed empirical derivation of factors to correct small-sample biases in the estimates of the SDs and in the coverage of their confidence intervals. For the practical application of the spreadsheet, 31 participants each performed two maximal countermovement jumps, with jump height measured simultaneously using a photoelectric system (Device A) and a jump mat (Device B).

RESULTS: The spreadsheet produced precise estimates and accurate confidence-interval coverage, outperforming the mixed model for sample sizes as low as 10. Analysis of the jump-height data revealed typical errors of 5.6% (90% confidence interval 4.5 to 6.8%) and 7.1% (5.7 to 8.6%) for Devices A and B respectively, which consisted of biological variability of 5.4% (4.1 to 6.8%) combined with technical errors of 1.4% (-2.1 to 2.9%) and 4.5% (3.5 to 5.4%) for Devices A and B respectively. Using standardization with an external SD of 10% to assess magnitudes, the technical error for Device A made negligible contribution to its typical error, while the differences in technical and typical errors between Devices B and A were moderate and likely substantial. There was negligible mean bias in Device B relative to A (-0.6%, -1.6 to 0.6%).

CONCLUSION: The spreadsheet provides accessible trustworthy analysis of reliability data taken simultaneously with two devices. The practical example highlights its relevance in contexts demanding precise measurement.

BIAS ARISING FROM PUBLICATION OF ONLY STATISTICALLY SIGNIFICANT EFFECTS ON ATHLETE ENDURANCE PERFORMANCE: QUANTIFICATION IN META-ANALYSES OF SIMULATED STUDIES

WIESINGER, H.P., HOPKINS, W.G.

PARACELSUS MEDICAL UNIVERSITY, SALZBURG

INTRODUCTION: The magnitude of an effect differs from sample to sample, owing to sampling variation. Larger effects are more likely to be statistically significant and published as important findings. Hence meta-analyzed magnitudes of published effects may suffer from substantial upward publication bias. Here we meta-analyzed simulated studies similar to those in recent meta-analyses of athlete performance to investigate such bias.

METHODS: We simulated effects on endurance time-trial performance in an intervention group by assuming true mean effects of 1.0% (trivial-small) on males and 3.0% (small-moderate) on females, heterogeneity SD (true between-study differences in the mean effect) of 0.0%, 0.5% (trivial-small) and 1.5% (small-moderate), standard errors of measurement of ~3.0% (range 1.5-6.0%), and sample sizes of ~13 (range 10-30). Meta-analyses were performed by excluding 0%, 100%, and 50% of non-significant effects. At least 10 studies were included in each meta-analysis. At least 2000 meta-analyses were performed for each combination of study characteristics, and meta-analyzed effects were averaged to determine bias (difference from true effects). We used a meta-regression mixed model that included a fixed effect for sex, its interaction with the square of the standard error (SE, to adjust for bias), and a random effect for heterogeneity. Mean effects not adjusted and adjusted for bias were those predicted for SE squared equal to its mean and zero, respectively.

RESULTS: The meta-analyses estimated mean effects and heterogeneity without bias when all non-significant effects were included. Complete exclusion of non-significant effects produced the greatest bias in mean effects when heterogeneity was moderate (males, +2.3%; females, +1.2%); adjustment for bias partially corrected the bias for males (to +1.2%) and almost fully corrected the bias for females (to +0.2%). Bias in mean effects was least when heterogeneity was zero (males, +1.5%; females +0.6%), and was almost fully corrected after adjustment (to +0.3% and -0.2%). Heterogeneity itself was underestimated by -0.8% for true moderate heterogeneity and by -0.2% for zero true heterogeneity. When 50% of non-significant effects were excluded, bias was reduced, but the correction for bias was largely ineffective, while heterogeneity was estimated without bias.

CONCLUSION: Publication bias is likely to be small in small meta-analyzed mean effects on athlete endurance performance, and bias will be negligible for large effects. Meta-analysts can improve adjustment for publication bias by using meta-regression to reduce heterogeneity. The problem of publication bias would be obviated if authors submitted, and journal editors accepted, manuscripts irrespective of statistical significance of effects. Meantime, the simulation program, and versions for standardized effects and risk ratios, can be adapted to estimate the bias in mean effects and heterogeneity with any meta-analyses in sport and exercise.

PLAYER UNDER PRESSURE PERFORMANCE ANALYSIS BASED ON TIME-SEQUENTIAL DATA AND GRAPH NEURAL NETWORK

PEI, Y., CHAOYI, G., JIAMING, N., VARUNA, S.

LOUGHBOROUGH UNIVERSITY - LONDON

INTRODUCTION: Sports performance analysis has been developed for decades, and essential metrics like passing rates and tackles have been used to evaluate players, while the context of these metrics is ignored. The key difference between an average player and a star player is how they handle pressure, make correct decisions and keep the same elite performance. Therefore, this study aims to quantify the pressure context for football players and analyse their performance under different pressure levels.

METHODS: Tracking and event datasets with broadcasting videos of 10 different Premier League matches have been used in this research. Tracking data records the x and y location of each player and the ball on the pitch at 25 Hz per second and the event dataset contains the on-ball events including passes, shots and tackles during the match. A Graph Neural Network (GNN) based sequential model is applied to predict whether the possession team is going to lose control of the ball under the opponent's pressure. A higher likelihood of losing control of the ball equals a higher level of pressure, and players' performance under different levels of pressure is then evaluated. Deep learning, GNN-based sequential model, 3D Human Body Estimation and Player Pressure Map (PPM) features were used to leverage the dataset and predict the outcome of football footage.

RESULTS: The purpose of this model is to predict whether the possession team will lose the ball control or not within seconds. The result is compared between various models and features. For the basic GNN model with only a tracking dataset, the prediction accuracy is 55.8%. By adding the 2D PPM features we generated, the accuracy increased to 75.2% and when the PPM features turned into 3D, the accuracy raised to 78.7%. By upgrading the model to a sequential GNN, the prediction accuracy with 3D PPM features reaches 81.2% which is the highest among all the experiments—both PPM features and time-sequential model help to improve the model accuracy massively.

CONCLUSION: The contribution of this pilot work was to quantify the pressure level based on the football context and time-sequential dataset with 3D human body pose. The work is aimed to represent the 3D football context and predict the pressure level of football matches. The pressure metric and context performance analysis are based on the prediction. In summary, PPM features and time-sequential dataset help to improve the model accuracy and lead the metric step forward.

ELEVATING PERFORMANCE: PREDICTING ALTITUDE TRAINING EFFECTS AND IDENTIFYING KEY VARIABLES FOR OPTIMAL ENDURANCE TRAINING

KRANZINGER, C., KRANZINGER, S.1, GLOMSER, G.2

1 SALZBURG RESEARCH FORSCHUNGSGESELLSCHAFT MBH; 2 GAIRRIT

INTRODUCTION: Predicting the individual effects of altitude training is of great interest in endurance sports. Estimating its potential effects results in more efficient training programme design. This study aims to investigate the possibility of predicting altitude training effects in terms of maximum increase in performance adaptation and identify key variables influencing the effectiveness of altitude training through a single performance test comprising two measurements at different altitudes using machine learning models.

METHODS: Data of 50 athletes were analyzed who underwent the same test protocol on a cycle ergometer under two simulated altitude conditions at 400 and three hours later at 1,800 m above sea level, respectively. The altitude was simulated in a mobile altitude chamber. Physical activity was measured with a spiroergometry system from CORTEX (CORTEX Biophysik GmbH, Germany). 21 parameters (covering aspects of eg.: heart rate, respiratory rate, oxygen saturation, fat metabolism) were used for the classification approach. The most important variables were determined by applying a recursive feature elimination algorithm, using a Random Forest and taking into account the out-of-bag error (Diaz-Uriarte & de Andrés, 2005). Three classes were predicted: low, medium, and high effect of altitude training. Various statistical estimation models were tested for the classification: Random Forest, AdaBoost.M1, Support Vector Machine and Naive Bayes. The validation was carried out with a leave-two-subjects-out cross-validation.

RESULTS: The best results were achieved with a Naive Bayes approach. The average classification accuracy across all 1,225 test data sets is 58.8% (sd: 0.34). In addition, an average Cohens kappa of 0.26 (sd: 0.49) is achieved. Examining the most important variables for classification, we find that the altitudes impact is most accurately predicted by the ratio of oxygen saturation during recovery to oxygen saturation during stress at 400 m and the ratio of respiratory rates during recovery to respiratory rates during stress at 1,800 m.

CONCLUSION: Following the framework of Landis and Koch (1977), the results of Cohens kappa show a "fair" classification performance. According to accuracy, the expected increase in performance through altitude training can be predicted for around six out of 10 athletes. The number of test subjects with the label "high" performance improvement through altitude training should be increased, as only four of the 50 athletes have this label, which makes it difficult to classify individuals with a high expected performance improvement through altitude training.

EXPLAINABLE ARTIFICIAL INTELLIGENCE MODEL FOR IDENTIFYING MARKET VALUE IN PROFESSIONAL SOCCER PLAYERS

ZHANG, S., LI, M.

TSINGHUA UNIVERSITY

INTRODUCTION: The realm of association football transcends the boundaries of sport, evolving into a significant business sector with player transfers being pivotal economic events. Consequently, determining the market value of football players is a critical managerial function. This research introduces an advanced machine learning technique to predict soccer players market values, integrating ensemble models with Shapley Additive Explanations (SHAP) to enhance interpretability.

METHODS: Leveraging data from Sofifa.com and transfermarkt.us recognized for its widespread use among FIFA football manager game fans, the study builds on prior research to perform a comprehensive analysis. The Boruta algorithm,

known for its efficacy in feature selection and implemented via the BorutaShap Python package, was employed to refine the set of player characteristics used in model training. An array of machine learning algorithms was scrutinized to develop an optimal model for appraising player market values including Adaboost, LightGBM, Random Forest, Gradient Boosting Decision Tree (GBDT), CatBoost, and XGBoost.

RESULTS: The initial dataset comprising 29 features was condensed to 22 salient features using the Boruta algorithm. In the quest to find the most accurate predictive model, the GBDT model exhibited exceptional performance. It achieved the highest R-Squared value of 0.889, indicating a strong correlation between the predicted values and actual market values. The subsequent models, CatBoost and LightGBM, displayed slightly lower but comparable R-Squared values. The GBDT models dominance extended to its predictive precision, reflected by the lowest Root Mean Squared Error (RMSE) across the algorithms, suggesting its forecasts were closest to the true player values. The robustness of the GBDT model was further confirmed on a separate test set, where it maintained the highest R-squared value of 0.901 and the lowest RMSE, underscoring its reliability in predicting player market values.

CONCLUSION: The Gradient Boosting Decision Tree (GBDT) model stood out as a superior predictive tool for estimating soccer players market values. The integration of SHAP for model interpretation identified nine crucial player attributes such as short passing, finishing, interceptions, dribbling, standing tackle, sprint speed, acceleration, and reactions that significantly influence market value predictions. These findings are invaluable for football team managers and stakeholders, providing a data-driven basis for transfer negotiations and strategic planning. The application of such advanced predictive analytics can revolutionize the economic aspect of player transfers, offering a more objective and nuanced understanding of player worth in the competitive football market.

OP-BM08 Jumping

SQUAT JUMP AND COUNTER-MOVEMENT JUMP CLUSTER ANALYSIS BASED ON SUBORDINATE GROUND REACTION FORCE VARIABLES

ŠARABON, N., KOZINC, Ž., SMAJLA, D.
UNIVERSITY OF PRIMORSKA

INTRODUCTION: Vertical jumps are among most represented sport performance tests. Ground reaction force derived metrics (e.g., force, power, and force impulse) are commonly analysed. Prior research has investigated how characteristics of force-time profiles (e.g., timing of peak force [1], number of force peaks [2]) influence performance. Although a connection between the characteristics of the force-time curve and jump effectiveness is indicated, the challenge of identifying the optimal force-time profile necessitates further investigation. The aim of this paper is to address this knowledge gap by applying clustering approach based on ground reaction force variables of squat jump (SJ) and counter-movement jump (CMJ) force-time signals.

METHODS: High-level athletes (basketball, soccer, tennis, long-distance running, dance, and martial arts; n=310)) participated. Three repetitions of SJ and CMJ were performed on Kistler force plate. K-means clustering method, that aims to partition n observations into k clusters in which each observation belongs to the cluster with the nearest mean, was applied to SJ and CMJ parameters. K-means clustering method was used to create 10 clusters, of which the 3 clusters with the highest representation were taken for further processing. Relative distances between cluster centres were calculated for each squat and countermovement jump parameter.

RESULTS: 809 SJs were taken into analysis. Three clusters with highest representation of jumps were: cluster 1 with 375 jumps, cluster 2 with 241 jumps and cluster 3 with 177 jumps. The four SJ parameters with the highest relative distance between cluster centres among the three clusters were: force impulse between maximal force and take off, start interval relative power, force impulse in the 2nd half of push off and start interval velocity.

841 CMJs were taken into analysis. Three clusters with highest representation of jumps were: cluster 1 with 290 jumps, cluster 2 with 277 jumps and cluster 3 with 249 jumps. The four CMJ parameters with the highest relative distance between cluster centres among the three clusters were: force impulse in the 2nd half of push off, push off force impulse, force impulse in the 1st half of push off, positive force impulse.

CONCLUSION: Results of this study demonstrate the grouping of vertical jump actions into force-time curve types that are distinct from one as reflected in more or less standard outcome metrics. This study is an entry step into quality of the SJ and CMJ ground reaction force curves with the ambition to upgrade applied value of this common athletic performance tests.

SHOULD ECCENTRIC UTILIZATION RATIO BE USED IN ASSESSMENT OF ATHLETES? A REPORT FROM A SERIES OF EXPLORATORY STUDIES

KOZINC, Ž., ŠARABON, N.

UNIVERSITY OF PRIMORSKA, FACULTY OF HEALTH SCIENCES, IZOLA

INTRODUCTION: The eccentric utilization ratio (EUR), defined as the difference between countermovement jump (CMJ) and squat jump (SJ) performance, has been traditionally linked to elastic energy use and stretch-shortening cycle efficiency [1]. However, recent theories suggest higher EUR may also reflect different factors, such as poor concentric rate of force development (RFD) [2], questioning its role as an indicator of athletic performance. The aim of this series of exploratory studies is to contribute to the understating of the mechanisms underlying the variation in the magnitude of the EUR.

METHODS: The paper presents a series of exploratory analyses based on data available from previous confirmatory studies and data from authors' database. In all cases, vertical jumps (CMJ and SJ) were performed on a Kistler force plate (model 9260AA6). Three repetitions of each jump with 1-min rests were performed with hands placed on the hips, and the repetition with best jump height was take for further analysis. Jump heights was calculated using take-off velocity method.

RESULTS: In the largest exploratory study, we compared EUR across 9 different sports (total n = 712), showing little difference between sports characterized by jumping (e.g., volleyball, basketball) and others. In the second analysis (n = 314; runners, basketball and soccer players) inverse correlations emerged between EUR and RFD in SJ ($r = –0.41$; $p < .001$), when the former was calculated based on force parameters. A third analysis (n = 45, volleyball) revealed that CMJ metrics exhibit larger correlation to performance proxies (sprint, agility and approach jump tests) than EUR.

CONCLUSION: The results of the presented exploratory analyses align with the current theory on mechanisms driving variations in EUR [2]. Greater height in CMJ is largely underpinned by the build-up of force and muscle activation during the countermovement. Our analysis suggests that the remaining variation in EUR among individuals may be explained by different factors, and that EUR is not necessarily linked to superior athletic performance. Notably, poor concentric RFD and lower muscle stiffness were suggested to be related to lower SJ performance, and consequently, higher EUR. However, it has to be stressed that further studies are needed to reach firmer conclusions, as our analysis were purely exploratory.

EFFECTS OF AN 8-WEEK JUMP TRAINING ON NEUROMUSCULAR AND CARDIORESPIRATORY FITNESS IN YOUNG HEALTHY NON-EXERCISING ADULTS

BARZYK, P., BIELEKE, M., ASSLÄNDER, L., SCHWENK, M., MORENO, M.M., SCHÜLER, J., GRUBER, M.

UNIVERSITY OF KONSTANZ: UNIVERSITAT KONSTANZ

INTRODUCTION: Physical inactivity has harmful effects on health and is therefore a major public concern. Recently, we were able to show that high-intensity jump training was able to counteract the detrimental effects of 60 days bedrest on muscle and strength losses as well as on declines in aerobic capacity (Kramer et al. 2017). Within the ProPELL (Promoting Physical Exercise in Lab & Life) research project, we now investigated the effects of eight weeks of high-intensity jump training in non-exercising healthy young adults (Bieleke et al., 2022). We hypothesized to find increases in neuromuscular and aerobic capacity in the training group compared to a non-exercising control group.

METHODS: Sixty-four young adults (34 female; mean age: 24.5 years, SD 3.5) were randomly assigned to either an eight-week high-intensity jump training or a control group. The training consisted of three weekly sessions of 15-minute high-intensity jump exercises aimed at improving neuromuscular and cardiovascular function. Pre and Post measurements included jump height and peak power during countermovement jumps, maximum isometric strength (leg extension in an isokinetic device), as well as maximum oxygen uptake (VO2peak) using a cycling spiroergometry protocol. We calculated ANOVAs (group * time) to analyze the data.

RESULTS: Training improved jump height from 36±16 cm to 38±17 cm compared to control (37±16 cm to 37±15 cm; $p<.001$, $d = 0.29$). VO2peak increased in both groups without an interaction effect (training group: 33.3±17.4 to 35.4±16.6 ml/min*kg, control: 30.7±15.6 to 31.8 ± 17.6 ml/min*kg; $p<.001$, $d = 0.9$). No differences were found for the peak power of countermovement jumps and isometric maximal voluntary contraction during leg extension.

CONCLUSION: A 15-minute jump training program three times a week increased jump-specific performance in a group of young healthy non-exercising adults. However, we did not find improvements in neuromuscular and cardiorespiratory fitness in this group. Since we have already shown such effects for jump training as a countermeasure to the detrimental effects of physical inactivity on neuromuscular and cardiorespiratory fitness (Kramer et al., 2017), we conclude that the "load" (intensity and volume) of jump training was not high enough in the present study to increase neuromuscular and cardiorespiratory fitness in healthy young adults.

ANGLE-SPECIFIC ANKLE JOINT TORQUE CONTRIBUTING TO THE DIFFERENCE IN COUNTER MOVEMENT JUMP PERFORMANCE

MACHIZUKA, S., JO, I., YOON, J., LEE, H.
YONSEI UNIVERSITY

INTRODUCTION: Counter movement jump (CMJ) is widely used to evaluate lower limb muscle performance. During the CMJ, the ankle plantar flexors are responsible for generating and maintaining concentric force until push-off (1). Considering the force-length relationship, the ankle joint becomes less capable of exerting force as it approaches maximum dorsiflexion. (over 25 degrees) (2). Therefore, the aim of this study is to identify the angle-specific ankle joint torque contributing to the difference in CMJ height between good jumpers (GJ) and bad jumpers (BJ).

METHODS: Fourteen male participants were divided into two groups based on their CMJ height: the GJ group with heights of 50cm or more, and the BJ group with heights of less than 50cm. The participants took part in an experiment consisting of sessions for measuring maximal CMJ height and maximum voluntary contractions (MVC) of isometric ankle torque, which were conducted using a dynamometer at five different angles (-15, 0, 10, 20, 25 degrees). Lower extremity joint kinematic and kinetic data were obtained using the musculoskeletal program (OpenSim4.1). Statistical analysis was conducted using independent t-tests.

RESULTS: Jump height (GJ: 54.0±3.2cm, BJ:45.7±3.6cm), peak GRF (GJ:2.5±0.1, BJ:2.2±0.2), and peak GRF after onset of ankle plantar flexion (GJ:2.6±0.3, BJ:2.2±0.2) were significantly higher in GJ compared to BJ. However, there were no significant differences observed in positive work, negative work, mechanical power, and all joint kinematic and kinetic data. On the other hand, in ankle joint MVC, joint peak torque at -15 degrees (GJ: 1.2±0.1, BJ: 1.0±0.2), 20 degrees (GJ: 2.2±0.4, BJ: 1.8±0.2), and 25 degrees (GJ: 2.0±0.3, BJ: 1.6±0.2) showed significantly higher values in GJ.

CONCLUSION: The difference in ankle joint torque at 20 and 25 degrees between GJ and BJ suggests the importance of exerting and maintaining force during dorsiflexion from the peak of GRF until the peak of GRF following the onset of ankle joint plantar flexion. Therefore, the ankle joints ability to maintain the negative work acquired up to the beginning of the propulsive phase while exerting additional force during push-off at the ankle joint may be a determining factor in jump performance. Especially within this interval, which can be predicted to be situated near the descending limb of the force-length relationship, our results suggest the necessity of ankle joint-specific training closer to the actual angle where the concentric phase begins to enable force exertion near optimal length.

IMPROVEMENT PATTERN OF NEUROMUSCULAR PERFORMANCE IN RELATION TO GROWTH IN ATHLETES AND NON-ATHLETES

PETRIDIS, L., PÁLINKÁS, G., TRÓZNAI, ZS., UTCZÁS K.
HUNGARIAN UNIVERSITY OF SPORT SCIENCE

INTRODUCTION: Substantial increase in neuromuscular performance has been reported around the age at peak height velocity (APHV). This improvement seems to follow a natural pattern, which is similar in both athletic and non-athletic populations. Little is known, however, whether regular and high-level training can further improve neuromuscular performance, beyond the improvement attributed to natural development. The purpose of this study was to compare the developmental pattern of neuromuscular performance in relation to growth between athletes and non-athletes.

METHODS: Data from 684 athletes (mean±sd age: 14.0±1.4 years) and 120 non-athletes (mean±sd age: 13.4±1.5 years) were analyzed. All athletes were engaged in high-level sport-specific training and competition (>8 hours/week) in soccer, handball, or basketball. Non-athletes were not engaged in any regular sport activity outside of their school curriculum. Maximal countermovement jumps were performed on a force platform (HUR labs). Jump height, force, power, and the modified reactive strength index were included in statistical analysis. APHV was used to estimate maturity status. Based on the years from peak height velocity (PHV), we divided the participants into groups of one year interval from -2 years to +2 years around PHV. Descriptive statistics and two-way ANOVA was used for inter-group comparisons.

RESULTS: On average athletes achieved significantly higher jump height compared to non-athletes (mean±sd CMJ: 33.2±5.5 cm vs. 28.3±6.1 cm respectively, $p<0,05$; d=0.88). Improvement rate from the youngest to the oldest PHV group was 38.1% for the athletes and 36.5% for non-athletes. Differences between athletes and non-athletes were of small to moderate effect size (d=0.48-0.62) before APHV and of moderate to large (d=0.62-0.90) effect size after APHV. There was no difference in the in-PHV group (mean±sd CMJ: 32.0±4.9 cm vs. 31.5±6.7 cm respectively, $p>0.05$; d=0.1). Similar results were found for the relative maximal power.

CONCLUSION: A period of accelerated improvement in neuromuscular performance was found ±1 year around the APHV with similar improvement rate in both groups. However, in the most intense improvement period (in-PHV group) the lack of differences suggest that sport-specific training (in the examined sports) does not provide further improvement beyond that attributed to growth. Training stimuli seems to account for additional improvements in neuromuscular performance mainly in the period after the APHV, with athletes achieving increasingly larger performance one and two years after their APHV (around 14 -16 years of chronological age) compared to non-athletes.

DETERMINANTS OF TIME TO EXHAUSTION DURING HIGH-INTENSITY INTERVAL TRAINING

BOSSI, A.H., HOPKER, J.
EDINBURGH NAPIER UNIVERSITY

INTRODUCTION: The relationship between cycling power output and time to exhaustion (TTE) displays a curvilinear form that can be linearised by employing the logarithm of TTE. This relationship persists even for exhaustive intermittent exercise, wherein high- and low-intensity intervals of fixed power and duration are alternated. While training status, body dimensions, and sex influence the power outputs someone can generate, seemingly comparable cyclists can still manifest considerable inter-individual variability in TTEs. This study explored which factors might contribute to longer TTEs during high-intensity interval training (HIIT).

METHODS: The dataset of Bossi et al. (2023) was reutilised. Sixteen male and two female competitive cyclists (age: 38 ± 11 years, maximal oxygen uptake (VO2max): 54 ± 9 ml·kg-1·min-1) performed an incremental test, two 3-min all-out tests, and two 20-min time trials to establish physiological and performance benchmarks after a familiarisation (visits 1 and 2). Then, in randomised order, participants performed four HIIT sessions to exhaustion at power outputs associated with different intensity prescription methods (visits 3 to 6). HIIT sessions consisted of 4-min work intervals interspersed with 2-min active recoveries. The natural logarithm of TTE in seconds was modelled using linear mixed models, with participant as a random effect, and HIIT power output, age, height, body mass, the maximal scores in the incremental test (VO2max, power output, heart rate, respiratory exchange ratio, respiratory rate, rating of perceived exertion, blood lactate concentration), the power outputs associated with the gas exchange threshold and respiratory compensation point, critical power, work capacity above critical power, time trial mean power output, and estimated vastus lateralis adipose tissue thickness as fixed effects. The best model was selected based on Akaike information criteria. Significance was set at $P \leq 0.05$.

RESULTS: The best model revealed that HIIT power output, VO2max, and maximal respiratory exchange ratio (RERmax) are all determinants of TTE, with the first two emerging as primary factors. Specifically, with an intercept of 11.309 (SE = 3.292), a unit increase in power output reduces the log transformed TTE by 0.032 (SE = 0.003). Conversely, a unit increase in VO2max extends the log transformed TTE by 2.267 (SE = 0.277). A decimal unit increase in RERmax reduces the log transformed TTE by 0.277 (SE = 2.621). The model indicated considerable inter-individual differences, with a SD of 0.460 for the intercept. The SD for the residual variability was estimated as 0.318.

CONCLUSION: Besides the expected effect of the power output target for HIIT, it seems that individuals with higher VO2max, attained with lower RERmax, are more likely to produce longer TTEs. A complex interplay of attributes, possibly involving unexplored factors, complicates the individualisation of HIIT prescription.

ACUTE EFFECTS OF TRANSCRANIAL DIRECT CURRENT STIMULATION (TDCS) ON EXERCISE TOLERANCE AND THE PHYSIOLOGICAL RESPONSES TO HEAVY- AND SEVERE-INTENSITY EXERCISE

DELL ANNA, S., BERNARDES, A.G., IVANISKI-MELLO, A., LIBERALI, G., MARTINIS, L., CORREALE, L., PEYRÉ-TARTARUGA, L.A., MACHADO, F.A., COSENTINO, G., DE GIORGIO, A., BALDARI, C., BUZZACHERA, C.F.
ECAMPUS UNIVERSITY, ITALY; FEDERAL UNIVERSITY OF RIO GRANDE DO SUL, BRAZIL, UNIVERSITY OF PAVIA, ITALY; STATE UNIVERSITY OF MARINGÁ, BRAZIL, IRCCS MONDINO FOUNDATION, PAVIA.

INTRODUCTION: Transcranial direct current stimulation (tDCS) has emerged as a minimally invasive form of cortical stimulation, with exciting potential for exercise performance. While some studies have confirmed the apparent ergogenicity of tDCS during continuous, large muscle-mass exercise, not all findings are consistent. The variable results between tDCS studies may be attributed, at least in part, to differences in exercise intensity. We, therefore, investigated the effects of acute tDCS on exercise tolerance and the physiological responses to heavy- and severe-intensity exercise

METHODS: Twelve healthy, recreationally active men (mean age ± SD = 25 ± 2 yr, VO2peak 50 ± 8 ml/kg/min) volunteered to participate in this study. All participants were required to report to the laboratory on five separate occasions. On Day 1, they performed a ramp incremental exercise test on an electronically braked cycle ergometer to determine gas exchange threshold (GET), VO2peak, and peak power output (PPO). On Days 2-5, participants received, in a random and crossover order, 20 minutes of brain stimulation of either sham tDCS or anodal tDCS (current intensity: 2 mA) before either heavy- or severe-intensity cycling exercise. Pulmonary exchange and ventilation data, NIRS-derived muscle oxygenation and hemodynamics responses, and surface EMG signals were recorded throughout the exercise bouts. Ratings of perceived exertion (RPE) were also assessed every 2 min in each exercise bout

RESULTS: No significant effects of brain stimulation on exercise tolerance were observed (261 ± 56 sec and 258 ± 59 sec for sham tDCS and anodal tDCS, respectively; $P > 0.05$). Anodal tDCS did not induce significant changes in pulmonary gas exchange and ventilation parameters, NIRS-derived muscle oxygenation and hemodynamics responses, or muscle fibre

conduction velocity during heavy- and severe-intensity exercise compared to sham tDCS (P > 0.05). Similarly, RPE did not significantly differ between the brain stimulation conditions at any time in both exercise intensities (P > 0.05)

CONCLUSION: Our findings indicate that acute brain stimulation with anodal tDCS applied over the primary motor cortex (M1) does not appreciably alter physiological responses to heavy- and severe-intensity exercise or improve exercise tolerance in healthy, recreationally active men. These results support the notion that this simple, minimally invasive neuromodulatory technique may not be effective during continuous, high-intensity, large muscle-mass exercise

NEGATIVE IMPACT OF 14 DAYS OF STEPS REDUCTION ON MUSCLE OXIDATIVE CAPACITY IN YOUNG PARTICIPANTS

MARCIANO, A., NERI, M., CRECCHI, M., SAZZI, C., BROCCA, L., PELLEGRINO, M.A., BOTTINELLI, R., PORCELLI, S.
1 DEPARTMENT OF MOLECULAR MEDICINE, UNIVERSITY OF PAVIA, PAVIA, ITALY

INTRODUCTION: Inactivity negatively affects cardiorespiratory and muscle functions, decreasing exercise tolerance and dramatically increasing disease risks [1]. Previous data showed a time-dependent impairment of muscle oxidative capacity after severe inactivity (bed rest, BR) [2-4]. No changes in mitochondrial function were observed after 7 days of step reduction (SR) [5], a milder inactivity model. Therefore, we investigated the negative impact of 14 days of SR on muscle oxidative capacity estimated by near infrared spectroscopy in young participants. We hypothesized a longer period of SR could negatively affect muscle oxidative function.

METHODS: Thirty (23±3 yr; 68±10 kg; 170±7 cm) participants followed a 14 days SR protocol. Before (T1) and after (T2) inactivity, whole-body oxygen uptake (VO2max) was measured during incremental cycling exercise. Vastus lateralis muscle oxygen uptake recovery rate constant (k) was calculated from tissue oxygen saturation index (TSI) changes during repeated transient occlusions performed immediately after leg-extension exercise. Time of ischemia-reperfusion for the occlusions was manipulated to maintain TSI in non-limiting O2 availability condition. Muscle biopsies were also collected and high resolution respirometry (HRR) was performed.

RESULTS: SR resulted in an 82% reduction of participants' average daily steps. VO2max was significantly reduced after SR (-4.4% from T1; p 0.022). k was significantly lower in T2 (2.1±0.6 min-1) compared to T1 (2.3±0.6; p=0.031). HRR was not different after inactivity (p>0.05).

CONCLUSION: Our data confirm that, after a mild reduction in daily activity for two weeks, whole body maximal oxygen uptake loss is related to limitations in oxygen flow at skeletal muscle level measured in-vivo. The absence of changes in maximally [ADP] stimulated mitochondrial respiration and other respirometric parameters after SR, which confirm previous data after 10 days bed rest interventions [4], raises interests towards other assessments of mitochondrial function, such as sensitivity of mitochondrial respiration to sub-maximal [ADP], and impairments upstream of mitochondria.

OP-MH11 Injury Prevention in female athletes

INJURIES IN WOMEN AND MEN HANDBALL PLAYERS, WHAT DO COACHES NEED TO KNOW? A COMPREHENSIVE ANALYSIS OVER 3 SEASONS AND 154 GAMES

ANDREOTTOLA, G., ONGARO, A., FERREIRA, J., CROGNALE, D.
UNIVERSITY COLLEGE DUBLIN, OLYMPIC HANDBALL IRELAND

INTRODUCTION: Handball is a fast-paced Olympic ball game characterized by both defensive and offensive actions aimed at scoring goals. Performance in handball is influenced by a multitude of factors and it involves a range of actions including throws, passes, jumps, hits, blocks and runs. Athletes may experience muscle injuries such as strains and tears due to the rapid movements and accelerations during the game. Furthermore, collisions with opponents and physical contact can lead to traumas such as bruises, contusions and joint sprains. Handball players are also at risk of upper limb injuries, particularly to the hands and wrists, due to the fastball throws and passes. The aim of this study was to monitor number and details of injuries occurring during official Handball matches to enhance current knowledge, awareness and understanding for coaches and practitioners.

METHODS: A total of 154 matches of women's and men's handball (across 3 seasons - 21/22, 22/23, 23/24) from the national league, national cup and Celtic league of Ireland were analyzed by two independent and experienced sport scientists. A comprehensive report of all injuries, regardless of severity was compiled for the three seasons according to injured body part/region or joint.

RESULTS: The data collection resulted in a total of 58 recorded injuries. Despite logistical constraints, key findings reveal a 40% probability of injury during matches, with knee (22.5%), ankle (19%), face (14%), neck (5%), and the face-neck-head complex (20%) injuries being predominant. 60% of injuries occurred in female players (21/22 14W, 8M; 22/23 19W, 10M; 23/24 5W, 2M)

CONCLUSION: A gender disparity was evident, indicating a potential need for gender-specific physical preparation and awareness by players, coaches, and practitioners. This analysis also highlighted a need for higher accuracy and consistency when reporting handball injuries and ideally including a comparison with other European leagues and competitions.

UNDERSTANDING MUSCLE INJURIES IN ELITE FEMALE FOOTBALL: ARE THEY THE BIGGEST THREAT TO KEEPING PLAYERS PLAYING?

BENNETT, F., MATERNE, O., RAMSDEN, J., GRIFFIN, P., BROWNLEE, T., DRUST, B.

RANGERS FOOTBALL CLUB

INTRODUCTION: Female professional footballers present a high incidence of thigh muscle injuries with a meaningful burden (1). Injuries in elite women's football are scarcely investigated and no study has been conducted in the highest competitive level in Scotland (1,2). The aim of this study was to examine the extent and pattern of non-contact muscle injuries (Nc-Mi), and their respective incidence and burden in a professional female football team playing in Scottish Women's Premier League (SWPL 1).

METHODS: During the 2022-23 season, all injuries that required medical attention (0 day) or led to time-loss were recorded prospectively (as per IOC consensus definitions) by the medical team of the club in 30 unique professional female footballers (mean age: 23 ± 5 years). Nc-MI incidence was calculated as the number of injuries per 1000 playing hours and injury burden as the number of days lost per 1000 hours.

RESULTS: A total of 393 injuries were recorded, 255 (65%) were non-contact lower limb injuries, of which 77% (n=196) were Nc-Mi. This reflects an incidence of 48.3 (95% CI 41.8 to 55.6) injuries per 1000h and a nearly tenfold higher incidence of no time-loss compared with time-loss injuries (43.6; 95% CI 37.4 to 50.5 vs 4.7; 95% CI 2.8 to 7.3). Burden of acute onset injuries was significantly greater than gradual onset (33.3 days vs 16.3 days per 1000h, p<0.0001). Injury incidence (11.9; 5.7-21.8 vs 2.8; 1.3-5.3) and burden (160.3; 134.4-189.7 vs 20.5; 15.9-26.1) were higher for match compared to training (p<0.0001). Hamstring injuries had the highest match injury burden (90.2 days lost per 1000h), the most burdensome muscle injury in training was the quadriceps (14.3 days lost per 1000h).

CONCLUSION: Consideration of time loss injuries only might limit the understanding of potential training load errors on player's musculoskeletal system. The high prevalence and incidence of no-time-loss muscle injuries, particularly of gradual onset indicates the necessity to reflect on them to enhance the understanding of load stimuli response. A greater quadriceps injury burden occurring in training differs from the greater burden of hamstring injuries occurring in matches. Muscle injury risk reduction strategies may therefore be tailored by muscle group on an individual basis, considering the context and type of onset in order to develop an optimal player robustness to lower limb non-contact muscle injuries.

(2024) 'UEFA Women's Elite Club Injury Study: A prospective study on 1527 injuries over four consecutive seasons 2018/2019 to 2021/2022 reveals thigh muscle injuries to be most common and ACL injuries most burdensome', British Journal of Sports Medicine [Preprint]. doi:10.1136/bjsports-2023-107133.

EXPLORING WORKLOAD-RELATED INJURY RISK FACTORS IN ELITE FEMALE VOLLEYBALL PLAYERS

MASHIMO, S., SAKAGUCHI, M., TAKEGAMI, A., HOGAN, T., YOSHIDA, N.

RITSUMEIKAN UNIVERSITY

INTRODUCTION: Monitoring athletic workloads and athletes' responses is important to minimise injury risk and maximise athletic performance [1]. The relationship between workload and injury has been studied in numerous outdoor sports, such as football and rugby; however, studies on indoor sports, including volleyball, are limited [2]. This study aimed to investigate potential workload-related injury risk factors in elite female volleyball players.

METHODS: From June 2022 to March 2023, 19 Japanese female volleyball players were followed prospectively. Every Sunday, injuries were measured using the Japanese version of the Oslo Sports Trauma Research Center (OSTRC) Questionnaire on Health Problems (OSTRC-H2.JP) [3]. The prevalence of all injuries and substantial injuries were calculated once weekly and presented with 95% confidence interval (CI). Workloads were monitored daily using the session rating of perceived exertion (sRPE) as the internal load and total jump height recorded by VERT 3.0 (Mayfonk Inc., Fort Lauderdale, FL, USA) as the external load. The acute:chronic workload ratio (ACWR) was calculated by dividing acute load (7-day) by chronic load (21-day and 28-day) with a rolling average (RA) and exponentially weighted moving average (EWMA) calculations and coupled and uncoupled approaches. The association between workload and injury was determined by random-effects logistic regression models. Multicollinearity was verified by variance inflation factor (VIF).

RESULTS: The OSTRC-H2.JP average response rate was 85.0% throughout all weeks. The average weekly prevalence of all injuries was 51.4% [95% CI; 47.6–55.2%], of which 13.9% [95% CI; 11.0–16.9%] were considered substantial. The most affected body parts of injuries were the knee (n = 19, 15.8%), hip/groin (n = 12, 10.0%), and thigh (n = 12, 10.0%). After checking for no multicollinearity that VIF ≤ 5, three candidate variables (7:21/internal/coupled/EWMA, 7:21/external/coupled/EWMA, 7:28/external/coupled/EWMA) were included in the random-effects logistic regression model. Adjusted odds ratios (aORs) of workload variables were 0.99 (7:21/internal/coupled/EWMA, 95%CI; 0.33–2.96),

3.84 (7:21/external/coupled/EWMA, 95% CI; 1.21–12.17), and 0.94 (7:28/external/coupled/EWMA, 95% CI; 0.38–2.36), of which "7:21/external/coupled/EWMA" was a significant injury risk factor.

CONCLUSION: In this study, >50% of elite female volleyball players experienced symptoms of injury. Moreover, one in 10 participants presented substantial injuries that affected their sports participation and performance. The external workload was associated with the occurrence of injury; 7:21 ACWR if using a coupled approach and EWMA calculation. Therefore, monitoring external workload is essential to prevent injuries in elite female volleyball players.

THE INFLUENCE OF THE MENSTRUAL CYCLE PHASES ON SINGLE-LEGGED FUNCTIONAL BALANCE AND JUMP TESTS IN FEMALE AMATEUR FOOTBALL PLAYERS

SCINICARELLI, G., WILKE, C.

GERMAN SPORT UNIVERSITY COLOGNE

INTRODUCTION: The different hormonal levels during the female menstrual cycle phases could negatively influence the athletic performance of female athletes, especially during the first (follicular) than the second (luteal) phase. Consequently, this can increase the susceptibility to lower extremity injuries. The ability of single-leg balance or jumping are fundamental variables in order to succeed in professional and amateur sports. The aim of this study was to observe differences in functional performance tests between the two phases of the menstrual cycle in female football players.

METHODS: Cross-sectional study. 17 female amateur football players (26.82 ± 5.39 years) were tested twice during the follicular (T1) and luteal (T2) phase of the menstrual cycle by using the Y-Balance Test and the Single-leg Jump for Distance Test.

RESULTS: No significant differences in single-leg functional performance between the follicular and luteal phases have been found for both tests ($p > .05$).

CONCLUSION: The different menstrual cycle phases have no influence on functional performance tests in female football players. Therefore, specific preventive training programs focused on balance and jumping skills are recommended during the entire menstrual cycle. Finally, further studies should ensure a more valuable injury prevention approach by the inclusion of motion quality analyses during the menstrual cycle phase.

THE LIVED EXPERIENCES AND SIGNIFICANT CHALLENGES ON LIFESTYLE AND WEIGHT MANAGEMENT FACING PAEDIATRIC PATIENTS WITH DEMYELINATING CONDITIONS

CONSTERDINE, A., CHAPMAN, K., COLLETT, J., DUDA, J.L., DAWES, H.

LIVERPOOL JOHN MOORES UNIVERSITY

INTRODUCTION: Demyelinating syndromes (DS) are chronic, relapsing, autoimmune conditions characterised by inflammation and damage to the nerves in the brain and central nervous system). Although DS disorders such as Multiple Sclerosis and Neuromyelitis Optica Spectrum Disorder (NMOSD) are prevalent in the adult population, paediatric onset is rarer and much less studied. These lifelong conditions have severe implications for quality of life, impacting on school performance and social activities, as well as physical, emotional and psychological well-being. Two particularly concerning aspects of these conditions are that they are often accompanied by drastic weight changes and alterations to body composition.

METHODS: 16 young people with DS took part in semi-structured interviews, conducted virtually and audio recorded. Questions related to how the condition has impacted their lifestyle, diet, and physical activity levels. Inductive thematic analysis was employed for data analysis. Rigour and credibility were established through detailed immersion and prolonged engagement of the data, multivocality, member reflections, reflexivity and inter-researcher debriefing.

RESULTS: Six overarching themes were identified: 1) the influence of the diagnosis on the young person, 2) the implication of the treatment, access to services and effects of steroids, 3) the ways in which the young person mediated the effects of their condition through changes to their diet, physical activity/lifestyle and vice versa, 4) the impact of sleep quality on fatigue levels, 5) a change of identity associated with living with a debilitating lifelong condition, and 6) the influence of family.

CONCLUSION: Diagnosis and treatment produced a multitude of intersecting effects on the young people interviewed. Patients fell into three distinct groups, namely some who were very active prior to diagnosis and were highly motivated to strive for activity maintenance post diagnosis. Some patients were not physically active either pre or post diagnosis and struggled to manage their disease course. A third group were moderately active before diagnosis, and then struggled to maintain activity levels or weight after. Some patients in the latter two groups underwent an epiphany leading to a dra-

matic change in their lifestyle and physical activity levels. The data suggested a range of both facilitators and barriers to being physically active with associated behavioural or emotional responses to the diagnosis, treatment and effects of the conditions. Some of these included the effects of family on diet and lifestyle, peer support, motivational disposition, fatigue, stress, fear of physical activity, alienation from their own bodies, fear of exercise exacerbating symptoms, or access to relevant resources or sources of information. Those who maintained or improved their physical activity levels, were able to manage their disease course more adroitly, taking ownership of their condition, with an improvement in well-being.

PHYSICAL ACTIVITY TRAINING PRESERVES EXERCISE TOLERANCE AND SKELETAL MUSCLE OXIDATIVE CAPACITY IN PATIENTS WITH PARKINSON'S DISEASE

NERI, M., GATTI, M., DE ICCO, R., BIGHIANI, F., MARTINIS, L., PISANI, A., CALCULLI, A., COMOLLI, D., FAZIO, C., BOTTINELLI, R., PORCELLI, S.

UNIVERSITY OF PAVIA

INTRODUCTION: Parkinson's disease (PD), the second most common neurodegenerative disease, is characterized by an irreversible loss of dopaminergic neurons in the substantia nigra pars compacta of the basal ganglia, which affects the nervous system, causing motor disturbances (bradykinesia, resting tremor, rigidity, postural instability and gait impairment) [1,2].

Despite it is not clear how alterations in central or peripheral nervous systems controlling skeletal muscle can influence muscle function, PD patients show mitochondrial impairments at skeletal muscle level which can be counteracted by exercise, reducing symptoms and improving patients' quality of life [1,3,4].

The aim of the study was to highlight the beneficial effects of physical activity training on exercise tolerance and skeletal muscle oxidative capacity in PD patients.

METHODS: Eleven trained (PD-TR, age: 58±6 years, disease duration: 8.3±6.4 years) and six sedentary (PD-SED, age: 65±10 years, disease duration: 3.7±2.0 years) PD patients were recruited. The level of physical activity was rated by means of IPAQ-Short. Each subject performed an incremental exercise test on a cycle ergometer up to exhaustion to determine Wpeak and V'O2peak. Vastus lateralis (VL) fractional O2 extraction (DHHbMb), non-invasively evaluated by near-infrared spectroscopy (NIRS), was recorded and expressed as % of a reference value obtained during a transient ischaemia of lower limb [5]. Muscle oxidative capacity (mVO2) of VL was estimated by NIRS from recovery rate constant (k) of TSI changes during brief intermittent arterial occlusions [6].

RESULTS: Wpeak and V'O2peak were higher in PD-TR (232±52 W and 40.1±4.8 ml*kg-1*min-1, respectively) compared to PD-SED (146±36 W and 21.0±1.7 ml*kg-1*min-1, respectively; $p<0.01$). DHHbMb was higher in PD-TR (68.2±17.1 %) compared to PD-SED (32.4±13.5 %; $p<0.01$). k was higher in PD-TR (2.52±0.82 min-1) compared to PD-SED (1.39±0.51 min-1, $p<0.01$). A correlation was found between DHHbMb and k ($r=0.77$; $p<0.001$).

CONCLUSION: The present findings confirm regular physical activity training improves exercise tolerance in PD patients, mainly through an improved muscle oxidative metabolism.

AEROBIC EXERCISE VS COMBINED COGNITIVE AND AEROBIC EXERCISE IN PEOPLE WITH PARKINSON'S: EFFECTS ON COGNITION AND BIOMARKERS OF NEUROPLASTICITY

FERRUSOLA PASTRANA, A., DAVISON, G., JAVADI, A.H., FULLERTON, C., MEADOWS, S.

EUSES - UDG

INTRODUCTION: Neuropsychological impairments, such as cognitive decline, mild cognitive impairment or dementia, are common in PwP and can impact their daily activities and quality of life. Pharmacological procedures have limited effects to treat those, and research suggests that non-pharmacological interventions, such as exercise or cognitive training, could have the potential to improve cognition. Considering the efficacy of exercise to also promote physical and cognitive improvements, the implementation of the combined modalities could be more beneficial than single-domain training. Aim: to investigate BDNF and pro-BDNF kinetics in PwP during different acute exercise interventions and their relationship with measures of cognitive function, with the overall aim to evaluate if there are added beneficial outcomes from combining physical and cognitive tasks compared to engaging with aerobic exercise only.

METHODS: 6 participants (age 61 ± 12 years; Hoehn and Yahr (H&Y) scale I to II) participated in 4 supervised conditions: a session of acute cycling (A), a second acute cycling session 24 h. after A (B), combined acute session of cycling and cognitive tasks (C) and a resting condition (D). In A, B and C participants completed 30 min of cycling at RPE 14 on a cycle ergometer. Outcome measures included blood and saliva biomarkers (BDNF and pro-BDNF) and measures of cognition (the Stroop test and the Free-Recall test).

RESULTS: Visits B (second) and C (combined) were able to elicit larger improvements in the Stroop test with large (d=0.853) and small to medium (d=0.349) effects, respectively, and up to 30 and 40% improvements, respectively, in immediate long-term memory (LTM) compared to the resting control visit D. Serum and capillary BDNF levels were positively correlated with cognitive performance, whilst platelet-poor plasma BDNF correlations seemed to be headed in the opposite direction.

CONCLUSION: Due to the small sample size of this preliminary study, there was poor sensitivity to detect effects in cognition even though medium to large effect sizes were observed for some comparisons. Therefore, it is not yet fully known to what extent cycling combined with cognitively challenging tasks, compared to cycling alone, improves cognitive function and modulates biomarkers of neuroplasticity in PwP.

ENHANCING TELEHEALTH PROFICIENCY: TRAINING NEEDS OF AUSTRALIAN ALLIED HEALTH PROFESSIONALS IN EXERCISE AND BEHAVIOURAL CHANGE FOR MS THERAPY

MAVROPALIAS, G., BAYNTON, S.L., TEO, S.Y.M., DONKERS, S.J., VAN RENS, F.E.C.A., LEARMONTH, Y.C.

MURDOCH UNIVERSITY

INTRODUCTION: Exercise reduces the severity of multiple sclerosis (MS) symptoms, and may play a crucial role in overall disease management. When people with MS seek exercise guidance, they approach their allied health professionals (AHPs) [1,2]. We investigated the proficiency, knowledge gaps, and training needs and wants of Australian AHPs in telehealth exercise therapy and behavioral change for people with MS. We focused on identifying the educational needs of AHP to optimise professional development training programs.

METHODS: We conducted an online survey engaging 58 AHPs, including 34 physiotherapists, 14 exercise physiologists, and 10 occupational therapists, to assess their current telehealth practices, confidence levels, and training preferences related to exercise and behavioral change for MS. The survey, incorporated multiple-choice, Likert scale, and open-ended questions. Responses were analysed through binary and multinomial logistic regression.

RESULTS: One third of AHPs (33%) displayed a lack of awareness regarding MS exercise guidelines [3], with occupational therapists being the least familiar (60% unfamiliarity). Despite 93% of all AHPs acknowledging the distinction between physical activity and exercise, only 14% could provide accurate and complete definitions. Most AHPs (91%) used physical activity behavioral change strategies, with goal setting being predominant. However, over a quarter (27.6%) of AHPs felt unprepared in promoting exercise to MS clients, with occupational therapists notably the least confident in prescribing and adjusting telehealth exercise programs (90% uncertain). Most AHPs (96.3%) expressed a need for further training, particularly in online self-paced formats, focusing on MS-specific exercise prescription, behavioral change methods, and telehealth delivery techniques.

CONCLUSION: The study underscores a considerable need for specialised, profession-specific training programs among Australian AHPs, especially to augment confidence and competence in telehealth exercise therapy and behavioral change for MS. Such education, ideally delivered through online workshops, will not only address the knowledge gaps but also align with AHPs preferences for self-paced learning. Furthermore, these programs should be developed with a keen understanding of the AHPs current practice environment and healthcare system, ensuring practical applicability and relevance in their daily professional settings. This approach will significantly contribute to the advancement of telehealth practices in MS care, ensuring a higher standard of patient-centered, evidence-based treatment.

HEAT ILLNESS COMPLICATED BY HYPONATRAEMIA: IS NON-CLASSIC CONGENITAL ADRENAL HYPERPLASIA AN UNDER-RECOGNISED CAUSE OF EXERTIONAL INCAPACITY?

STACEY, M., HOUSE, C., ROIZ DE SA, D., GRIST, D., BOOT, S., ALLSOPP, A., WOOD, D.R.

LEEDS BECKETT UNIVERSITY

INTRODUCTION: With exercise in the heat, impaired evaporative cooling from hypovolaemia may predispose Exertional Heat Illness (EHI), risking debility and even death. Non-classic congenital adrenal hyperplasia (NCCAH) is caused most

commonly by mutations leading to deficiency in the adrenocortical enzyme 21 hydroxylase (21OHD) and, despite a carrier frequency of 1:25 or more, is one of the most under-recognised autosomal recessive disorders. Typical presenting features of NCCAH arise from adrenal androgen excess, however with sustained stress, parallel defects in gluco- and mineralocorticoid production might be observable. Under sustained heat load, this would have the potential to precipitate EHI from depletional hyponatraemia.

METHODS: United Kingdom military personnel were recruited from three groups referred to a specialist heat illness clinic: those with no history of EHI (controls, n=16), those affected by EHI with no documented hyponatraemia (nEHI, n=16), and cases of EHI complicated by hyponatraemia during deployment from the UK to hot climates (hEHI, n=2). After defining VO2peak, exercising Heat Tolerance Test (HTT) was conducted at 60% relative intensity, in WBGT 27 degrees C. Responses were categorised as pass (heart rate and core temperature plateau) or fail (inability to demonstrate thermal equilibrium at 90 min). Blood was sampled for steroid analysis at rested baseline, post-VO2peak and post-HTT, and with Short SynACTHen Test (STT) to characterise adrenal reserve. On clinical grounds, EHI cases failing HTT were re-tested following a minimum of 12 weeks, and mutations causative of NCCAH, including 21OHD, were sought in hEHI.

RESULTS: HTT was passed at first attempt by 15/16 controls and 11/16 nEHI, with 100% pass rate on re-testing. One hEHI passed HTT first-time and, on genotyping, exhibited carrier status for 21OHD. The other hEHI required two subsequent attempts to pass HTT. Upon re-deployment into climatic heat, he was again thermally intolerant and was referred back for HTT, which he passed, however he was found also to have NCCAH (21OHD homozygote). No participants were shown to have inadequate adrenal reserve in cooler UK conditions, including hEHI with 21OHD mutations. Nevertheless, significant shunting of steroid precursors away from cortisol and aldosterone production was shown in NCCAH, both with HTT and on SST.

CONCLUSION: Genotyping for NCCAH caused by 21OHD and other related enzyme defects may be warranted in athletes and military personnel who develop EHI complicated by hyponatraemia, especially where preceding thermal stress was extreme and sustained. The positive predictive value of HTT for future heat intolerance requires further investigation in this population.

HEAT TRAINING PROTOCOLS: ARE INTERMITTENT OR CONTINUOUS CYCLING PROTOCOLS MORE BENEFICIAL FOR INDUCING A GREATER THERMOREGULATORY RESPONSE IN FEMALES?

KELLY, M., BOWE, S.J.1,2, BARNARD, J.G.1, CONDO, D.1, GUY, J.H.3, SNOW, R.J.1, CARR, A.J.1

INTRODUCTION: There is evidence that heat acclimation is beneficial in females [1], but it is unclear if intermittent exercise in the heat elicits greater adaptation than work-rate matched continuous exercise. We therefore investigated two different short duration, intermittent work:recovery intervals (compared with continuous exercise) on females' rectal and skin temperatures and heart rate during exercise in the heat.

METHODS: Fourteen recreationally trained females (mean ± SEM: age 29.8 ± 1.7 yr; body mass 68.73 ± 1.51 kg; body surface area 1.80 ± 0.03 m2) completed three 60-min cycling-based sessions in the heat (~39°C, ~40% relative humidity, ~1.40 m.s-1 air speed) with mean external work rate matched between protocols (~239 W.m-2) designed to elicit a mean exercise intensity of ~60%VO2max. The exercise protocols were 1) continuous (CON), 2) 90:90-sec and 3) 30:30-sec work:recovery intervals. Key outcome measures of rectal temperature (Trec), skin temperature (Tskin; °C), and heart rate (HR; beats.min-1) were collected at 30-sec intervals and expressed as mean values over each 3-min block. The change in Trec and Tskin (end-exercise minus resting values) and change in HR (end of last work block minus resting values) were analysed using linear mixed models and Bonferroni post-hoc procedures were used to locate differences where appropriate. Results were considered statistically significant when $p<0.05$.

RESULTS: Change in Trec was higher in 30:30-sec (1.56 ± 0.10°C) compared to CON (1.17 ± 0.11°C; p=0.001), but not between intermittent protocols (p=0.247) or between CON and 90:90-sec (p=0.141). There was no difference (all p>0.265) in Tskin for CON (4.51 ± 0.49°C), 90:90-sec (4.48 ± 0.50°C), or 30:30-sec protocols (5.03 ± 0.48°C). Change in HR at the end of the last work block was higher in 30:30-sec (105 ± 3 beats.min-1) compared to CON (96 ± 3 beats.min-1; p=0.016), but not between intermittent protocols (p=0.686) or between CON and 90:90-sec (p=0.302).

CONCLUSION: Very short duration, intermittent work:recovery intervals elicited a greater change in Trec and HR compared to work rate-matched continuous exercise in the heat in females. It appears longer duration intervals do not demonstrate a beneficial thermoregulatory response in comparison to continuous exercise for females in the heat. This finding indicates that very short duration, intermittent work:recovery intervals may be an exercise mode to consider in female heat acclimation training protocols for team sports, as it elicits a greater thermal stimulus, possibly driving a faster heat adaptive response in females.

INTRODUCTION: Despite advancements in heat mitigation strategies for athletes, heat related illnesses continue to pose a major risk to athletes' health, particularly in endurance sports. Expert groups and international sporting federations now advocate for athletes' routine monitoring during elite competitions, to ensure their safety. Practical challenges of such initiatives are considerable in sports spanning large distances with multiple exercise modes. Addressing this need, we report on the deployment of wearable technologies for real-time athlete monitoring across multiple World Triathlon events, specifically the 2023 Long-Distance World Triathlon Multisport Championships (LDWTC, Ibiza) and World Triathlon Para Cup (Taranto). The project aims to (i) demonstrate that wearable technologies can help ensure athletes' health and safety (ii) determine the most relevant sensors for use.

METHODS: At the LDWTC, three athletes were monitored. One used a full suite of sensors to measure: core body temperature (TCORE), run kinematics, skin temperature (TSKIN), and heart rate (HR), whilst two were only monitored with TCORE. For run kinematics analyses, the run segment was divided into three equal parts. Environmental conditions were monitored using portable meteorological stations. Data were communicated via a wrist-worn bracelet, transmitting via the cellular network to the cloud. At the Para Cup, seven elite para-triathletes (2 male PTWC [wheelchair users], 1 female [upper limb disability] and 1 male PTS [lower limb disability] and, 2 male and 1 female PTVI [visual impairments]) were monitored for combinations of TCORE, TSKIN, HR and run kinematics.

RESULTS: In Ibiza (ambient temperature 22-25°C), the highest TCORE recorded was 39.52°C (+3.3°C from rest). Across the three segments of the run, the athlete with foot sensors showed gradually shorter stride lengths (1.96 m, 1.72 m, 1.64 m), and increased contact times (233 ms, 251 ms, 259 ms). In Taranto (ambient temperature ~22°C), the highest recorded TCORE was 40.05°C (+2.53°C from rest). Mean core temperature (n=5) was 38.34 ± 0.45°C and mean peak temperature 39.1 ± 0.63°C (+ 1.71± 0.55°C from rest).

CONCLUSION: We implemented a novel multi-sensor monitoring solution during elite triathlon events. High core temperatures at the Para Cup (up to 40.05°C) underscore the need for real-time monitoring. Special attention should be paid to specific populations who are more sensitive to heat illnesses such as athletes with spinal cord injury, for whom real-time monitoring may be even more crucial. A foot-mounted inertial sensor characterised fatigue during the run phase. Further development of integrated multi-sensor approaches, encompassing thermal, cardiovascular, sudomotor, and biomechanical monitoring, combined with multi-location weather data, is needed to accurately predict and prevent heat-related illnesses within elite competition. Future studies in hot environments with a greater sample of athletes should be developed.

THE IMPACT OF NUCLEAR, BIOLOGICAL, AND CHEMICAL PROTECTIVE CLOTHING ON THE PHYSIOLOGICAL RESPONSE OF MILITARY PERSONNEL: METABOLIC EQUIVALENT ANALYSIS AT VARY LOADS AND SPEEDS
